Trypanocidal action and chemical constitution. II. Arylamides of 4-aminophenylarsonic acid. HAROLD KING AND WM. O. MURCH. *J. Chem. Soc.* 127, 2632–51(1925); cf. C. A. 19, 978.—The earlier work showed that, of the arylamides examd, 3'-aminobenzoyl-4-aminophenylarsonic acid was the one to be further developed; this has been done, a series of *p*-substituted *m*-O₂NC₆H₄CO₂H having been prepd., transformed into the acid chloride, condensed with H₂NC₆H₄AsO₂H₂ and reduced. The max. tolerated dose and the min. curative dose on *Trypanosoma equiperdum* in mice are given for several of these compds. Nitration of BzNHC₆H₄AsO₂H₂ at 0° gives 92% of the 3,3'-dinitro deriv. (I), crysts. from 170 parts glacial AcOH as a monohydrate; it forms sparingly sol. Na and K salts. Hydrolysis of I with acid gives a small amt. of *o*-O₂NC₆H₄NH₂, *m*-O₂NC₆H₄CO₂H and 3,4-O₂N(H₂N)C₆H₃AsO₂H₂, though most of I was unchanged after 2 hrs. with 16% HCl; with alkali practically quant. yields of *m*-O₂NC₆H₄CO₂H and 3,4-

$O_2N(H_2N)C_6H_3AsO_3H_2$ were obtained. Reduction of **I** with $FeCl_2$ in $NaOH$ at -5° gives 56% of the 3,3'-diamino compd., clusters of leaflets; the diazo compd. gives with alk. $\beta\text{-C}_{10}H_7OH$ a deep red color. 3',5'-Dinitrobenzoyl-4-aminophenylarsonic acid, needles from 80 parts boiling 90% HCO_2H , in 84% yield from 3,5-(O_2N) $_2C_6H_3COCl$ and $p\text{-H}_2NC_6H_4AsO_3H_2$ (as the Na salt); the max. tolerated dose for mice is 0.5 mg. per g. Attempts to reduce this with $FeCl_2$ in alk. soln. were unsuccessful. 2-Nitro-*p*-toluyl chloride, b_p 167-8° (cor.) and m. 20-1° (cor.). 3'-Nitro-4'-toluyl-4-aminophenylarsonic acid (**II**), needles, in 55% yields; reduction gives 54% of the 3'-amino deriv.; *HCl* salt, needles; *HNO_3* salt, needles; sulfate, square plates. The diazo soln. gives a blood-red color with $\beta\text{-C}_{10}H_7OH$. Nitration of **II** gives the 3,3'-dinitro deriv., needles; hydrolysis with acid gives quant. 4,2-Me(O_2N) $C_6H_3CO_2H$ and 3,4- $O_2N(H_2N)C_6H_3AsO_3H_2$. The 3,3'-diamino deriv., results in 57% yield, forms spherocrystals, gives a yellow diazo soln., which couples with $\beta\text{-C}_{10}H_7OH$ to give a brownish red color. Oxidation of anethole with $KMnO_4$ gives 92% of anisic acid; in alk. soln. at room temp. with 4 atoms O it gave a mixt. of acid and aldehyde; the proportion of acid is increased by carrying out the reaction at 0° . 3-Nitro-4-anisyl chloride, b_p 210°, m. 52.5-3.5° (cor.). 3'-Nitro-4'-anisyl-4-aminophenylarsonic acid (**III**), wooly needles (48.3% yield); the 3'-amino deriv. is obtained in 95% yields; the *HCl* salt, wedge-shaped plates, is most characteristic; sulfate, spherocrystals; nitrate, wooly microneedles; *Ar* deriv. almost insol. in boiling $AcOH$, extremely sol. in 90% HCO_2H , sepg. in anisotropic spherocrysts.; max. tolerated dose for mice, 1.5 mg./g. The *N* formaldehydesulfoxylate was obtained as a powder, from which *HCl* at 50° evolves SO_2 . The carbethoxy deriv. is practically insol. in boiling $AcOH$ but crysts. from 90% HCO_2H in microleaflets, the max. dose tolerated by mice is 0.75 mg./g. The *s*-carbamide crysts. from 90% HCO_2H in microneedles but ppts. from its salts in the gelatinous state. 3''-Nitro-4''-anisyl-3'-amino-4'-anisyl-4-aminophenylarsonic acid, clusters of needles from boiling $AcOH$, the max. tolerated dose for mice being 0.075 mg./g. The 3''-amino deriv., anisotropic solid, results in 75% yields; sulfate, microneedles; nitrate, balls of needles; the max. tolerated dose is 0.02 mg./g. 3''-Nitrobenzoyl-3'-amino-4'-anisyl-4-aminophenylarsonic acid, short, pointed needles from $AcOH$ or square tablets from 90% HCO_2H ; the max. tolerated dose for mice is 0.1 mg./g. The 3''-amino deriv., needles; *HCl* salt, microrods; sulfate, wooly needles; nitrate, anisotropic. Nitration of **III** gave a mixt. of the 3',5'- and 3,3'-dinitro acids, which could not be sepd. by fractional crystn. from 75% $AcOH$ nor by crystn. of the NH_4 salts. The reduction of the mixt. by $FeCl_2$ was unsatisfactory. Hydrolysis of 4-EtOC $_6H_4CN$ with 75% H_2SO_4 gives *Ba* phenol-4-sulfonate, crystg. with 3 H_2O , of which 2.5 are lost in the air; 60% H_2SO_4 for 2 hrs. completely hydrolyzes the nitrite to the acid 3-Nitro-4-ethoxybenzoic acid, m. 200-1°; there also results some 4-nitro- and 2,4-dinitrophenetole. The acid chloride, b_p 215-6°, m. 81-2° (cor.). 3'-Nitro-4'-ethoxybenzoyl-4-aminophenylarsonic acid (**IV**), needles (49% yield); the 3'-amino deriv., wooly microneedles (86% yield); *HCl* salt, small tablets; sulfate, pointed prisms; nitrate, needles; the diazo soln. gives with $\beta\text{-C}_{10}H_7OH$ a bright red color. Nitration of **IV** gives a mixt. of the 3,3'- and 3',5'-dinitro derivs., in the ratio 5:3 as proved by hydrolysis. 4'-Chloro-3'-nitrobenzoyl-4-aminophenylarsonic acid (**V**), needles; this was formed with difficulty, the yield under various conditions varying from 18 to 40%. The 3'-amino deriv. forms leaflets (80% yield); *HCl* salt, oval leaflets; sulfate, square tablets; the diazo soln. gives a bright red color with $\beta\text{-C}_{10}H_7OH$. Nitration of **V** at -5° gives the 3,3'-di- NO_2 deriv., needles; the 3,3'-diamino deriv., pointed plates (76% yield). 4-Ethylcarbonatobenzoic acid, m. 154-6° (94% yield from 4-HOC $_6H_4CO_2H$ and $ClCO_2Et$); 3- NO_2 deriv., m. 168-9° (76% yield); there also results some 4- $O_2NC_6H_4CO_2Et$ and 2,4-(O_2N) $_2C_6H_3CO_2Et$. 3'-Nitro-4'-ethylcarbonatobenzoyl-4-aminophenylarsonic acid, needles (80% yield); hydrolysis gives the 4'-HO deriv., silky needles (97% yield), which is reduced by $FeCl_2$, giving 93.5% of the 3'-amino deriv. (**VI**), needles. From the diazo soln. the diazo oxide seps. as pale yellow needles; it couples with alk. $\beta\text{-C}_{10}H_7OH$ with a cherry-red color. *Na* salt. With Ac_2O and alkali this yields 3'-acetyl-amino-4'-acetoxymethyl-4-aminophenylarsonic acid, soft needles; the max. dose tolerated by mice is 1.75 g./g. *N* $NaOH$ gives the 3'-acetyl-amino-4'-hydroxy deriv., microneedles. **VI** in a mixt. of H_3PO_4 and $AcOH$ gives 3'-amino-4'-hydroxybenzoyl-4-aminoarsenobenzene, amorphous, sol. in $NaOH$ but not in Na_2CO_3 , insol. in HCl but becomes so on addn. of nitrite and then couples with alk. $\beta\text{-C}_{10}H_7OH$. 3-Acetyl-amino-4-acetoxyphenylarsonic acid, needles. **III. Arsonic acids containing the glyoxaline nucleus.** I. E. BALABAN AND HAROLD KING. *Ibid* 2801-14.—Glyoxaline-4(or 5)-carboxyanilide nitrate is dimorphous, both forms crystg. with 0.5 H_2O , unstable fluffy needles and stable, stout prisms, m. 170-1° (decompn.); gradually added to concd. H_2SO_4 at 0° , there results 36 g. of the *p*-nitro deriv. (**I**), crystg. with 2 $AcOH$, m. 307° (cor.).

sol. in 2 *N* NaOH with a pale yellow color (*HCl* salt, crystg. with 1 H₂O, decomp. about 298°; *nitrate*, m 205° (decompn.)) and 14.3% of the *o*-nitro deriv., bright yellow, m. 229° (*HCl* salt, yellow prisms; *nitrate*, yellow, m. 196° (decompn.)). Reduction of I with SnCl₂ and HCl gives the *p*-amino deriv. (II), plates, m 228°; *di-HCl* salt, crystg. with 1 H₂O, blackens about 290°; the diazo soln. couples with alk. β -C₁₀H₇OH with a red color; *chlorostannate*, pale yellow, m. 290° (decompn.); *picrate*, yellow, darkens 256°, decomp. 266°, crystg. with 1.5 H₂O. The *o*-amino deriv. (III), m 270°; *di-HCl* salt, crystg. with 0.5 H₂O, decomp. 310°; *diazoidimide*, m 195-6°, produces no color with alk. β -C₁₀H₇OH; it is very sparingly sol. in H₂O and will detect HNO₂ as a solid cryst. deriv. at a diln. of 1 in 6400 in the presence of AcONa, or, conversely, the amide can be detected at a diln. of 1 in 5000. *Dipicrate*, crystg. with 2.5 H₂O, m 212° (decompn.). II, diazotized and treated with AsO₃ gives 36% of glyoxaline 4' (or 5')-carboxy-*p*-aminophenylarsonic acid, pale yellow, darkens 280°, crystg. from 25% HCO₂H with 1H₂O; *Mg* salt, fine needles, *Ca* salt, anisotropic spherulids; *Na* salt, needles; *HCl* salt, fine needles. Nitration at 0° gives the 3-nitro deriv., yellow plates with 1 H₂O, m. about 327° (decompn.); *Mg*, *Ca*, *Ba* and *Li* salts. Reduction with FeCl₂ in NaOH at -5° gives 86% of the 3-amino deriv., prisms, does not m. 320°; it crysts. with 0.5 H₂O, not lost at 100°. NaNO₂ in a HCl soln. causes the immediate pptn. of the *diazoidimide*, micro-leaflets, which does not couple with β -C₁₀H₇OH; *Mg* and *Ca* salts. 2-*p*-Aminophenylglyoxaline, oil, turns brown on exposure to the air; *di-HCl* salt, prisms, darkens about 300°; *chlorostannate*, needles; *picrate*, orange, decomp. about 239°; no arsonic acid could be prepd. from this compd. 2-*p*-Nitrophenyl-1-methylglyoxaline, pale yellow, m. 116.5° (cor.); *HCl* salt, elongated plates; *chloroaurate*, Au-yellow, decomp. 220° (cor.), soly. 1 part in 300 boiling 3 *N* HCl; *nitrate*, plates, effervescing 186° (cor.); *picrate*, m. 212° (cor.). 2-*m*-Iminophenylglyoxaline, m 203-4°; the monohydrate partly m 130-10° and finally 202-3°; *di-HCl* salt, crysts. with 1 H₂O, m 282° (decompn.); *chlorostannate*, prisms, *picrate*, decomp. 218°. No arsonic acid could be obtained. 2-*o*-Aminophenylglyoxaline, m 136-7°, *di-HCl* salt, m 231-6°, decomp. slightly higher; *chlorostannate*, thin plates; NaNO₂ gives a triazine, m 113-1°, whose *HCl* salt crysts. in needles; it does not couple with alk. β -C₁₀H₇OH; *picrate*, m. 211-2°. 4-*p*-Aminophenylglyoxaline, m 98° (cor.); *di-HCl* salt, darkens 310°; *chlorostannate*, darkens 310°; *dipicrate*, yellow, m 210° (decompn.); the diazo soln. gives an intense purple dye with alk. β -C₁₀H₇OH; but a similar color is obtained with NaOH alone. Pauly's reagent gives an intense red color. Glyoxaline-4 (or 5)-phenyl-*p*-arsonic acid, reddish yellow, does not m 310°; the yield is very small. 4-*o*-Aminophenylglyoxaline, m 131°; *di-HCl* salt, crysts. with 1 H₂O, which is not lost at 95°, effervesce 256°; NaNO₂ gives a bright yellow soln., from which the triazine seps., it is insol. in alkali and does not couple with alk. β -C₁₀H₇OH. *Dipicrate*, decomp. about 200°; normal tartrate, crystg. with 1.5 H₂O and losing 1 H₂O in vacuum over H₂SO₄, m 95-7°, effervesces about 130°; α_{D}^{20} 14.8° (*c* 0.914 in H₂O); *di-d-camphor-10-sulfonate*, m. 198-200°, α_{D}^{20} 21.3° (*c* 1.0 in H₂O). In the action of 28 cc. Me₂SO₄ on 40 g. 2-phenylglyoxaline, there were obtained 32% unchanged product, 18.2% 2-phenyl-1-methylglyoxaline, pale yellow oil, b_{D}^{20} 175° (*HCl* salt, with 2 H₂O); *chloroaurate*, deep yellow, m 189° (cor.), *nitrate*, m. about 100°; *picrate*, m 133° (cor.); *H* ovalate, m 135° (cor.) and, after evapn. of the aq. soln. with HCl, 26.7% of the methochloride, hygroscopic, m. 272° (*chloroaurate*, pale yellow, m. 134° (cor.)). Distn. of the methochloride gave 56% of 2-phenyl-1-methylglyoxaline. The therapeutic action of some of these compds. is given.

C. J. WEST

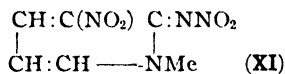

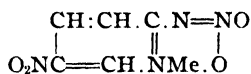

α -Amino- β -picoline and dinitro- α -aminopyridine. Reply to C. R  th. A. E. CHICHIBABIN. *Ber.* 58B, 1707-8 (1925); cf. R. C. A. 19, 1573; R. and Prange C. A. 19, 2823.-C. disputes the claim of R. for priority over Seide (C. A. 19, 518) in the prepn. of α -amino- β -picoline (I) and is convinced that S.'s product, m. 24°, b_{12} 101-2°, and not R.'s, m. 103-4°, b_{11} 113-6°, is the true I. Comparison of C. and Rasorenov's 2-amino-3,5-dinitropyridine (II), m 192° (C. A. 9, 3057), with 5-nitro-2-hydroxypyridine (III) has shown that the 2 compds. are not identical, as claimed by R. and P., and re-analysis of the II has confirmed the results of C. and R. Pure III, m. 186° (cor.). C. A. R.

2-Amino-3-methylpyridine (reply to C. R  th). O. SEIDE. *Ber.* 58B, 1733-4 (1925); cf. R. C. A. 19, 1573.--S. has repeated his prepn. of 2,3-C₅H₃N(NH₂)Me from the purest synthetic β -picoline under the conditions published by R. but has obtained the same results as before. His product, b_{11} 102-3° (cor.), m. 26-6.4°; HCl salt, needles with 1 H₂O, m. 68-75°. R.'s base, m. 103-4°, is apparently α , γ -C₅H₃N(NH₂)Me; in his prepn. he probably used the com. so-called " β -Picolin gereinigt," which as a matter of fact, contains only traces of β -picoline and consists in great part of γ -picoline.

C. A. R.

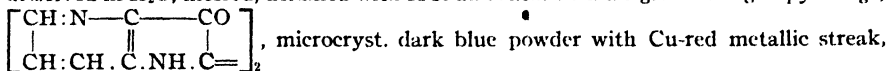

Methylated derivatives of γ -aminopyridine. II. Tautomerism of γ -aminopyridine. A. F. CHICHIBABIN AND E. D. OSSETROVA. *Ber.* 58B, 1708-12(1925); cf. *C. A.* 15, 3109.—The direct action of MeI on α -C₅H₄NNH₂ (I) gives a product (II) yielding with alkalis or moist Ag₂O *N*-methyl- γ -pyridonimine (III); γ -methylaminopyridine (IV) could not be isolated from the mother liquors; the Na deriv. of I with MeI likewise yields chiefly III and no IV. IV can, however, be obtained by treating γ -chlorodipicolinic acid with MeNH₂ and heating the resulting γ -methylaminodipicolinic acid (V) *in vacuo*. Hot concd. alkalis hydrolyze III to *N*-methyl- γ -pyridonimine (VI). *HI* salt (II) of III (4.25 g. from 2.4 g I), m. 187-8°; *picrate*, m. 188-9°; free III, yellowish, b₁₀ 180-1°, solidifies to a very hygroscopic cryst. mass, m. 150-1° which deliquesces and soon turns red in the air, absorbs CO₂ from the air; *chloroplatinate*, red, m. 226-7° (decompn.). VI, obtained by hydrolysis of III or from γ -pyridone and MeI, b₁₃ 230-3°, m. 92-4°; *HgCl₂ compd.*, sinters 120°, m. 177-80° (decompn.). V, gives an intense cherry-red color with FeCl₃ and forms a green flocculent Cu salt IV, m. 115-8°; *chloroplatinate*, orange-red, m. 214-5°; *picrate*, light yellow, m. 168 5-9 0°. C A R.

Nitro derivatives of methylated forms of α -aminopyridine. A. E. CHICHIBABIN AND R. A. KONOVALOVA. *Ber.* 58B, 1712-7(1925).—Nitration of *N*-methyl- α -pyridonimine (I) in cold H₂SO₄ gives a compd., m. 161°, identical with that obtained from Me₂SO₄ and alk. α -C₅H₄NNHNO₂ (*C. A.* 19, 1863) and which undoubtedly is *N*-methyl- α -pyridonenitroimine (II). Concd. H₂SO₄ converts it into the isomer *N*-methyl- β' -nitropyridonimine (III), yellow, m. 181°, also obtained by the action of alkalis on the MeI addn. product (IV) of α , β' -C₅H₃N(NH₂)NO₂. Nitration of α -C₅H₄NNHMe under the above conditions gives a mixt. of NO₂ derivs from which, after treatment with H₂SO₄ as in the isomerization of nitramines, are obtained a compd (V), m. 149°, and III. α , β' -C₅H₃N(NHNO₂)NO₂ (VI) with alk. Me₂SO₄ in the absence of an excess of aq. alkali gives chiefly *N*-methyl- β' -nitro- α -pyridonenitroimine (VII), m. 182°, which in the presence of even very dil. alkalis (Moscow city water) decomp. catalytically into N₂O and β' -nitro-*N*-methyl- α -pyridone, m. 172°, identical with the product obtained by direct nitration of *N*-methyl- α -pyridone. Together with VII is obtained a small amt. of an isomer (VIII), m. 60°, also formed as chief product in the nitration of III, stable towards alkalis in the cold or on gentle warming but with boiling 10% alkalis regenerates III. Whether VII and VIII are *cis-trans* isomers or whether VIII is a structural isomer (IX) is left an open question for the present. Nitration of α , β -C₅H₃N(NH₂)NO₂ in cold concd. H₂SO₄ yields the nitramine C₅H₃N(NHNO₂)NO₂ (X) which with Me₂SO₄ yields a yellow compd (XI), m. 209°, as sensitive to HO ions as the β' -isomer (VII), decomp. into N₂O and *N*-methyl- β -nitro- α -pyridone, m. 176°. With Me₂SO₄ α , β -C₅H₃N(NH₂)NO₂ gives a small amt. of a compd., m. 70 2°. IV, greenish yellow, m. 205-7°. *Picrate* of III, m. 200-1° X, yellowish, m. 137° (decompn.).

C. A. R.

The δ -pyrindigo synthesis. EDUARD SUCHARDA. *Ber.* 58B, 1724-7(1925); cf. *C. A.* 19, 72; Chichibabin, *C. A.* 19, 1275.— β -Aminopicolinic acid (52 g.) with ClCH₂CO₂H and K₂CO₃ in H₂O on the H₂O bath gives 30 g. δ - or [*N*-pyridyl-3-glycine]-2-carboxylic acid, C₈H₅N(CO₂H)NHCH₂CO₂H, m. 245° (decompn.), can be recrystd from dil. acids; 5 g. heated in molten KOH at 260-5°, then cooled in illuminating gas, dissolved in H₂O, filtered, acidified with HCl and satd. with air gives 0.85 g. δ -pyrindigo,

sublimes with decompn. at high temps., very difficultly sol. in org. solvents, easily in concd. H₂SO₄ with blue color, very easily oxidized by HNO₃, decompd. by concd. alkalis with formation of light yellow solns., acids repptg. the dye from fresh solns. but not after they have stood some hrs. in the air; SO₂, HI and even HCl reduce it to the leuco compd.; reduction of the alk. solns. produces a deep-seated change. *Leuco- δ -pyrindigo-HCl*, brick-red, does not m. 360°, is oxidized to the dye at higher temps., dissolves to the extent of 3.68 parts in 100 of H₂O with red-brown color, air oxidizing the soln. to the dye; wool is dyed brown, turning blue after some days. *Leuco- δ -pyrindigo*, green-yellow powder, easily oxidized to the dye in the air, especially if moist or in the presence of dil. alkalis, forms quite stable salts with HCl and H₂SO₄ and red-violet salts with alkalis, concd. alkalis producing deep-seated decompn.; *tetra-Ac deriv.*, gradually

becomes brown in the air, is easily hydrolyzed by boiling acids or alkalis; the AcOH soln. becomes intensely red on short boiling but is decolorized by Ac_2O . C. A. R.

Arsonophenylcinchoninic acid (arsonocinchophen) and derivatives. II. H. O. CALVERY, C. R. NOLLER AND ROGER ADAMS. *J. Am. Chem. Soc.* **47**, 3058–60 (1925); cf. C. A. **19**, 1255.—5-Nitroisatin, m. $254-5^\circ$ (cor.) and BzMe with KOH give 20% of 2-phenyl-4-carboxy-6-nitroquinoline (nitrocinchophen), bright yellow, decomps. about $350-5^\circ$; reduction with SnCl_2 in HCl gives 97% of the 6-amino deriv., bright orange, shrinks 240° , m. $259-60^\circ$ (decompn.). Diazotized and treated with As_2O_3 in KOH- Na_2CO_3 there results 2-phenyl-4-carboxy-6-arsonoquinoline, does not m. 360° . 2,2'-Phenyl-4,4'-carboxy-6,6'-arsenoquinoline, red, does not m. 300° . C. J. WEST

Dependence of rotatory power on chemical constitution. XXVII. The optical properties of alkyl *p*-toluenesulfonates. HENRY PHILLIPS. *J. Chem. Soc.* **127**, 2552–87 (1925); cf. C. A. **19**, 2331.—*Et dl-p-toluenesulfonate* (I), $b_{0.1}$ $99-104^\circ$, n_D^{25} 1.5309, d_4^{25} 1.114, $d_4^1 = 1.137-0.000935t$, γ (dynes/cm.) 38.48, 37.03, 35.23 at 18° , 32° and 49.5° . *Bu ester*, $b_{0.1}$ $90-5^\circ$, n_D^{25} 1.5195, d_4^{25} 1.066. *l-β-Octanol* with $\alpha_D^{21} -8.10^\circ$ gives a *l-β-octyl ester*, $b_{0.1}$ $125-8^\circ$, n_D^{25} 1.5065, $\alpha_D^{22} -22.16^\circ$ (in an Et_2O soln. with K_2CO_3); its rotatory power became $\alpha_D^{19} -8.28^\circ$ after 360 hrs., $\alpha_D^{21} -8.21^\circ$ after 792 hrs., $\alpha_D^{18} -8.01^\circ$ after 1608 hrs. and $\alpha_D^{20} -7.88^\circ$, $\alpha_{5461}^{20} -9.75^\circ$, $\alpha_{4359}^{20} -17.08^\circ$ after 2376 hrs., n_D^{20} 1.5053. The rate of reaction with AcOH was followed by the decrease in optical activity. The ester (II) prepd. with $\text{C}_6\text{H}_5\text{N}$ had n_D^{25} 1.5052, $\alpha_{5893}^{25} -5.98^\circ$, $\alpha_{5461}^{25} -7.56^\circ$, $\alpha_{4359}^{25} -12.16^\circ$ changing after 1433 hrs. to -16.04° , -19.66° and -35.20° , resp. The ester, after 1435 hrs., dissolved in Et_2O and washed with K_2CO_3 , $b_{0.1}$ $105-10^\circ$, n_D^{25} 1.5044, $\alpha_{5893}^{25} -11.64^\circ$, $\alpha_{5461}^{25} -14.03^\circ$, $\alpha_{4359}^{25} -25.68^\circ$. The ester (III) prepd. by heating I with *l-β-octanol*, $b_{0.1}$ 122.4° , n_D^{19} 1.5078, $\alpha_D^{14} -21.16^\circ$, which, after 1511 hrs., showed $\alpha_{5893}^{25} -16.08^\circ$, $\alpha_{5461}^{25} -19.62^\circ$, $\alpha_{4359}^{25} -35.14^\circ$. The recovered ester had n_D^{25} 1.5005, d_4^{25} 1.000, $\alpha_{5893}^{25} -13.52^\circ$, $\alpha_{5461}^{25} -16.25^\circ$, $\alpha_{4359}^{25} -30.09^\circ$. The mutarotation in C_6H_6 was also studied. A series of fractionations of II finally gave a *l-β-octyl l + dl-p-toluenesulfonate*, n_D^{25} 1.5051, d_4^{25} 1.010, $\alpha_{5893}^{25} -29.45^\circ$, $\alpha_{5461}^{25} -35.13^\circ$, $\alpha_{4359}^{25} -66.39^\circ$; at 25.15° , its rotation was const. for at least 762 hrs., but after 860 hrs. it had n_D^{25} 1.5039, $\alpha_{5893}^{25} -8.46^\circ$, $\alpha_{5461}^{25} -9.95^\circ$ and $\alpha_{4359}^{25} -18.04^\circ$. III, on distn., finally gave a mixt. of the *d + dl ester*, n_D^{25} 1.5055, d_4^{25} 1.005, α_{5893}^{25} 6.67° , α_{5461}^{25} 7.61° , α_{4359}^{25} 15.71° ; after 1443 hrs. these values had changed to -15.84° , -19.12° and -34.12° , n_D^{25} 1.5035. These data indicate that some interconversion of the *d*- and *dl*-forms takes place. On heating I menthol and I at 60° and 15 mm. for 48 hrs., there results a *l-menthol ester*, m. 98.100° , $[\alpha]_{5893}^{17} -177.2^\circ$, $[\alpha]_{5461}^{17} -213.0^\circ$, $[\alpha]_{4359}^{17} -387.4^\circ$ (*c* 2.483 in Me_2CO); after 3 crystals, from dil. Me_2CO , it m. $108-9^\circ$, and shows $[\alpha]_{5461}^{17} -239.9^\circ$, $[\alpha]_{4359}^{17} -433.8^\circ$ (*c* 2.609 in Me_2CO) and is considered pure *l-menthyl l-ester*. Oxidation gives *l-menthyl p-toluenesulfonate*. There is evidence that the *l*-rotatory power of the ester increases considerably on standing. If the reaction is carried out in $\text{C}_5\text{H}_5\text{N}$, there results the solid *l + dl ester* and the liquid *d + dl ester*, decomps. 190° at 0.05 mm., $[\alpha]_{5461}^{17}$ 35.04° , $[\alpha]_{4359}^{17}$ 76.38° (*c* 2.782 in Me_2CO). On standing for 91 days the ester becomes cryst. (*l + dl ester*). *l-β-Octanol* and I, heated at 60° and 16 mm. and then at 40° at a lower pressure and the product carefully fractionated, finally gave a *l + dl-I*, $b_{0.1}$ $74-6^\circ$, n_D^{25} 1.5309, $\alpha_{5461}^{25} -3.36^\circ$, which could not be sepd. into fractions with different rotatory powers. On oxidation the activity is lost. The fractions of the *l-β-octyl ester* formed during the above reaction differed considerably in rotatory power; the lowest value observed was $\alpha_{5461}^{25} -34.20^\circ$. The *butyl l + dl-ester*, obtained similarly, $b_{0.1}$ $80-94^\circ$, n_D^{25} 1.5175, $\alpha_{5461}^{25} -4.59^\circ$. After standing 4 days, some racemization occurred during a redistn. Various expts. are also reported in which impure *Et d + dl-ester* was prepd. *dl-p-MeC}_6\text{H}_4\text{SOCl}, treated with 0.5 equiv. of *l-β-octanol* in $\text{C}_6\text{H}_5\text{N}$ and then with PhNH_2 , gives a *l-p-toluenesulfonanilide*, m. 134° , $[\alpha]_{5461}^{17} -1.1^\circ$ (*c* 5.0 in CHCl_3) and -0.65° (*c* 4.669 in $\text{C}_6\text{H}_5\text{N}$). A similar product was obtained with *l*-menthol. The *Et l + dl-ester* was converted into the *Bu d + dl-ester* by warming with BuOH for 18 hrs. at 15 mm. *l*-Menthyl *p*-toluenesulfonate, warmed with glacial AcOH on a H_2O bath for 12 hrs., gave a mixt. of *l*-menthol and *d*-neomenthol. AcONH_4 at 110° for 96 hrs. also causes this transformation. *l-β-Octyl p-toluenesulfonate* and AcOK in EtOH give *d-β-octyl acetate*, while BzOK gives *l-β-octyl Et ether* and benzoate. *d-β-Octyl ethyl ether*, b_{17} $73-4^\circ$, d_4^{20} 0.7838, n_D^{21}*

1.4095, n_{D461}^{21} 1.4105, $\alpha_{D893}^{21.5}$ 15.38°, $\alpha_{D461}^{21.5}$ 18.08°, $\alpha_{D359}^{21.5}$ 33.36°. The original should be consulted for the interesting theoretical discussion.

C. J. WEST

A new pyridanthrone synthesis. REINHARD SEKA. *Ber.* 58B, 1778-83(1925).—*m*-[Cinnamylamino]benzoic acid (I), from $H_2NC_6H_4CO_2H$ and $PhCH:CHCOCl$ in boiling C_6H_6 (yield, 75%), or from $H_2NC_6H_4CO_2H$ and $PhCH:CHCO_2Et$ in sealed tubes at 120°, m 242°; *N*-1c deriv of I with concd H_2SO_4 at 80-90° gives 17-20% 1(N).9-pyridanthrone-(2') (II), yellow, m 406-8°. A com sample of II (*Ger pat* 216,597), after sublimation *in vacuo* and crystn from $PhNO_2$, yielded a product identical with the above *m*-[Cinnamylamino]anistic acid, m 267-8°, similarly gives, but in very small amt. only, the 2-MeO deriv of II, yellow, m 326°, sol in concd. H_2SO_4 with vivid yellow-green fluorescence. *m*-[Cinnamylamino] *p*-toluic acid, m 279°, gives 25-30% of the 2-Me deriv of I (*Ger. pat.* 212,201), yellow, begins to darken 330°, carbonizes 356-9°.

C. A. R.

Methylation of diketopiperazines and piperazines. EMIL ABDERHALDEN AND RICHARD HAAS. *Z. physiol. Chem.* 148, 245-53(1925).—Preliminary to a study of the possibility of increasing the yield of diketopiperazines by methylation of the protein before hydrolysis, a no. of methylated piperazines were prepd. *N,N'*-Dimethylpiperazine-2/III seps in crystals when piperazine in MeOH is refluxed with MeI. *N,N'*-Tetramethylpiperazinium diiodide, decomps 278°, results from further treatment with MeI. Both of these form addn. products with I. Methylation of piperazine by Me_2SO_4 and treatment with HCl and $HgCl_2$ gave a double salt of the compn $C_4H_{10}N_2Cl_2 \cdot 2HgCl_2$. Treatment of this with H₂S gave *N,N'*-tetramethylpiperazinium dichloride, decomps 276°. Sulfate, m 230°, by treatment of the preceding with Ag_2SO_4 . Hydroxide, decomps 175°, was obtained from the sulfate and $Ba(OH)_2$. Methylation of glycine anhydride with Me_2SO_4 gave sarcosine anhydride, and reduction of the latter with Na and EtOH gave *N,N'*-dimethylpiperazine 2/HCl after distg. and acidifying with HCl.

A. W. DOX

Preparation of methylated piperazines. EMIL ABDERHALDEN AND RICHARD HAAS. *Z. physiol. Chem.* 149, 94-9(1925).—3,5-Dimethylpiperazine adds MeI in the same manner as piperazine (cf. preceding abstr.). 1,2,4,5-Tetramethylpiperazine 2/III, (I), m. 257° (decompn.), was prepd. in 75% yield by refluxing 2,5-dimethylpiperazine with MeI. Mono-III salt, m 178° (decompn.), by treating I with NaOH and extg. with $CHCl_3$. The free base, sirup with slight tendency to crystallize, was obtained from I by treatment with Al_2SO_4 and the exact equiv. of $Ba(OH)_2$. 1,1,2,4,5-Hexamethylpiperazinium diiodide (II), m 250°, in 70% yield from dimethylpiperazine and excess of MeI. Hydroxide, m 224°, by treatment of II with Ag_2SO_4 and $Ba(OH)_2$, extn. with EtOH and pptn. by petroleum ether. Dichloride + $HgCl_2$ (III), m 250° (decompn.), in 79% yield by methylation of 2,5-dimethylpiperazine with Me_2SO_4 , addn. of HCl and pptn. with $HgCl_2$. Dichloride decomps 300°, by treatment of II with H₂S. Both I and II form addn. products with I and are pptd. by $KBiF_4$.

A. W. DOX

Sulfonation of 4-chlorophenol. J. M. GAUNTLETT AND SAMUEL SMILES. *J. Chem. Soc.* 127, 2745-6(1925).—Na 4-chloroanisole 2-sulfonate, prisms with 2H₂O, lost at 120°. 4-Chloroanisole-2-sulfonyl chloride, m 104°, the amide, m 151°. Aq. Na_2SO_4 and the chloride give 4-chloroanisole 2-sulfonic acid, m 116°; with Me_2SO_4 and NaOH this gives 4-chloroanisole 2-Me sulfonic, m 91°, while with dil. HI it gives 4-chloroanisole 2-disulfoxide, m 124.5°. 4-Chloroanisole 2-mercaptan, m 42°, volatile with steam. 4-Chloroanisole 2-disulfide, m 105°. The product obtained from the methylation of the sulfonation product of 4-ClC₆H₄OH is identical with that from 5,2-H₂N(MeO)C₆H₃SO₃H.

C. J. WEST

Strychnos alkaloids. XLV. Oxidation experiments with Hanssen's acid. HERMANN LEUCHS (in part with KARL TAUBE). *Ber.* 58B, 1729-32(1925); cf. C. A. 19, 522.—The H acid, $C_{19}H_{22}O_6N_2$ (I), in 2 mols. NaOH with 3% H_2O_2 gives the amine oxide, $C_{19}H_{22}O_7N_2$, isolated as the HBr salt (0.9 g. from 1 g. I), needles with 2 H₂O, gives with $AgNO_3$ only a turbidity, a ppt. being formed only on boiling or adding an acid. Slowly treated in H₂O at 0° with O_3 , I gives 15-20% of the nitrate of I (HNO_3) having been produced from the N in the O during the ozonization) and 30% of unchanged I; no definite compd. could be isolated from the remaining 50% of oxidation products. With 6 atoms Br in H₂O at 100° in sealed tubes, however, I HBr gives, through an amorphous ppt. (perbromide) which slowly re-dissolves, 35% of a compd. $C_{19}H_{22}O_8N_2 \cdot HBr \cdot 3H_2O$, which immediately ppts. AgBr with $AgNO_3$, dissolves in 6-8 parts hot N HBr (sometimes, however, it seps. in thin leaflets which are sol. only in about 30 parts HBr); nitrate, dissolves in about 10 parts hot H₂O or 40-50 parts hot N HNO₃; free acid, obtained in 40% yield from the HBr salt with NaOH, prismatic columns with 1 H₂O;

oxime-HCl, $C_{19}H_{23}O_3N_3 \cdot HCl$, prisms and rectangular tablets with 9.5–9.6% H_2O , sol. in less than 20 parts hot H_2O . C. A. R.

Formation of phenolates with the aid of metals. F. ZETZSCH, H. SILBERMANN AND G. VIELI. *Helvetica Chim. Acta* **8**, 596–602 (1925).—Only Al (*J. Am. Chem. Soc.* **28**, 608–17 (1906)) and the alkali metals appear to have been previously used. With finely divided Mg and 8-HOC₆H₄N (I) in dry C_6H_6 no phenolate is formed, but when increasing small amts. H_2O are added in the form of 96% alc., a max. of 74% of the theory is obtained at a H_2O concn. of 0.1%, the yield falling off rapidly beyond this point. *o*-HOC₆H₄CHO (II) in alc. of various concns. gives a max. yield of 77% Mg salt in 72% alc. The most reactive phenols tested were I and II and 2,3-HO(MeO)C₆H₃CHO (III). *o*-Hydroxychalcones and Me, Et and Ph salicylates did not react. The anils of II and III and *o*-HOC₆H₄CH NNIIPh failed to give Mg and Zn salts, but reacted with Co and Cu. Many of the salts could not be sepd. from the metal powder on acct. of their insol. but in the case of Mg *8-hydroxyquinolate* (IV), if $PhNO_2$ was used as diluent and the Mg and 72% alc. were added in small amts. (method A), the salt was finely divided enough to run through a "Barytfilter" and could then be pptd. by Et_2O ; greenish yellow, mobile powder, turns lemon-yellow 100°, decomps. 200°, insol. in the usual solvents; Zn salt, from Zn powder and I in 72% alc. for 5 days or at the b. p. 6–8 hrs.; purified by extn. with boiling C_6H_{10} (method B); light yellow crystals turning darker above 100°, m. above 260°, yield, 80%. Mg salts of: *salicylaldehyde* (method A), like IV; *2-aceto-1-naphthal* (method B), greenish yellow needles; *1-hydroxyxanthone* (A), yellow needles. Co salts of: *8-Hydroxyquinoline* (B), yellow needles; *salicylaldehyde* (B), yellow needles. Cu salts of: *8-Hydroxyquinoline* (B), greenish brown crystals, *salicylaldehyde* (B), brownish yellow needles, *salicylideneaniline* (B), brown needles, m. 222–6° (cf. Schiff, *Ann.* **150**, 197 (1869)). *Salicylaldehyde*, Zn salt (B), yellow needles from $CHCl_3$. Fe^{++} disalicylate (V) from the acid and Fe powder, boiled in 2% alc. for 1 hr., filtered in a H_2 or N_2 atm., and concd. dry at 140°, yellow, turning green on the surface when exposed to air. Fe^{++} salts of: *8-Hydroxyquinoline*, from I in alc., N NaOH, and V in H_2O , flesh colored to brown hexagons of angle 120°, m. and discolors 120°; *salicylaldehyde*, blue-violet, *o*-vanillin, green, sinters, then turns red and m. 156–8°. The Fe^{++} salts are obtained impure unless all manipulations are rapidly carried out. IV and *p*-O₂NC₆H₄COCl in $CHCl_3$ gave *p*-nitrobenzoyloxyquinoline, m. 171–5°; *p*-nitrobenzoylsalicylaldehyde, m. 123–4°; phenylhydrazone, orange, m. 210–1° (decompn.). A table is given showing the metals with which a no. of phenols react.

M. HEIDELBERGER

Constitution of pine wood lignin. V. PETER KLASON. *Ber.* **58B**, 1761–4 (1925); cf. C. A. **19**, 1851.—To det. the smallest quantity of SO_2 which can be present in a lignosulfonic acid, 43 g. very fine wood powder was extd. with petroleum ether and MeOH and cooked 8 days with nearly satd. H_2SO_4 at about 55°; it now gave 15 g. of a yellow β -C₁₀H₇NH₂ inner salt of the compn. $3C_{10}H_{10}O_3 + H_2SO_4 + C_{10}H_9N \cdot H_2O$, *i. e.*, it is apparently impossible to obtain a compd. with less than 1 mol. SO_2 to 3 of C₁₀H₁₀O₃ and the acid $3C_{10}H_{10}O_3 + H_2SO_4$, which is first formed in the sulfite cooking, must constitute the main part of the sulfonic acids of the waste liquor, although such liquors must also contain acids with more SO_2 . The lignosulfonic acids are not combined with carbohydrates; when the C₁₀H₇NH₂ salt is converted into the K salt with KOH, freed from C₁₀H₇NH₂ with Et_2O and inverted 5 hrs. on the H_2O bath with HCl, it gives no trace of Cu_2O with Fehling soln. By repeated treatment of the waste liquor with SO_2 and cooking at 100° and 120° the S content of the C₁₀H₇NH₂ salt can be raised to 8.31%; this salt, $C_{10}H_{10}O_3 + H_2SO_4 + C_{10}H_9N \cdot H_2O$, is apparently a deriv. of the simple (monomeric) coniferyl aldehyde; when pptd. in nearly neutral soln. it has the compn. $C_{10}H_{10}O_3 + H_2SO_4 + 2C_{10}H_9N \cdot H_2O$, *i. e.*, it is both an anil and an NH_4 salt. With a waste liquor contg. the acid $3C_{10}H_{10}O_3 + H_2SO_4$ pptn. in nearly neutral soln. gives a red salt $3C_{10}H_{10}O_3 + H_2SO_4 + 2C_{10}H_9N \cdot H_2O$. From a luke-warm, not too dil. soln. of β -C₁₀H₇NH₂ HCl shaken with paraldehyde and allowed to stand some days is obtained a yellow-brown cryst. salt $(AcH)_3 + 2C_{10}H_9N \cdot 2H_2O$, while metaldehyde, even on heating, is much more stable towards C₁₀H₇NH₂ HCl. Synthetic PhCH·CHCHO, especially if old, contains polymers; the monomer is dissolved away by shaking with satd. aq. SO_2 at room temp. and the polymers remaining are shaken hot in sealed vessels with aq. SO_2 ; there is thus obtained through the Ba salt an acid which in HCl with β -C₁₀H₇NH₂ HCl gives a yellow, apparently cryst. compd. $(PhCH \cdot CHCHO)_3 + H_2SO_4 + C_{10}H_9N \cdot H_2O$, m. around 160°. The Ba salt with aq. SO_2 at 110–5° does not add more SO_2 and at 130–5° decomps. into its components. Since α -lignosulfonic acid thus corresponds, point for point, with the sulfonic acid of cinnamparaldehyde, it may be assumed provisionally that α -lignin is coniferyl paraldehyde. C. A. R.

yielding with $\text{SnCl}_2 \cdot \text{HCl}$ 78.5% of 2,2'-dimethyl-5,5'-diaminobiphenyl, b_{13} 225–8°, m. 96–8°; *di-HCl salt*. The diamine (3 g.), when diazotized in H_2SO_4 and heated on the H_2O bath, gives 2,2'-*di-p-cresol* (0.4 g. product purified by sublimation under 13 mm.), m. 229°, gives no color with aq. or alc. FeCl_3 or with PbO_2 in boiling C_6H_6 , is not volatile with steam, dissolves in 98% H_2SO_4 without color. Unsuccessful attempts were made to prep. the dicresol from *o*-iodo-*p*-cresol which was obtained in 17.5% yield from the *o*- NH_2 compd. and m. 63–4°; its *benzoate*, m. 53°. *p*- $\text{MeC}_6\text{H}_4\text{OCH}_2\text{C}_6\text{H}_4\text{NH}_2(p)$ on diazotization in $\text{AcOH} \cdot \text{H}_2\text{SO}_4$ gives *p*-cresol *p*-acetoxymethyl ether (62.5% crude product), m. 98°, decompd. on even cautious hydrolysis at 0° with aq. or alc. alkalis or NH_4OH into *p*-cresol (and *p*- $\text{HOC}_6\text{H}_4\text{CH}_2\text{OH}^?$), no further efforts were made to isolate the free $\text{MeC}_6\text{H}_4\text{OCH}_2\text{C}_6\text{H}_4\text{OH}$, as its instability sufficed to show that it was not identical with I or III. *Di-[\omega-chloro-p-cresyl] carbonate*, from $\text{CO}(\text{OC}_6\text{H}_4\text{Me})_2$ and Cl at 120–30° (yield, 39%), m. 95°; 25 g. refluxed with *p*- $\text{MeC}_6\text{H}_4\text{ONa}$ gives 11 g. 3-methyl 6,6'-*di-hydroxydiphenylmethane*, b_{12} 227–35°, m. 135.5°, gives a blue color with aq. FeCl_3 , dissolves in H_2SO_4 without color; *diacetate*, m. 86°; *di-Me ether*, from the phenol in KOH with Me_2SO_4 , m. 74°, also obtained by reduction by the Clemmensen method of 3,6-Me(MeO) $\text{C}_6\text{H}_3\text{COC}_6\text{H}_4\text{OMe}(4)$, prepd. from *p*- $\text{MeOC}_6\text{H}_4\text{COCl}$ and *p*- $\text{MeC}_6\text{H}_4\text{OMe}$.
C A R

Formation of desoxybiliaric acid from bilianic acid, and of desoxycholic and of isodesoxybiliaric acids from isobiliaric and desoxycholic acid. RICHIO KARASAWA. *J. Biochem. (Japan)* 5, 105–12(1925).—To 1 g. of pure isobiliaric acid in 75 cc. 7% KOH , is added in the course of 30 min. 2 cc. Br_2 . The clear soln. is cooled on the water bath to about 30 cc. (it should be acid to litmus), mixed with an equal vol. of H_2O , left overnight, then filtered and the residue washed with ice cold H_2O . The filtrate and wash water are carefully acidified to Congo red with dil. H_2SO_4 until a yellow ppt. is formed. The filtrate from this is again acidified and left for several days. The pptd. substance is dissolved in dil. alc. and decolorized with charcoal. This is then boiled with $\text{Ba}(\text{OH})_2$ and the Ba salt filtered off while hot and washed with hot water. The ppt. is now evapd. on the water bath with a Na_2CO_3 soln. to complete dryness and extd. with H_2O . On acidifying the H_2O ext. with dil. HCl a Br free substance is obtained. The substance which remains insol. in hot water is crystd. from dil. alc. It is easily sol. in acetone and glacial AcOH . Dried *in vacuo* at 110–15°, the acid m. 247–8°. The analyses show it to be isodesoxybiliaric acid. When 2 g. pure bilianic acid in 150 cc. 7% KOH is treated with 4 cc. Br_2 (the remaining procedure being the same as before) there is obtained desoxybiliaric acid, m. 294.5°. Similarly 2 g. of desoxycholic acid, in 150 cc. 7% KOH with 4 cc. Br_2 as above gives a Ba salt, part of which is sol. in hot water and yields desoxybiliaric acid, whereas the fraction insol. in the hot water gives isodesoxybiliaric acid.
S MORGULIS

Scymnol-sulfuric acid. I. SHU OIKAWA. *J. Biochem. (Japan)* 5, 63–70(1925).—The bile from sharks is freed of lipins with ether and CHCl_3 , and is then thoroughly extd. with alc. The combined alc. extracts are evapd. and the residue is treated in H_2O with $\text{Pb}(\text{OAc})_2$ and NH_4OH . The pptd. Pb salts are converted into alkali salts by heating on the water bath with Na_2CO_3 , freed from the carbonates by extn. with alc. and pptd. with ether. The α -scymnol-sulfuric acid is isolated from this mixt. of bile salts as follows. To the Na salts in H_2O is added an equal vol. 40% KOH . On standing in the ice box a ppt. is formed which is removed by centrifuging. The ppt. is redissolved in H_2O satd. with CO_2 and the scymnol-sulfuric acid is pptd. with ether from the H_2O soln. treated with alc. to remove carbonates. After repeated purification by ether pptn. of the alc. soln. the substance was obtained (Na salt) as snow-white needles, sol. in H_2O and alc. but insol. in ether or CHCl_3 . It has a sweetish-bitter taste and gives the Pettenkofer bile acid reaction. The scymnol-sulfuric acid was hydrolyzed with $\text{Ba}(\text{OH})_2$, boiling under a reflux condenser for 30 hrs. when on cooling the scymnol sep'd. out as a cryst. ppt. This was dissolved in alc. and dild. with H_2O until the soln. turned turbid when it was placed in the ice chest. The α -scymnol, $\text{C}_{27}\text{H}_{48}\text{O}_6$, sep'd. rated as needles, with 2 H_2O , having a sweetish-bitter taste, m. 108°, $[\alpha]_{\text{D}}^{20}$ 38.2° (95% alc.), gives a violet soln. in 25% HCl . The O seems to be entirely in the form of OH groups. Its oxidation product, $\text{C}_{27}\text{H}_{48}\text{O}_8$, m. 208°, is readily sol. in Me and Et alc., acetone, CHCl_3 and glacial AcOH , but not readily sol. in ether. In alc. the soln. reacts acid and has $[\alpha]_{\text{D}}^{20}$ 51.7°. S. MORGULIS

Condensation of guaiacol with substituted benzoic acids. H. MANIWA. *J. Pharm. Soc. Japan* No. 515, 39–49(1925).—In order to study the method of phyllo-dulcin synthesis, the condensation of guaiacol with various substituted benzoic acids was attempted. Friedel-Craft's synthesis with 3-nitro-*o*-toluyl chloride and benzoyl-

guaiacol was not successful. Claisen and Schädwell's method, using 3-methoxytoluyl chloride and benzoylguaiacol in the presence of AlCl_3 gave crystals, 2,6-Me(MeO)- $\text{C}_6\text{H}_3\text{COC}_6\text{H}_3(\text{OMe})\text{OH}$ (3,4) (m. 97°), but detailed studies on this compd. could not be continued on account of the lack of material. When *o*-MeC₆H₄COCl is condensed with guaiacol carbonate in the presence of ZnCl_2 at 120° , a cryst. compd. MeC₆H₄COC₆H₃(OMe)OCOC₆H₃(OMe)COC₆H₄Me is obtained and on sapon. gives toluoguaiacol, MeC₆H₄COC₆H₃(OMe)OH, m. 112° , its acetate, m. $96-7^\circ$, benzoate, m. 98° , methyl ether, m. $72-3^\circ$, Et ether, m. $107-8^\circ$, and oxime, m. $164-6^\circ$. On heating with HI, toluoguaiacol gives 3,4-(HO)₂C₆H₃COC₆H₄Me, m. $105-6^\circ$, gives with FeCl_3 a green color, that becomes red with dil. alkali. S T

Formation of safroegenol and isosafroegenol (from safrol and isosafrol). K. KAFUKU. *J. Pharm. Soc. Japan* No 521, 609-24 (1925).—The purified safrol had n_D^{20} 1.5255, d_4^{20} 1.0960, b_6 $101-5^\circ$, b_{760} $231.5-2^\circ$, $[\alpha]_D$ 0 and m. $10-1^\circ$. Isosafrol was prepd. by refluxing pure safrol with alk. alc. and purified. It b_6 $111-2^\circ$, d_4^{15} 1.1196, n_D^{20} 1.5744. Hydrosafrol was prepd. by catalytic reduction with Pt black or Ni. The CH_2O rings of these compds were broken by the action of specially prepd. MeMgI for 5-6 hrs. at 80° ; and by subsequent steam distn., safroegenol, isosafroegenol and hydrosafroegenol were obtained. The safroegenol thus prepd. was identified as 3,4-HO(EtO)C₆H₃CH₂CH₂CH₃, which can be converted into isosafroegenol by a prolonged treatment with hot alk. soln. Its phenylurethan, m. $57.5-9.0^\circ$. The isosafroegenol is 3,4-HO(EtO)C₆H₃CH₂CHMe, m. 86° , its acetate, m. 67° , benzoate 59° , Me ether 63° and phenylurethan 123° . The hydrosafroegenol, m. 42.5° and is 3,4-HO(EtO)C₆H₃Pr, which can be obtained from safroegenol by catalytic reduction or by action of metallic Na and alc. on isosafroegenol. The special MeMgI was prepd. by cong. the ordinary Grignard's reagents to an almost sirupy consistency by removal of all Et₂O. The detailed method of identification of these products and their chem. and phys. characteristics are given in detail. S T

2-Amino-3-methoxybenzaldehyde and several of its derivatives. J. TRÖGER AND E. DUNKER. *J. prakt. Chem.* 111, 207-16 (1925).—2-Amino-3-methoxybenzaldehyde, oily, is obtained in 84% yield by reducing the NO₂ deriv. with FeSO_4 in a soln. of Na₂CO₃ and NaHSO₃; it is not volatile with steam, possesses basic properties, though cryst. salts could not be prepd.; oxime, m. 142° ; semicarbazone, yellow, m. 223° ; phenylhydrazone, m. 139° . In EtOH, it condenses with AcCH₂CO₂Et to give Et *o*-methoxyquin-aldine- β -carboxylate, crystg. with 1 H₂O, m. $76-9^\circ$ or, anhyd., m. $102-5^\circ$ (chloroplatinate, yellow needles). The free acid cryst. with 3 H₂O and m. 126° , Ag salt, amorphous, HCl salt; chloroplatinate, brownish red needles. The aldehyde and AcCH₂CO₂H at 160° give *o*-methoxy- β -acetylcarbostyril, canary-yellow, m. 183° (phenylhydrazone, orange-yellow, m. 119°). C J. WEST

Influence of the position of the NO₂ and NH₂ groups upon the reactivity of the aldehyde group in nitro and amino derivatives of *m*-hydroxybenzaldehyde and *m*-methoxybenzaldehyde. J. TRÖGER AND H. FROMM. *J. prakt. Chem.* 111, 217-39 (1925).—4,3-O₂N(HO)C₆H₃CHO condenses readily with arylsulfonacetonitriles; the following α -sulfon- β -3-hydroxy-4-nitrophenylacrylonitriles were prepd. benzene, light yellow, m. $155-6^\circ$; *p*-toluene, yellow, m. 184° ; *p*-chlorobenzene, light yellow, m. 170° , *p*-bromobenzene, egg-yellow, m. $182-3^\circ$; β -naphthalene, egg-yellow, m. 174° ; *o*-anisole, yellow, m. 187° (Ac deriv., light yellow, m. $156-7^\circ$); *p*-phenetole, Au-yellow, m. 188° . Condensation does not proceed as readily with 6,3-O₂NC₆H₄(OH)CHO and the products are not easily isolated; the following α -sulfon- β -3-hydroxy-6-nitrophenylacrylonitriles were prepd.: *p*-toluene, m. $115-6^\circ$; *p*-chlorobenzene, oily, analyzed as the Ac deriv., m. $130-1^\circ$; *o*-anisole, m. $142-3^\circ$. Similar results were obtained with the Me ethers of these aldehydes. α -*p*-Toluenesulfon- β -3-methoxy-4-nitrophenylacrylonitrile, light yellow, m. 188° ; *p*-chlorobenzene deriv., yellow, m. 206° ; the *p*-Br deriv. was also prepd. 6-Amino-3-methoxybenzaldehyde, analyzed as the HCl salt, and as the phenylhydrazone, m. $179-80^\circ$; the free aldehyde could not be isolated as it appears to polymerize, giving an EtOH- and Et₂O-insol. product. The aldehyde in alc. and *p*-ClC₆H₄SO₂CH₂CN give α -amino- β -*p*-chlorobenzenesulfon-*p*-methoxyquinaldine, egg-yellow, m. $181-2^\circ$, shows a strong green fluorescence in EtOH. 2,3-O₂NC₆H₄(OMe)CHO and *p*-MeC₆H₄SO₂CH₂CN give α -*p*-toluenesulfon- β -3-methoxy-2-nitrophenylacrylonitrile, yellow, m. 209° ; α -*p*-chlorobenzene deriv., yellowish, m. 202° ; α -*p*-bromobenzene deriv., Au-yellow, m. 215° ; α -*o*-anisole deriv., pale yellow, m. 193° . α -Amino- β -benzenesulfon-*o*-methoxyquinoline, canary-yellow, m. $243-4^\circ$; the β -*p*-chlorobenzene deriv., orange, m. 266° ; the β -*p*-bromobenzene deriv., canary-yellow, m. 281° ; the β -*p*-toluene deriv., orange, m. $256-7^\circ$; the β -*o*-anisole deriv., brownish, m. 260° ; the β -*p*-phenetole deriv., m. $272-3^\circ$.

While the 2,3-O₂NC₆H₄(OMe)CHO requires 1–2 hrs for the completion of the reaction, the 2-NH₂ deriv. requires only a few min.

C. J. WEST

Metallic compounds of 1,3-diketones. VI. The action of tin tetrachloride and zirconium tetrachloride upon 1,3-diketones. WALTHER DULTHEY. *J. prakt. Chem.* **111**, 147–52 (1925); cf. *Ann.* **344**, 300 (1905).—BzCH₂Ac (I) and ZrCl₄ in abs. Et₂O give the *compd.* (BzAcCH)₂ZrCl₂, yellow, m. 232–4°; in boiling C₆H₆ an excess of I gives the *compd.* (BzAcCH)₃ZrCl, m. 260°. SnCl₄ and I in CHCl₃ give the *compd.* (BzAcCH)₂SnCl₂, pale yellow, m. 220°. SbCl₅ gives the *compd.* (BzAcCH)₂SbCl₄, orange, m. 184°. (Bz₂CH)₂SbCl₄, orange, m. 232–4°; the *compd.* does not show salt-like properties. The *compd.* (Bz₂CH)₂SnCl₄, m. 243–4°, is so stable that it can be recrystd. from EtOH. A *compd.* with more than 2 BzCH₂ residues could not be prepd.

C. J. WEST

Dibenzalacetone and triphenylmethane. XII. Dimethylacetal and chloromethylate of *p,p*-dimethoxybenzalacetophenone. FRITZ STRAUS and WALTHER HEYN. *Ann.* **445**, 92–110 (1925); cf. *C. A.* **19**, 1410. MeOC₆H₄CCl₂CHCHClC₆H₄OMe, best prepd from the ketone and (COCl)₂, gives with 2% MeONa in C₆H₆, 80% of *p,p*-dimethoxybenzalacetophenone *di-Me acetal* (I), b_{0.8–0.9} 228–30°, light yellow oil, satd. towards alk. KMnO₄, very sensitive towards acids, catalytic reduction gives *p,p*-dimethoxybenzalacetophenone *di-Me acetal*, b_{0.6–0.7} 217–8°, d₂₀²⁰ 1.098, n_D²¹ 1.54139. I in CS₂ with CS₂ satd. with HCl gives a carmine-red HCl salt with steel blue luster, which is very sensitive towards moisture, immediately giving the ketone, m. 101.5°. With MeONa it regenerates I; heated in a stream of H₂, there results the ketone, MeCl and HCl. The salt gives a dimorphous (red and brown) HgCl₂ salt, C₁₇H₁₆O₃CH₃Cl HgCl₂. MeOC₆H₄COCH₂CHC₆H₄OMe is turned to a red powder by passing HCl over it; in liquid SO₂ the HCl salt ppts., dark red; the HBr salt, red, appears to be somewhat more stable the HCl HgCl₂ salt is cinnabar-red. MeOC₆H₄CCl₂CH(OMe)C₆H₄OMe decomps. into the ketone and MeCl; under the influence of a trace of HCl, the chloride is transformed into (MeOC₆H₄C(OMe)CHCHC₆H₄OMe)Cl, from which NaOMe gives the ketone, m. 102°. *p,p*-Dimethoxycinnamylidenacetophenone *di-Me acetal*, pale yellowish brown oil, b_{0.2–0.6} 241–3° (45% yield); the CS₂ soln. is colored violet by HCl and deposits the bluish black HCl salt. Conc'd. HCl gives *p,p*-dimethoxycinnamylidenacetophenone, m. 112.5–3°; conc'd. H₂SO₄ gives an orange soln.

C. J. WEST

Ester and sulfonate derivatives of anthranilic and methylantranilic acids. O. KELLER and G. SCHULZE. *Arch. Pharm.* **263**, 481–502 (1925).—In connection with a study of damascenine, the alkaloid of *Nigella damascena*, certain esters and SO₃H acid derivs. of anthranilic and methylantranilic acids were prepd. and characterized anew. Expts. with the esters showed their formation from low-mol. aliphatic alics. to be smooth, while those of higher mol. wt. and with side chains were obtained only with difficulty. The sepn. of the esters from unchanged acid was effected with Na₂CO₃ and Et₂O in the case of anthranilic acid, while methylantranilic acid was easily extd. from an alk. Na₂CO₃ soln. The ester HCl salts of both acids crystd. readily and were stable in a dry state. All the esters (HCl salts) examd. are hydrolyzed in H₂O, with sepn. of the free esters, in contrast with the behavior of damascenine-HCl (Me methoxymethylantranilate) and of damascenine-SHCl (methoxymethylantranilic acid). These HCl salts yield clear aq. solns. with no apparent hydrolysis, thus indicating in this connection the great influence of the OMe group. The esters described (Me, Et and Pr) of anthranilic, and (Me and Et) of methylantranilic acids are not saponif. either by cold or hot H₂O, or in HCl soln. Damascenine on the contrary suffers hydrolysis on recrystn., as also on the dry heating of its HCl salt. Expts. on the sulfonation of anthranilic acid lead to the conclusion that at present only the *m*- and *p*-sulfonates are known.

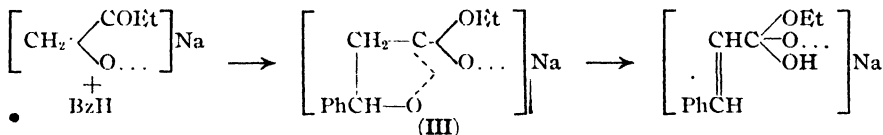

W. O. E.

Hydroxybenzal azides and indoxazenes. HANS LINDEMANN and ALBERT MÜLLHAUS. *Ann.* **446**, 1–13 (1925).—4-Hydroxy-3,5-dibromo-2,6-dimethylbenzal azide, m. 101° (decompn.), from the corresponding bromide and NaN₃; boiling with EtOH gives 3,5,2,6,4-Br₂Me₂(HO)C₆CHO; boiling AcOH gives the corresponding benzonitrile, m. 189° (*Ac deriv.*, m. 161°); sapon. with H₂SO₄ gives the corresponding acid amide, m. 270° (decompn.). 2-Hydroxy-3,5-dibromobenzal azide, m. about 70° (explodes on rapid heating); heating with C₆H₆ or AcOH gives 4,6-dibromoindoxazene, m. 141°, which is changed by heat or EtOH-NaOH into 3,5,2-Br₂(HO)C₆H₂CN, m. 174° (Auwers and Walker, *Ber.* **31**, 3042, give 167–8°), whose *Ac deriv.*, m. 97°. 3,5-Dibromo-4,6-dimethyl-2-hydroxybenzal azide, m. 64° (decompn.); 4,6-dibromo-3,5-dimethylindoxazene, m. 185°, giving 3,5-dibromo-4,6-dimethyl-2-hydroxybenzonitrile, m. 212° (*Ac deriv.*, m. 145°), saponif. by conc'd. H₂SO₄ to the corresponding acid amide, m. 267° (*Ac deriv.*, m. 137°).

C. J. WEST

Course of the reaction in Claisen's cinnamic ester synthesis. HELMUTH SCHEIB-

LER AND HERMANN FRIESE. *Ann.* **445**, 141-58(1925).—Since there is little difference in the yield of $\text{PhCH:CHCO}_2\text{Et}$ (I) and $\text{PhCH:CHCO}_2\text{H}$ (II) when BzH is added to a freshly prep'd. soln. of K and AcOEt , a soln. which has stood for 24 hrs. or when BzH and AcOEt in Et_2O are treated with K , the 1st phase of the reaction consists in the formation of an enolate, $\text{CH}_2\text{:C(OK)OEt}$, of AcOEt . Thus, 10 g. K powder and 22.5 g. AcOEt in 300 Et_2O with 13.3 g. BzH in 100 cc. Et_2O gave 32.9% II and 25% I; if the BzH is added after 42 hrs., there result 32.9% II and 28.2% I; if the 3 reactants are added simultaneously, there result 31.1% II and 29.5% I. With Na in place of K , the % yields of II and I under the 3 conditions above are: 35.6 and 13.6; 59.7 and 20.5; 54.8 and 18.2. The solid reaction product of Na and AcOEt (13.8 g.), mixed with 11.7 g. BzH , gives after 2 days, 7.3 g. II, 4.5 g. I and 2.5 g. unchanged BzH . BzH does not react with anhyd. $\text{AcCHNaCO}_2\text{Et}$. BzH (42.4 g.), 52.8 g. AcOEt and 9.2 g. Na , boiled until the Na had disappeared, the excess AcOEt boiled off and then twice evap'd. with AcOEt , gave about 90 g. of a resinous, brown, hygroscopic mass (III) which, decomp'd. with cold dil. H_2SO_4 , gave 82.4% II and 13.9% I. The use of 4 mols. BzH to 1 mol. EtONa did not improve the yield. III reacts with AcCl in Et_2O to give

II, I, AcOH and AcOEt . In C_6H_6 , 33 g. III and 12 g. AcCl give 8.4 g. II, 10.4 g. I and 10.4 g. resinous product. With PhCH_2I , 15.1 g. III in Et_2O gives 3 g. II, $\text{PhCH:CHCO}_2\text{CH}_2\text{Ph}$, PhCH_2OH and EtOH . AcOCH_2Ph , BzH and Na give 20.8% I and 73% $\text{PhCH:CHCO}_2\text{CH}_2\text{Ph}$. The intermediate condensation product reacts with EtBr to give II, $\text{PhCH:CHCO}_2\text{CH}_2\text{Ph}$, EtOH and PhCH_2OH . BzH , $\text{Me}_2\text{CHCO}_2\text{Et}$ and EtONa give 20.6% of α, α -dimethyl- β -phenylhydraerylic acid, m. 134° and 47.8% of its ester.

Relation between chemical constitution and pungency in acid amides. E. C. S. JONES and F. L. PYMAN. *J. Chem. Soc.* **127**, 2588-98(1925).—A no. of acylbenzylamides have been prep'd. by Nelson's (*C. A.* **14**, 547) or Einthorn's method (*Ann.* **343**, 207(1905)). It appears that the shape rather than the wt. of the side-chain is the important factor in the matter of pungency. The m. p. (cor.), yield and pungency are reported: Nonovanillylamide, $57-9^\circ$, 86%, 100; α -isopropylhexovanillylamide, $124-5^\circ$, 80%, 5; $\Delta\omega$ -undecenovanillylamide, $58-60^\circ$, 89%, >100; benzovanillylamide, $144-5^\circ$, 90%, 0.5; phenylacetovanillylamide, 112° , 80%, 0; β -phenylpropiovanillylamide, $80-3^\circ$, 88%, 40; γ -phenylbutyrovanillylamide, $93-5^\circ$, 85%, >40; δ -phenylvalerovanillylamide, 67° , 85%, >40; β -*p*-nitrophenylpropiovanillylamide, 119° , 80%, 20; cinnamovanillylamide, $146-7^\circ$, 85%, 0.5; α, β -dichloro- β -phenylpropiovanillylamide, $164-5^\circ$, 60%, 3; chloroacetovanillylamide, $119-22^\circ$, 76%, 3; dichloroacetovanillylamide, $139-43^\circ$, 75%, 3; trichloroacetovanillylamide, $76-9^\circ$, 56%, 3; bromoacetovanillylamide, $94-5^\circ$, 28%, 3; iodoacetovanillylamide, 114° , 100%, 3; nono-3,4-dihydroxybenzylamide, 78° , 68%, 25; $\Delta\omega$ -undeceno-3,4-dihydroxybenzylamide, $70-4^\circ$, 70%, 50; nono-3,4-methylenedioxybenzylamide, 92° , —, 0; nono-4-hydroxybenzylamide, 92° , 87%, 10; $\Delta\omega$ -undeceno-4-hydroxy-

benzylamide, 92°, 31%, 30; *nono-4-methoxybenzylamide*, 103°, —, —. The following intermediate products were prepd.: *vanillylamine*, m. 145–6° (N. gives 131–3°); HCl salt, m. 227° (cor.); *divanillylamine-HCl*, m. 244° (cor.); the free base, m. 92° (propyl), 104° (cor.); *piperonylamine-HCl*, m. 247° (cor.). *3,4-dihydroxybenzylamide*, brown, m. 158° (cor.). *Isopropylbutylmalonic acid*, m. 105°; distn. gives 77% of α -isopropylhexoic acid, b. 220–5°, whose chloride b. 155–8° and amide, m. 93° (cor.). γ -*Phenylpropylmalonic acid*, m. 95° (cor.), loses CO₂ at 160–70°. *O-Aceto-N-undecanovanyllamide*, m. 88° (cor.). *N-Methylol- Δ^{ω} -undecenoamide*, m. 77° (cor.). Several compds. were prepd. by both Nelson's and Einhorn's method in order to prove the constitution of the latter products.

C. J. WEST

Constituents of the kawa kawa. II. Constitution of methysticin. Y. MURAYAMA AND K. SHINOZAKI. *J. Pharm. Soc. Japan* No. 520, 526–9 (1925); cf. *C. A.* 19, 1706.—According to Winzheimer, (*C. A.* 3, 429), methysticin, C₁₅H₁₄O₆ (I), one of the crust constituents of the kawa-kawa, has the structure CH₂O₂C₆H₄CH:CHCH:CHCOCH₂CO₂Me and with alkali gives methysticic acid, C₁₄H₁₂O₆. When M and S treated I with alkali they obtained a compd. C₁₆H₁₄O₆ (II). It has one MeO, is an isomer of I and is named *isomethysticin*; it m. 186° (W's methysticic acid, m. 184°), is not acid, and does not dissolve in cold alk. carbonate or alkali solns. When heated in the latter solns., it dissolves, but on cooling, the Na salt comes down in a scaly cryst. ppt. which goes back to the original compd. when treated with an acid. When I or II is heated with a dil. mineral acid, methysticic acid (III), m. 94°, is formed as W. states. The constitutions 3,4-CH₂O₂C₆H₄CH:CHCH:CH₂COCHC(OMe)O and CH₂O₂C₆H₄CH

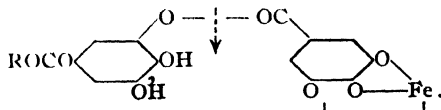

CHCH:CHCOME are suggested for I and III. The optical activity of I is better explained by M and S's formula.

S. T.

Tannins and related compounds. XXI. A rearrangement reaction of catechol KARL FREUDENBERG, GINO CARRARA AND ERNST COHN. *Ann.* 446, 87–95 (1925). 2,4,6-Trimethoxyphenyl 3',4'-dimethoxybenzyl ketone, m. 110°, in 1.2 g. yield from 1.8 g. homoveratric nitrile and 1.7 g. 1,3,5-C₆H₃(OMe)₃ with MeMgI 0.8 g. of this ketone gives 0.1 g. of α -[3,4-dimethoxyphenyl]- β -[2',4',6'-trimethoxyphenyl]- α -propylene m. 87.5–8.5°; catalytic reduction gives the propene, m. 65–6°; this is different from the methylated reduction product from tetramethylanhydrocatechol, m. 104–5°, and is, therefore, to be designated as α -[2,4,6-trimethoxyphenyl]- β -[3',4'-dimethoxyphenyl]propane. 2,3-(MeO)₂C₆H₃CH₂CHO and 1,3,5-(MeO)₂(AcO)C₆H₂CHO in Et₂O satd. with HCl, give an oxonium salt, m. 123–4°, which is catalytically reduced to 3-[3',4'-dimethoxyphenyl]-5,7-dimethoxychroman (I), m. 131°, whose Br deriv., m. 162–3°. This product is identical with the reduction product of tetramethylanhydrocatechol (II). The HCl salt of II, red-violet, m. 126–7°, on reduction gives I. *Veratryl bromide*, b. 120–5° m. 59°. Phloracetophenone di-Me ether gives a mixt. of the ether Ac(MeO)₂-C₆H₂OCH₂C₆H₃(OMe)₂, yellow, m. 148°, and the coumaranol, C₁₉H₂₂O₆, m. 118°.

C. J. WEST

Formation and aging of written characters. II. FRITZ ZETSCHE AND ALFRED LOOSLI. *Ann.* 445, 283–96 (1925); cf. *C. A.* 18, 2008.—The introduction discusses the 2nd step in the aging of ink, the formation of the sec. ink salts from iron-tannin inks. The behavior of various Fe salts of complex alcs. and phenols towards alkali is discussed from the point of view of color changes, from which it is concluded that the Fe salt splits thus:

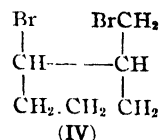

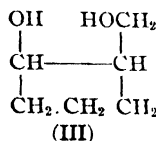

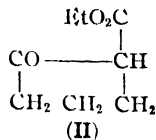

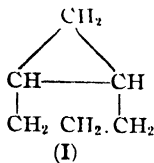

The end product of the ink salts is Fe'' oxalate, as is shown by oxidation of such salts by air. After pyrocatecholferric acid is oxidized by an air stream for 4 days, a dark olive-green compd. seps; from this HOC₆H₄CO₂H exts. about 1/3 of the Fe; this indicates that in the aging of the ink some Fe(OH)₃ is liberated and then probably bound by the decompn. products of the tannin. The following Fe salts were prepd.: *Trihydroxybenzophenone*, C₁₃H₈O₄Fe·2.5H₂O, deep black, does not melt, sol. in alkali with a red-brown color and sepn. of Fe(OH)₃; *gallacetophenone*, C₈H₆O₄Fe·1.5H₂O, olive-black powder; *maclurin*, C₁₃H₈O₆Fe·2H₂O, dark greenish black powder; *luteolin*, [(C₁₅-H₈O₆)Fe]H·3H₂O, olive-green; *quercetin*, C₁₅H₈O₇Fe·1.5H₂O, greenish black powder, does not melt, sol. in alkali with a yellow color and sepn. of Fe(OH)₃; *rhamnetin*, C₁₄H₈O₇Fe·2.5H₂O; *morin*, C₁₅H₈O₇Fe·2H₂O, olive-brown, sol. in EtOH and AcORt; *morin*,

$C_{30}H_{17}O_{14}Fe \cdot 3H_2O$; *Al gallate*, $C_7H_2O_6Al \cdot H_2O$, pure white if prepd. in atm. of CO_2 , otherwise gray to dark gray because of oxidation products; *Al maclurin compd.*, $C_{15}H_7O_6-Al \cdot 2H_2O$, yellow powder, does not melt, decompd. by alkali; *morin* gives the compd. $C_{15}H_7O_7Al \cdot 2H_2O$, light yellow powder, easily sol. in EtOH, darkens in the light. Morin and maclurin may be sepd. from fustic ext. The quantity depends upon the quality of the ext. C. J. WEST

Fungi dyestuffs. III. Atromentin. II. FRITZ KÖGL AND J. J. POSTOWSKY. *Ann.* **445**, 159-70 (1925); cf. *C. A.* **19**, 639.—The hydrocarbon, m. $205-6^\circ$, obtained by distg. atromentin (I) with Zn dust, is now shown to be terphenyl, by analysis, mol. wt. and oxidation to $PhC_6H_4CO_2H$, m. $216-7^\circ$. Detn. of the HO groups by the Grignard reagent indicates 5, as previously reported. I di-Me ether, warmed with Ac_2O and $AcONa$ and decolorized with Zn dust, gives *pentaacetylleucoatromentin di-Me ether*, m. $260-1^\circ$. Reduction of the penta-Ac deriv. of I gives the *leuco compd.*, m. $251-2^\circ$. Oxidation of 0.5 g. I with H_2O_2 in 0.1 N NaOH gives 80 mg. $p-HOC_6H_4CO_2H$; CrO_3 gives $AcOC_6H_4CO_2H$ with either the penta- or hepta-Ac deriv. Oxidation of I with dil. HNO_3 gives *m,p-O_2N(HO)C_6H_3CO_2H*, $(CO_2H)_2$, picric acid and a *dinitro deriv.*, $C_{19}H_8O_{10}N_2$, yellow, does not m. 300° , which contains 3 HO groups and yields a *tri-Ac deriv.*, yellow, m. $282-1^\circ$ (decompn.). *Leucoatromentin* is obtained from I with HI in AcOH or $NaHSO_4$, and yields the hepta-Ac deriv. The leuco compds. are not reduced by H and Pt. KOH at 100° gives the *compd.* $C_{13}H_{10}O_6$, m. 156° , crystg. with 2 H_2O , its mol. wt. in EtOH is normal. The compd. reduces $NH_4OH-AgNO_3$ in the heat, concd. H_2SO_4 gives a yellow solu., turning brown on standing. $FeCl_3$ in EtOH gives a dirty violet color, passing through green and brown to light yellow. Heated with KOH at $150-60^\circ$, there results the previously described compd., m. 183° . **IV. Xylindein, the dyestuff of "green-rotted" wood.** F. KÖGEL AND G. VON TAEUFENBACH. *Ibid.* 170-80. —Extn. of "green-rotted" beechwood with PhOH gives 0.5-0.8% of *xylindenn*, $C_{24}H_{26}O_{11}$, light yellow to deep brown rhombic leaflets, (a brief description of the crystals is given); Na salt, amorphous, sol. in H_2O with a deep bluish green color. Wool is dyed a strong bottle-green (little difference in unmordanted and Cr and Al-mordanted); cotton is scarcely colored; from a vat, both cotton and wool are dyed an emerald-green. The spectral behavior is given for $CHCl_3$, PhOH and concd. H_2SO_4 , solns. *Tetra-Ac deriv.*, yellow, mol. wt. in boiling PhBr, normal. *Di-Me ether*, blue-violet needles, contains 2 free HO groups; it is demethylated by concd. H_2SO_4 . The *diacetylxylindein di-Me ether*, yellow to yellow-green, sinters 260° , m. $291-5^\circ$; Zn dust gives the *leuco compd.*, yellow, m. $293-5^\circ$, mol. wt., 729 (av. of 17 detns.) C. J. W.

Bicyclo-(0,1,3)-hexane. N. D. ZELINSKII AND M. USHAKOV. *J. Russ.-Phys. Chem. Soc.* **56**, 67-71 (1925).—Z. and U. obtained bicyclo-(0,1,3)-hexane (I) starting from Et cyclopentanecarboxylate (II), b_{11} $101-2^\circ$. The ester was first transformed into the corresponding glycol (III), then the latter was brominated and treated with Zn. Bouveault, while reducing esters of keto acids, found that they undergo a mol. disruption resulting in the formation of primary alcs. instead of glycols, but, according to Z. and U., this observation holds true only in the case of keto esters of non cyclic structure. In the case of II the glycol is obtained under the following conditions, to 30 g. of II in 320 g. of abs. alc. in a flask under inverted condenser, 60-65 g. Na is gradually added in small pieces. The flask is heated to $120-30^\circ$ in order completely to dissolve the Na. The product is then decompd. by weak H_2SO_4 and the pptd. Na_2SO_4 filtered and washed with alc. The aq. alc. soln. is satd. with K_2CO_3 , the supernatant alc. layer dried with fused KOH, the alc. evapd. and the residue extd. with ether and fractionated. III is obtained in 45% yield in the fraction, b_{12} $136-7^\circ$. It is easily sol. in water and in alc., sol. in ether. III and 1 mol. of PBr_3 heated 12 hrs. in a sealed tube on a water bath yields a dibromide (IV). The product of reaction is washed with ice water, the IV is extd. with ether, the ether soln. is washed with water and Na_2CO_3 , dried with $CaCl_2$ and fractionated. The fraction b_{16} $109-12^\circ$ contains the dibromide (yield, 65%). It is a mixt. of the *cis*- and *trans*-forms, one of which being less stable than the other darkens, thickens and becomes opaque on keeping. IV (59 g.) dibromide, 185 g. 80% alc. and 75 g. Zn dust were refluxed 3 hrs. on a water bath, the I formed was distd. over with steam, washed and dried. It b_{746} $78-9.5^\circ$, n_{20} 1.4320; yield, 12.2 g. On being shaken with 1% $KMnO_4$ for 1.5 hrs., more than half of the substance oxidized while using up 260 cc. of the soln. The hydrocarbon which had not reacted was distd. over with steam and was found to dissolve Br vapor without reacting with it. It b_{740} $78.5-9.5^\circ$, n_{18} 1.4326, d_4^{20} 0.8178. As the phys. consts. of the substance were hardly changed, Z. and U. suppose that the $KMnO_4$ oxidized part of the hydrocarbon, or more exactly its 2 forms *cis*- and *trans*-, and not impurities. They are

at present investigating whether the above I is identical with that whose formation can be expected starting from hexahydroresorcinol.

BERNARD NELSON

Olefinic terpene ketones from the volatile oil of flowering *Tagetes glandulifera*. I. T. G. H. JONES AND F. B. SMITH. *J. Chem. Soc.* 27, 2530-9 (1925).—The volatile oil of flowering *Tagetes glandulifera* is a bright yellow, somewhat mobile liquid having the powerful cloying odor of the crushed flower; it slowly resinifies on keeping and on exposure leaves a tacky, resinous residue. The oil from the flowering plant has d_{15}^{20} 0.8638, n_D^{20} 1.4820, $[\alpha]_D$ 4°, acid value 2, Ac value 33. The oil from the flowers has d_{15}^{20} 0.8713, n_D^{20} 1.4870, $[\alpha]_D$ 2.5°. Fractional distn. of 3,800 cc. of oil gave finally 800 cc., b_{24} 72-5°, d_{15}^{20} 0.8113, n_D^{20} 1.4695, $[\alpha]_D$ 15° (consisting mainly of *d*-limonene and ocimene); 150 cc. b_{24} 85-90°, d_{15}^{20} 0.8120, n_D^{20} 1.4523, $[\alpha]_D$ 1° (I); 1,300 cc., b_{24} 55-65°, d_{15}^{20} 0.8801, n_D^{20} 1.4890 (II). I consists principally of γ,η -dimethyl- $\Delta\alpha$ -octen- ϵ -one (III), b_{10} 88-9°, b_{760} 185-6°, d_{15}^{20} 0.8351, n_D^{20} 1.4295, $[\alpha]_D$ 1.5°; it does not combine with Na_2SO_4 or NaHSO_4 , does not react with Schiff's reagent or $\text{NH}_4\text{OH}-\text{AgNO}_3$ and is unaffected by 20% H_2SO_4 after boiling several hrs. Semicarbazone, m. 92.5°; oxime, b_{760} 222°, d_{15}^{20} 0.8778, $[\alpha]_D$ 2.4°. Reduction with Na and EtOH gives γ,η -dimethyl- $\Delta\alpha$ -octen- ϵ -ol, b_{20} 92°, d_{15}^{20} 0.8305, n_D^{20} 1.440, $[\alpha]_D$ 1.75°. Catalytic reduction of the ketone gives γ,η -dimethyloctan- ϵ -one (IV), b_{760} 187-8°, d_{15}^{20} 0.8201, n_D^{20} 1.4205, $[\alpha]_D$ 4.5°; semicarbazone, m. 91.5°; oxime, b_{760} 225°, d_{15}^{20} 0.8419, n_D^{20} 1.4338. Reduction with Na and EtOH gives γ,η -dimethyloctan- ϵ -ol, b_{760} 195°, d_{15}^{20} 0.8230, n_D^{20} 1.4270. Oxidation of III with KMnO_4 in Me_2CO gave HCO_2H , AcOH , $\text{Me}_2\text{CHCH}_2\text{CO}_2\text{H}$ and β -isovaleryl α -methylpropionic acid, m. 25°, b_{25} 169-71°, $[\alpha]_D^{27}$ -2.1° (semicarbazone, m. 165°); Et ester, b_{25} 127° (semicarbazone, m. 122°). Oxidation with KMnO_4 gives AcOH and $\text{Me}_2\text{CHCH}_2\text{CO}_2\text{H}$, with a small amt. of $(\text{CO}_2\text{H})_2$; CrO_3 gives AcOH , $\text{Me}_2\text{CHCH}_2\text{CO}_2\text{H}$ and some methylsuccinic acid, m. 112°. Oxidation of IV with CrO_3 gives $\text{EtCHMeCH}_2\text{CO}_2\text{H}$, $\text{EtCHMeCO}_2\text{H}$ and AcOH ; with KMnO_4 , $\text{EtCHMeCO}_2\text{H}$, AcOH and $(\text{CO}_2\text{H})_2$. Fraction II of the oil consists of tagetone (η -methyl- γ -methylene- $\Delta\alpha$ -octen- ϵ one), pale yellow, b_{30} 102°, b_{760} ca. 205-10°, d_{15}^{20} 0.8803, n_D^{20} 1.4895, oxime, b_{25} 126°, d_{15}^{20} 0.9207, n_D^{20} 1.4820, unpleasant odor. Catalytic reduction gives IV. EtOH and Na give a compd., $\text{C}_{10}\text{H}_{18}\text{O}$, b_{760} 197°, d_{15}^{20} 0.8524, n_D^{20} 1.4190, and the pinacol, $\text{C}_{20}\text{H}_{34}\text{O}_2$ (also obtained by electrolytic reduction), b_4 183°, d_{15}^{20} 0.9258, n_D^{20} 1.4820, I no., 328. Oxidation of the ketone gave only $(\text{CO}_2\text{H})_2$ and $\text{Me}_2\text{CHCH}_2\text{CO}_2\text{H}$, with some AcOH .

C. J. WEST

Occurrence of sylvestrene. B. SANJIVA RAO AND J. L. SIMONSEN. *J. Chem. Soc.* 127, 2494-9 (1925).—A careful examn. of the oil from *Pinus sylvestris* and *P. pumilio* showed the absence of sylvestrene, although *d*- Δ^3 -carene was found. The oil from *P. sylvestris* with d_{30}^{30} 0.8661, n_D^{30} 1.4729, $[\alpha]_D^{30}$ 13.2°, acid value, 0.28, sapon. value 6.7, sapon. value after acetylation, 15, was sep'd. into 4 fractions: b_{644} 153-7°, d_{30}^{30} 0.8553, n_D^{30} 1.4637, $[\alpha]_D^{30}$ 20.0° (17.4% of original oil), nearly pure α -pinene; 157-61°, 0.8553, 1.4656, 16.7° (18.7%), mixt. of α -pinene, β -pinene and *d*-carene; 161-7°, 0.8556, 1.4676, 11.7° (30%), practically *d*- Δ^3 -carene; 167-76°, 0.8573, 1.4711, 8° (8.1%), nearly pure carene. The oil from *P. pumilio* with d_{30}^{30} 0.9221, n_D^{30} 1.4831, $[\alpha]_D^{30}$ -9.3°, acid value 7.5, sapon. value, 31.5 (after acetylation, 89.6) was similarly fractionated, the 4 fractions showing the same qual. compn.

The chemistry of pinene. I. L. KONDAKOV. *Caoutchouc & gutta-percha* 21, 12489-92 (1924); 22, 12837-8, 12870-3 (1925); cf. *C. A.* 18, 2337.—A critical discussion of past researches on the prepn., constitution and properties of pinene and its derivs., with analyses of essential oils contg. such compds.

C. C. DAVID

Camphor series. X. Synthesis of camphor. I. Catalytic action of reduced copper on borneols. B. MASUMOTO. *Mem. Coll. Sci. Kyoto Imp. Univ.* 9A, 219

-21(1925). (In English).—M. finds that oxidation of borneols to camphor by the catalytic action of reduced Cu is more effective in yield and simpler in manipulation than oxidation by chemicals. By this method *d*-borneol and *l*-isoborneol are equally oxidized to camphor without any side-reaction. Under similar conditions menthol yields menthone and a small amt. of menthene. The menthone formed in this way from *d*-menthol suffers racemization while camphor resulting from borneols by the same treatment suffers no racemization. CuO prepd. from $\text{Cu}(\text{NO}_3)_2$ and NaOH soln., reduced with H at 200° and heated at 200–220° forms a suitable catalyst for oxidizing borneols to camphor. Camphor when passed over reduced Cu or reduced Ni with pure H gives no borneol.

REYNOLD C. FUSON

***l*-Camphor-10-sulfonic acid from synthetic camphor.** HENRY BURGESS AND C. S. GIBSON. *J. Soc. Chem. Ind.* **44**, 496–8T(1925).—The following solubilities in 100 g. H_2O at 8.5° are reported: brucine *d*-camphor-10-sulfonate, 1.783 g; *l*-deriv., 5.094 g. (m. 251–3°, $[\alpha]_{\text{D}}^{25}$ 35.0° (c 1.767)); strychnine *d*-deriv., 3.205 g. (m. 275–8°, $[\alpha]_{\text{D}}^{25}$ –13.7° (c 1.212)), *l*-deriv., 3.053 g. ($[\alpha]_{\text{D}}^{25}$ –37.9° (c 2.070)). The synthetic camphor was transformed into the 10- SO_3H acid by Reychler's method. When the inactive acid was neutralized with 0.5 an equiv. of brucine and 0.5 an equiv. of NH_4OH , the brucine *d*-salt sepd. to the extent of 87% of the theoretical quantity and was optically pure after 2 crystns from H_2O . The acid obtained from the mother liquor was then treated with sufficient strychnine to neutralize the calcd. amt. of *l*-acid present and NH_4OH to neutralize the *d*-acid. The product which sepd. consisted of mixed crystals of the *d*- and *l*-acids. If the acid from the mother liquor is crystd. from AcOEt 5 times it is practically pure *l*-acid. Details of typical expts. are given. C. J. WEST

Reaction of acetyl derivatives of organic acids with benzene and aluminium chloride. J. CRYER. *Trans. Roy. Soc. Can. Sec. III* [3], **19**, 29(1925).—The oily residue obtained when a mixt. of Bz_2O and Ac_2O reacted with C_6H_6 and AlCl_3 gave almost quant. Ph_3CO and very little PhCOMe . Aspirin, AcOPh and AcOEt react vigorously with C_6H_6 and AlCl_3 , giving PhCOMe . Aspirin gave a 70% yield and the other esters a smaller yield. J. W. SHIPLEY

Occurrence of free radicals in chemical reactions. III. HEINRICH WIELAND, HUGO VON HOFE AND KARL BÖRNER. *Ann.* **446**, 31–48(1925); cf. C. A. **17**, 95.—*Benzoylhydrazotriphenylmethane*, m. 118°, in 70% yield from Ph_3CCl and BzNHNH_2 ; oxidation with $\text{K}_2\text{Fe}(\text{CN})_6$ gives 50–80% of the *azo compd.*, S-yellow, decomp. 80–1° (vigorous evolution of N); it is unstable even in cold solns. Warmed in $\text{C}_6\text{H}_5\text{Me}_2$ or very pure petroleum ether in a N atm. to 30–40°, N is vigorously evolved, the soln. becomes deep red, then gradually turns to yellow, the residue gave 60–70% β -benzopinacolin, m. 179°. In the presence of O, there results about 50% β -benzopinacolin and 10% $(\text{Ph}_3\text{C})_2\text{O}$; a small amt. of BzOH is also formed. In CCl_4 there results some BzCl ; this is not formed when the decompn. occurs in CHCl_3 . *p*-Bromobenzoylhydrazotriphenylmethane, m. 177°; the *azo compd.* light yellow, decomp. 67–8°; in soln. this gives an intense carmine-red color and *p*-bromobenzopinacolin, m. 181°; in CCl_4 , there results some *p*- $\text{BrC}_6\text{H}_4\text{COCl}$. *p*-Toluylylhydrazotriphenylmethane, m. 136–9°; the *azo compd.*, m. 60° (decompn.), in soln. gives a deep red color. *p*-Dimethylaminobenzoylhydrazotriphenylmethane, m. 192–5° (60% yield); *azo compd.*, yellow, m. 77° (decompn.) (60–70% yield); decompn. in C_6H_6 , $\text{C}_6\text{H}_5\text{Me}_2$, etc., gives a deep carmine-red color and 25% of dimethylaminobenzopinacolin, m. 224–6°; in an atm. of O_2 , there results from 1.28 g. 0.1 g. of $(\text{Ph}_3\text{C})_2\text{O}$ and small amts. of the pinacolin. *Benzoylhydrazotritolylmethane*, m. 206–8° (decompn.); the *azo compd.*, m. 70–2° (decompn.); decompn. in a CO_2 or N atm. gives 40% of the pinacolin, m. 148–9°; in an atm. of O, there also results the pinacolin besides some $(\text{MeC}_6\text{H}_4)_2\text{C}_2\text{O}$; 1.6 g. *azo compd.* gives 0.064 g. BzOH and 0.010 g. CO_2 . *p*-Tolylhydrazo-*p*-tritolylylmethane, m. 176–8°; the *azo compd.*, yellow, decomp. 60–5°; in a CO_2 atm. there results 40% of tetra-*p*-methylbenzopinacolin, m. 145–6°. *p*-Dimethylaminobenzoylhydrazotritolylmethane, m. 180°; the *azo compd.* yellow, m. 69–70°. *Et triphenylmethylhydrazocarboxylate*, m. 145° (90% yield); the *azo compd.*, light yellow, m. 98° (decompn.). Decompn. begins about 80°, giving a light red soln.; in an O atm. there is formed some $(\text{Ph}_3\text{C})_2\text{O}$ but the principal product is $\text{Ph}_3\text{CCO}_2\text{Et}$, m. 118°. *Et p*-tritolylylhydrazocarboxylate, m. 134–5°; the *azo compd.*, pale yellow, m. 96° (decompn.). Decompn. of 0.9 g. of the *azo compd.* gives 0.0164 g. *di*-*Et peroxidedicarboxylate* (also prepd. from ClCO_2Et and Na_2O_2), a very unstable and explosive compd. Azodibenzoyl is stable at 80–110°; in boiling $\text{C}_6\text{H}_5\text{Me}_2$ about 25–30% of the total N is split off. IV. The reaction of silver salts of carboxylic acids with iodine. H. WIELAND AND F. GOTTFALD FISCHER. *Ibid* 49–76.— AcOAg at room temp. takes up 1 equiv. I without liberating CO_2 ; addn. of H_2O gives AcOH , AgI and AgIO_3 , the latter in the ratio of 5:1. Ag capronate likewise takes up 1 equiv. I, giving

a light yellow product, sol. in hot petroleum ether (80–110°); heated with quartz powder, it splits off 42% CO₂, giving 71% of Am capronate and a small amt. of free acid. Cl₃C-CO₂H splits off AgCl at 80°; at room temp. it absorbs 1 equiv. I; with H₂O it yields free acid. AgI and AgIO₃; heated at 110°, it gives AgCl, thus indicating a complex decompn. *Ag Et succinate*, long needles; soly. at 25°, 2.18%; absorbs 1 equiv. of I, the product being somewhat sol in Et₂O. Heated at 150° for 2 hrs., the product gives 29% CO₂ (of 2 mols.); the acid portion of the residue contains some succinic acid but principally the ester acid; there is also formed some maleic ester acid; the neutral part contains Et succinate, and *Et β-carbomethoxyethyl succinate*, b₁₂ 166–71°, mol. wt., 265, 261 (in camphor). PhCH₂CO₂Ag absorbs 1 equiv. of I; in the decompn. of the product there is a temporary carmine-red color and liberation of a trace of I. Heated to 80°, there is split off 44% CO₂ and the resulting product contains 10% PhCH₂CO₂H and 68% benzyl phenylacetate, b₁₂ 175–6°, b. 318–20°. The compd. with Ph₃CCO₂Ag splits off 48% of CO₂ at 80°; from 3.95 g. Ag salt there results 0.09 g. Ph₃CCO₂H and 2.2 g. Ph₃C triphenylacetate, m. 183–4°; the characteristic Ph₃C color was not observed during the reaction; heating the product in an O atm. gave no trace of (Ph₃C)₂O; this indicates that the radical Ph₃C is not formed in the reaction. The products from cholic and cholanolic acids do not split off CO₂ when heated. Crotonic acid likewise gives no CO₂ when the Ag salt and I are heated, but strongly unsatd. acids are formed. PhCH-CHCO₂Ag and I, at 105–10°, split off 26% CO₂, giving 36% of the acid and a neutral, unsatd. resin, which begins to decomp. at 180° at 0.3 mm. PhC-CO₂H gives a Ag salt only in cold solns., since at about 40° it splits off CO₂, giving PhC-CAG; the Ag salt does not react with I in the cold; in boiling C₆H₆ 2.14 equivs. I are taken up, giving tri-iodostyrene and phenyliodoacetylene. BzOAg decomps. at 150–60°; in Et₂O or C₆H₆ suspension, it absorbs 1 equiv. I at room temp.; decompn. with H₂O gives BzOH, AgI and AgIO₃ (similar to AcOH). Heated with quartz sand at 160–80°, 34% of 2 mols. CO₂ are split off, giving 30% BzOH, about 10% PhI, a little BzOPH and BzOC₆H₄I. Glycolic acid as the Ag salt and I in C₆H₆ split off 35% CO₂, giving some HCHO; lactic acid splits off 46% CO₂, giving AcH; mandelic acid splits off 47% CO₂, giving 60% BzH; benzoic acid splits off 42% CO₂, giving Ph₂CO (CO₂Ag)₂, I and quartz at 40–5°, split off 98.4% CO₂. CH₂(CO₂Ag)₂ gave 62% CO₂. The thermal decompn. of the intermediate product from (CH₂CO₂Ag)₂ and I gives 29% CO₂ and maleic acid. Ag tartrate splits off CO₂ slowly at 165–70°; the org. substances were partly carbonized and the mass contained no AgIO₃. Ag adipate and I, 2 hrs. at 90° and 1 hr. at 150°, give 34% CO₂; the residue contained δ-valerolactone. Ag phthalate and I under boiling C₆H₆ form a complex without liberation of CO₂; addn. of H₂O gives the acid and AgIO₃; heating at 130° gives only the anhydride and AgIO₃. Ag terephthalate and I at 200° give only traces of CO₂. The Ag salt of *trans*-hexahydrophthalic acid and I at 70–5° split off CO₂; at 130° after 1 hr., 31% of CO₂ was split off. The *cis*-acid reacts with I at 120–5°; after 2 hrs., heating 21% CO₂ was split off. Ag maleate reacts with I at 50–5°; an intermediate product could not be found; from 33 g. Ag salt and 25.4 g. I (25% CO₂ split off), there was isolated 0.2 g. fumaric acid and 1.65 g. maleic anhydride. Ag fumarate (8.25 g.) and 6.5 g. I (26% CO₂ split off) at 125° gave 1.5 g. pure fumaric acid. Bz₂O₂ (4.5 g.), 5 g. I and quartz, heated at 100° for 4 hrs., gave 0.68 g. BzOH, 1.16 g. PhI and 0.21 g. Ph₂. The mechanism of these various reactions is discussed.

Colored salts of the di- and triphenylmethane series. W. MADELUNG. *J. prakt. Chem.* **111**, 100–46 (1925).—An extensive theoretical discussion of the constitution of the salts of the di- and triphenylmethane series.

C. J. WEST

Action of organomagnesium compounds upon cyanohydrins. II. Y. ASAHINA AND M. ISHIDATE. *J. Pharm. Soc. Japan* No. **521**, 624–8 (1925).—Using the same method as given in paper I (C. A. **17**, 3028), A and I obtained a ketimine-HCl (I) from *p*-MeOC₆H₄MgBr and 6,2-Me(HO)C₆H₃CH(OH)CN. An attempt to produce a benzoil deriv. by hydrolysis of I, resulted in failure. When I is oxidized with Fehling soln., a substance m. 96° was obtained (yield 10%), which is a benzil deriv. (II). When II is heated with alc. KOH, a cryst. compd. (III), m. 172–3°, is formed which is a benzilic acid. An attempt to demethylate III by boiling with AcOH-HBr, resulted in the formation of a resinous amorphous substance. With AcOH and HI, however, A and I obtained needles, m. 143°, which dissolve in Na₂CO₃ and give no color with FeCl₃ nor with coned. H₂SO₄ and do not correspond to phylloulcin. I, II and III have the structures 2,6 - Me(MeO)C₆H₃CH(OH)C(NH HCl)C₆H₄OMe (p), Me(MeO)C₆H₃-COCOC₆H₄OMe and Me(MeO)C₆H₃C(OH)(CO₂H)C₆H₄OMe, resp.

S. T.

Synthesis of phenolphthalein. E. SHPITALSKII AND B. LUKASHEVICH. *J. Chem. Ind. (Russia)* **1**, 2628 (May–June, 1925).—Conforming to Bayer's method of prepn.

gives 65.2% of pure phenolphthalein (I). This method was modified by S. and L. thus: The melt resulting from heating under good stirring $C_6H_4(CO)_2O$, PhOH and $SnCl_2$ 5 hrs. is poured into boiling water, the PhOH is steamed off, the I is washed with water, treated with steam again to remove the last traces of PhOH and finally dried. The temp. of condensation has a paramount influence on the purity of the crude I obtained. If it is raised above 120° even for a short time, the product is very impure. The most favorable temp. is $111-6^\circ$. The yield of the crude I freed from inorg. impurities is about 85% and that of pure I about 79%. The synthesis of I has also been effected by using $C_6H_4(CO_2H)_2$ instead of $C_6H_4(CO)_2O$. With 16.8 parts acid, 20 parts PhOH, 25 parts $SnCl_2$, heated 5 hrs., then by varying the temp. of reaction the following results are obtained:

Temp.	Yield of crude I	M. p. of the product	Quantity of org. impurities insol in alkali
$115-120^\circ$	75	215-249	0.4
$114-116^\circ$	74.3	250-252	0.2
$107-111.5^\circ$	65.4	250-253	0.2

(The figures representing crude I do not include inorganic admixtures.) If the amt of $SnCl_2$ is increased to 39.7 parts, the yield in crude I of the same degree of purity can be raised to 85%. By effecting the condensation at $109-113^\circ$ during 10 hrs. with the increased quantity of $SnCl_2$, the yield can be increased by about 2%. To purify crude I, S. and L. recommend washing it with a small quantity of cold MeOH, crystg. from MeOH and washing.

BERNARD NELSON

Conversion of *dl*-phenyl- α -naphthylglycolic acid into ketones. ALEX. MCKENZIE AND H. J. TATTERSALL. *J. Chem. Soc.* **127**, 2522-30 (1925). — *Phenyl- α -naphthylchloroacetyl chloride* (I), m. $155-6^\circ$. I (5 g.) and excess $PhMgBr$ give 1.1 g. α -naphthyl-deoxybenzoin, m. $109-10^\circ$, which reacts with $MeMgI$ to give α,β -diphenyl- α -[α -naphthyl]propan- β -ol, m. $124-5^\circ$. *Phenyl- α -naphthylacetyl chloride* (II), m. $74.5-5.5^\circ$ (16 g. from 19 g. of acid). C_6H_6 and $AlCl_3$ with II give a compd., $C_{18}H_{15}O$, m. $115.5-6.5^\circ$, gives a deep yellow color with cold concd. H_2SO_4 and a compd. m. $240-1^\circ$, giving a brown color with H_2SO_4 changing to olive green. II and $MeMgI$ give *phenyl- α -naphthylacetone*, m. $84.5-5^\circ$, gives a crimson color with cold concd. H_2SO_4 ; alc. KOH gives $C_{18}H_{17}CH_3Ph$ and $AcOH$. *Phenyl- α -naphthylacetone*, m. $125-6^\circ$, gives an orange-yellow color with cold concd. H_2SO_4 . *Phenyl- α -naphthylmethyl *p*-tolyl ketone*, m. $141-2^\circ$, gives a yellow color with cold concd. H_2SO_4 . C. J. WEST

Addition of azodicarboxylic esters to aromatic hydrocarbons. R. STOLÉ AND G. ADAM. *J. prakt. Chem.* **111**, 167-75 (1925); cf. *C. A.* **18**, 3177. — *Di-Me naphthylene-1,4-dihydrazinotetracarboxylate*, m. 250° (decompn.), reduces hot $NH_4OH-AgNO_3$ contg. NaOH, results in 4 g. yield from 2.6 g. $C_{10}H_8$ and 5.8 g. $(HNCOMe)_2$; the *di Et ester*, m. 234° (decompn.). Heating with HI and $AcOH$ gives 1,4- $C_{10}H_6(NH_2)_2$, whose *di-Bz deriv.* m. 276° (decompn.). *p*-Bis[dicarboxymethylhydrazino]diphenyl, m. 246° (decompn.); the *Et ester*, m. 195° (decompn.). Decompn. gives $(H_2NC_6H_4)_2$. Bis[dicarboxymethylhydrazino]-2,7-fluorene, m. 200° ; *Et ester*, m. 152° ; decompn. gives dibenzoyldiamino-2,7-fluorene, m. 324° ; the dibenzylidene deriv., ochre-yellow, m. 248° (decompn.). Dicarboxymethylhydrazino-1-anthracene, m. 265° (decompn.); the $AcOH$ soln. has a deep violet fluorescence; *Et ester*, pale green, m. 241° (decompn.). Dicarboxymethylhydrazino-9-phenanthrene, m. 214° ; the *Et ester*, m. 158° . The solns. have a deep violet fluorescence; an aq. suspension reduces $NH_4OH-AgNO_3$ after addn. of NaOH. C. J. WEST

Acenaphthene series. III. ω -Aminoacenaphthene and further observations on *m*-aminoacenaphthene. G. T. MORGAN AND H. M. STANLEY. *J. Soc. Chem. Ind.* **44**, 493-6T (1925); cf. *C. A.* **19**, 3268. — Four NH_2 derivs. of acenaphthene are theoretically possible and M. and S. have completed the series by prep. ω - or 1-aminoacenaphthene. A new scheme for designating positions in the acenaphthene group has been proposed wherein one of the side-chain carbons is designated 1 and the numbering continued clockwise; thus H-bearing carbons of the fused nuclei are numbered from 2 to 7, with 8 reserved for the other side-chain carbon. This scheme closely relates acenaphthene to $C_{10}H_8$ and is particularly advantageous in working with di-derivs. Acenaphthene quinone with PCl_5 gave 83% of dichloroacenaphthenequinone, which with Zn and HOAc gave 45% of acenaphthenone, yielding with NH_2OH acenaphthenone oxime, m. $183-4^\circ$. Reduction with Al-Hg in moist ether, Zn and NH_4Cl in 50% alc., $TiCl_3$ and $Na_2S_2O_4$ did not give satisfactory results. Zn and HOAc gave a mixt. of acenaphthene and the desired base, isolated as the HCl salt (35% yield), decompg. 270° . Picrate, yellow, blackening 240° , m. 260° (decompn.). The free base sublimes easily, m. 135° , is strongly

alk. and absorbs CO_2 . An attempt to synthesize acenaphthenone from C_{10}H_8 and $\text{Cl-CH}_2\text{COCl}$ by AlCl_3 led to 69% of β -naphthyl chloromethyl ketone, b_{10} 185–7°, m. 30°. The vapor irritated the mucous membranes. Picrate, yellow, m. 89°. By alk. KMnO_4 the ketone yielded β - $\text{C}_{10}\text{H}_7\text{CO}_2\text{H}$, m. 181° and an oil presumably β - $\text{C}_{10}\text{H}_7\text{COCO}_2\text{H}$. *m*-Aminoacenaphthene-HCl with NaNO_2 gave yellow acenaphthene-3-diazonium chloride, which decompd. slowly with loss of N at room temp., decompd. 150–60°. Heated to 120° it lost H_2O of crystn., then N. With CuCl the diazonium salt gave an oil, 3-chloroacenaphthene, blackening 250°, but not boiling below 290°. A picrate orange, m. 79–80°, was formed. Coupled with diazotized p - $\text{C}_6\text{H}_4(\text{NH}_2)\text{NO}_2$ the 3- NH_2 compd. gave 88% bronze-red 1'-nitrobenzeneazo-3 aminoacenaphthene, m. 200°. Concd. H_2SO_4 developed a deep blue color; there was no change with alc. soda.

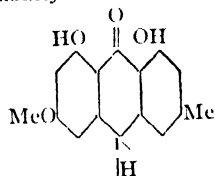

G. ALBERT HILL

Acenaphthene series. IV. Aminoacenaphthenesulfonic acids. G. T. MORGAN AND V. E. YARLEY. *J. Soc. Chem. Ind.* **44**, 513–5T (1925); cf. preceding abstr. *Na* 4-aminoacenaphthene-5-sulfonate (I), in 68% yield by nitration of the sulfonate at *no* over 25°. Reduction with $\text{Na}_2\text{S}_2\text{O}_4$ gives *Na* 4-aminoacenaphthene-3,5-disulfonate, which, diazotized at 5°, gives a light green diazo compd.; on boiling with dil. H_2SO_4 this yields a sulfone, $\text{C}_{10}\text{H}_7\text{O}_2\text{S}_2\text{Na}$. Reduction of I with Fe and H_2O gives the light brown *Na* 1-aminoacenaphthene-5-sulfonate, which gives, with acenaphthene-4-diazonium chloride, a reddish brown azo dye, coloring wool and silk brown shades. 4-Aminoacenaphthene and 80% H_2SO_4 on the H_2O bath for 3 hrs. give the light gray 2-sulfonic acid deriv. (II), whose diazo compd. is olive green; boiling this with H_2SO_4 does not give a sulfone but a 4 HO deriv. 4-Benzamidoacenaphthene-2-sulfonic acid, light brown. II and p - $\text{O}_2\text{NC}_6\text{H}_4\text{N}_2\text{Cl}$ give a deep red azo compd., $\text{C}_{18}\text{H}_{11}\text{O}_4\text{N}_4\text{SNa}$; 4-diazoniumacenaphthene gives a reddish brown compd., $\text{C}_{24}\text{H}_{15}\text{O}_4\text{N}_5\text{SNa}$, dyeing wool and silk reddish brown, β - $\text{C}_{10}\text{H}_7\text{N}_2\text{Cl}$ gives a dark red azo deriv. with the diazo deriv. of II, while 4-aminoacenaphthene HCl in AcONa soln. gives a deep bluish red aminoazo deriv., $\text{C}_{23}\text{H}_{18}\text{O}_4\text{N}_3\text{SNa}$, H_2SO_4 gives a bluish green color; wool and silk are dyed brownish shades of red. Reduction of 4-nitroacenaphthene by $\text{Na}_2\text{S}_2\text{O}_4$ gives principally the 4- SO_3H acid deriv. but about 6% of the 3-deriv. The latter is only slightly sol. in H_2O , does not couple with diazo compds. and is diazotized with difficulty at low temps. C. J. WEST

Reduction products of the hydroxyanthraquinones. VII. WM. B. MILLER AND A. G. PERKIN. *J. Chem. Soc.* **127**, 2684–91 (1925); cf. *C. A.* **19**, 3269. — In the reduction of alizarin 2-Me ether by SnCl_4 and 33% HCl there results a small amt. of 4-hydroxy-3-methoxyanthrone (I), pale yellow, m. 202° (*Ac* deriv., lemon-yellow, m. 185–6°), oxidized by CrO_3 to acetylalizarin 2-Me ether and a much larger amt. of 1-hydroxy-2-methoxyanthrone (II), orange red, m. 135–7° (*di-Ac* deriv., yellow, m. 202°). I, H_2SO_4 and $\text{C}_2\text{H}_5\text{OH}$ give benzalazarin Me ether, orange, m. 247–9°, sol. in H_2SO_4 with a violet red color (isolated as the *Ac* deriv., pale yellow, m. 205–7°); this ether was also obtained by the partial methylation of benzalazarin. II, treated as above, gives isobenzalazarin, (III), orange, m. 260–2° (*Ac* deriv., bright orange-yellow, m. 243–5°; *di-Ac* deriv., yellow, m. 214°), H_2SO_4 gives a green, fluorescent, orange-red liquid and with boiling alkalis, orange yellow solns. which with Ba(OH)_2 yield orange-red ppts. The *Ac* deriv. in boiling EtOH-AcOK gives an orange K salt. The Me ether, deep yellow, m. 196–8° (*Ac* deriv., yellow, m. 178–80°). III dyes mordanted wool shades which are very distinct from those given by benzalazarin. Anthrapurpurin di-Me ether, orange-red, m. 234–5° (*Ac* deriv., yellow, m. 204–5°), from triacetylaurthrapurpurin and Me_2SO . Reduction with SnCl_4 and HCl gives anthrapurpurinanthranol di-Me ether, isolated as the *di-Ac* deriv., m. 178°. C. J. WEST

Chrysarobin. R. EDER AND F. HAUSER. *Arch. Pharm.* **263**, 436–51 (1925); cf. *C. A.* **19**, 2202. — In a continued examl. study of the non-antioxidizable dimol reduction products of hydroxymethylanthraquinones, *viz.*, dehydroanthranol mono Me ether and ararobinol, it is shown with considerable probability that the former is a deriv. of

dihydrodianthrone (dianthrone), of the type

, while the

yellow substance known as ararobinol is like the former a binuclear quinone and stands in similar relationship to chrysophanic acid anthrone as the dehydro compd. to emodin monomethyl ether anthrone.

W. O. E.

Composition of rubicene, $C_{26}H_{14}$ (reply to K. Dziewonski and J. Suszko). RUDOLF PUMMERER AND H. M. ULRICH. *Ber.* 58B, 1806-8(1925).—Rubicene has been prepd. by D. and S.'s pyrogenic method (*Bull. acad. sci. Cracovie* 1921, 53, 2173; cf. C. A. 17, 1459) but the residue from the $CHCl_3$ ext. of the crude product was sublimed under 2 mm., the sublimate extd. with $CHCl_3$ and the residue from the ext. fractionated from alc., ligroin, C_6H_6 , xylene, $PhNO_2$ and xylene again. There was finally obtained a pure product, m. 306° . Eight microanalyses by 4 different men on products prepd. both by D. and S.'s and by P. and U.'s method establish the compn. $C_{26}H_{14}$. C. A. R.

Univalent oxygen. IV. STEFAN GOLDSCHMIDT, ADOLF VOGT AND MAX ALBERT BREDIG. *Ann.* 445, 123-41(1925); cf. C. A. 18, 3375.—The halogen of chlorophenanthrol, even under very energetic conditions, is very difficultly and only partially removed. The Cl in dichlorophenanthrone (I) is more reactive and while the desired reaction was not obtained with $EtONa$, $PhONa$ gives 25-30% of 9-diphenoxy-10-*keto*-9,10-phenanthrene dihydride, m. $136-7^\circ$ (decompn.), decomps. in the sunlight in moist air, especially at summer temp., in a few days, splitting off $PhOH$. Mol. wt. in C_6H_6 normal. Reduction with Zn dust in $AcOH$ gives a nearly quant. yield of phenanthrenehydroquinol mono-*Ph* ether, m. $140-1^\circ$; it is pptd. unchanged from alk. solns. by acids. Oxidation in 3% $NaOH$ with $K_3Fe(CN)_6$ gives 9,9'-diphenoxy-10,10'-phenanthryl peroxide, m. $166-7^\circ$ (decompn.); in the cold its solns. are colorless but in boiling $CHCl_3$ or C_6H_6N a pale rose color develops, indicating dissociation; the mol. wt. in boiling $PhNO_2$ is normal. Reduction with Zn in $AcOH$ gives the *Ph* ether; warming with HNO_3 gives phenanthrenequinone (II); Br in $CHCl_3$ gives the same compd. $PhOH$ and I at 50° give 9-*bis*-*p*-hydroxyphenyl-10-phenanthrone, m. 248° ; *o*- MeC_6H_4OH gives the corresponding *o*-hydroxyacetyl deriv., m. $291-2^\circ$ (decompn.) II and $N_2H_4 \cdot H_2O$ in dil. $EtOH$ give phenanthrazine, m. about 450° ; the concd. H_2SO_4 soln. is deep blue. II or the mono-Cl deriv. is reduced by $SnCl_2$ in $AcOH$ satd. with HCl to 9-phenanthrol, m. $150-1^\circ$ (yield, 50-60%); oxidation with $K_3Fe(CN)_6$ gives an amorphous red-brown compd., probably not the simple phenanthroxyl, since reduction with $(PhNH)_2$ does not give the original 9-phenanthrol. Br gives 9-bromo-10-phenanthrol, m. 127° ; in $CHCl_3$ PhO_2 gives the peroxide, m. about 109° (decompn.); the solns. are decompd. by sunlight at 0° in 10-15 min., while at 0° in the dark after 24 hrs. solns. show the deep red color of the free radical. Titration with $(PhNH)_2$ indicates that equil. between the peroxide and the free radical is reached in about 1 hr., with 30% radical. Beer's law does not hold for solns. of the free radical. The dissociation const. in $CHCl_3$ contg. 0.5% C_6H_5N at 0° is $k = 2.9 \times 10^{-4}$, at 15° , 7×10^{-4} ; the corresponding values for the Cl deriv. are 5.6 and 5 (at 20°)

C. J. WEST

Hydrogenation of furan derivatives. T. KARIYONE. *J. Pharm. Soc. Japan*, No. 515, 1-22(1925).—Four methods of catalytic hydrogenation were used, viz., Pt black, colloidal Pt soln., $Pd-BaSO_4$ and colloidal Pd soln. The furan derivs. used were: (1) Those contg. $-CH_2-$ or $-CH=$ at the α -position of the furan nucleus (furfurethylene, furylacrylic acid, furfuralacetone, furylphenylmethane, and furyl alc. (2) Those having $-CO-$ group at the α -position (furyl Me ketone, furyl Ph ketone, furoin, furil and furyl-ethyl ether). (3) Furfural and its derivs. (furfural, furfural di-Et acetal and furfurylidene diacetate. (4) Furan carboxylic acid and its derivs. (pyromucic acid, Et pyromucate, pyromucic amide, furfuronitril, β -(?)-nitropyromucic acid, dehydromucic acid, di-Me dehydromucate and α -methylfuran- β -carboxylic acid. The results of hydrogenation of these substances are given in detail, including the kind of catalyzer and the solvent used, no. of mols. H taken up and the hydrogenated products and other phys. properties such as m. p. and b. p. In general, the conclusions may be summarized as follows. The members of group (1) are the most easily hydrogenated, next (2) and α - CO_2H acid derivs. are rather difficult to be reduced. The dehydromucic acid can be easily reduced by Na-Hg, but difficultly by catalytic hydrogenation. In (3), the di-Et ester is the easiest to be reduced, furfural being the most difficult. When 1 mol. H was added to those having a side chain with a double bond, K. found that furfurethylene gave a large amt. of the original substance and a trace of the 6-hydro deriv., while furylacrylic acid gave quant. furylpropionic acid. Certain interesting comparisons between the speeds of the H absorption by Ph and furan derivs. are illustrated in 5 curves. The following 7 derivs. of furan could not be hydrogenated by Pt black or Pd catalyzers:—1,4,2- $Me_2(HO_2C)$, 1,3,2- $Me_2(HO_2C)$, 1,3,4,2- $Me_3(HO_2C)$, 1,4,2,3- $Me_2(HO_2C)_2$, 4,3,1- $Me(HO_2C)(HO_2CCH_2)$, 1,4,2- $Ph_2(HO_2C)$, 1,4,2,3- $Ph_2(HO_2C)_2$. S. T.

Some furan derivatives. A FUJITA. *J. Pharm. Soc. Japan* No. 519, 456-71 (1925).—The chem. behavior of derivs. of furfuralacetone (I) is reported. I was prepd. according to Claisen and Ponder's method (*Ann.* 223, 144), and reduced by Na-Hg in $MeOH$ contg. $AcOH$. Two products are formed; (a) furfurylaceton, d_4^{20} 1.0308, n_D^{26}

1.47446, mol. refraction 37.66, and (b) the portion b_{12} 93–5°, which probably has the structure, $\text{O} \cdot \text{CH} \cdot \text{CH} \cdot \text{CH} \cdot \text{CCHCH}_2\text{COMe}$

instead, not only the double bond in the side chain becomes satd., but the furan nucleus itself becomes hydrogenated. Next furfurylacetone is converted to an oxime, d_4^{20} 1.0907, n_D^{18} 1.51266, mol. refraction 42.08, which on reduction with Na-Hg in AcOH-MeOH, gave δ -furylbutan- β -amine; the interesting pharmacol property of this compd will be reported by Kubota. When difurfuralacetone was reduced similarly by Na-Hg, F. obtained 2 derivs.: (a) difurylacetone, and (b), a compd. $\text{C}_{13}\text{H}_{12}\text{O}_3$, m. 188°, which is probably 3,4-difurylpentanone. Supplementary data on mol. refraction are given for some furan derivs. S T

Production of cyclotelluripentanedione dichlorides. G. T. MORGAN, F. J. CORBY, O. C. ELVINS, EVELINE JONES, R. E. KELLETT AND C. J. A. TAYLOR. *J. Chem. Soc.* 127, 2611–25 (1925).—In the reaction of TeCl_4 with β -diketones, certain constitutional features must be present in order that the ketone may react in the desired sense; these conditions are discussed and are illustrated in the following preps. *n*-Propylpropionylacetone, b_{750} 210°, gives an intense bluish purple color with FeCl_3 , has a pleasant terpenoid odor and yields a greenish gray Cu salt, m. 178° (decompn.). With TeCl_4 in CHCl_3 it gives 62% of 2-methyl-4-propylcyclotelluripentane-3,5-dione 1,1-dichloride, darkens 145°, blackens 150°; $\text{K}_2\text{S}_2\text{O}_8$ in ice-cold H_2O readily reduces it to the free ketone, Au-yellow, m. 102° (slight decompn.). 3-Isopropylpropionylacetone, b_{750} 195°, does not give a color with FeCl_3 and does not yield a Cu salt; TeCl_4 gives the corresponding 4-isopropyl dichloride, darkens 168°, blackens 173°; the free ketone is light yellow, m. 127°. 3-Methyl-3-ethylpropionylacetone, b_{10} 118° (25% yield), fragrant odor, does not give a color with FeCl_3 , a Cu salt nor could a Te salt be isolated, though it may have been present in the tar which is formed. 3-Benzylpropionylacetone, b_{20} 185°, fragrant odor, gives an intense reddish violet color with FeCl_3 , and a pale gray, silvery Cu salt m. 182°. TeCl_4 gives the 4-benzyl dichloride, m. 168°; the free ketone, yellow, m. 121° (decompn.); it does not sublime in vacuo. 3-Isobutylacetylacetone, b_{10} 93 1°, gives a bluish purple color with FeCl_3 and a steel-gray Cu salt, m. 158°. TeCl_4 gives 4-iso-butylcyclotelluripentane-3,5-dione 1,1-dichloride, m. 142°; the free ketone, yellow, m. 150°. β -Phenylpropionylacetone yields a Cu salt, grayish blue, m. 158°. TeCl_4 gives a non-cryst. dichloride, from which $\text{K}_2\text{S}_2\text{O}_8$ liberates 2-benzylcyclotelluripentane-3,5-dione, yellow, decompn., 159°. 2-Decylcyclotelluripentane-3,5-dione 1,1-dichloride, m. 89° (21% yield); the free ketone, pale yellow, m. 98–9° (decompn.). $\text{PhCH}_2\text{COCH}_2\text{COEt}$ and TeCl_4 give a product m. 64–8°, which gives the enolic reaction with FeCl_3 and is very sensitive to H_2O ; it is not a member of the series under consideration. 2-Methylcyclotelluripentane-3,5-dione dioxime, grayish yellow, darkens 153°, m. 161.5°; a small amt. of a sol. product (in boiling C_6H_6), m. 135–50°, was probably impure dioxime. 2-Methyl-4-ethylcyclotelluripentane-3,5-dione yields a monoxime, bright yellow, m. 157°, and a dioxime, grayish yellow, blackens 170°, decompn. 182°. 3-sec-Butylacetylacetone, b_{13} 109–11° (9% yield); it yields no Cu deriv. but with TeCl_4 gives 37% of 3-sec-butylcyclotelluripentane-3,5-dione 1,1-dichloride, darkens 162°, m. 168–9°; the free ketone, primrose-yellow, m. 145°. The corresponding sec-butyl dichloride, darkens 136°, m. 162°, results in 35% yield from *dl*-sec-amylacetylacetone, b_{16} 116° (gives a purple color with FeCl_3 and a greenish gray Cu salt, m. 120°); the free ketone, pale yellow, m. 138–9°. 3-sec-Amyldipropionylmethane, b_{18} 137°, gives a purple color with FeCl_3 and a greenish gray Cu salt, m. 105°; the condensation with TeCl_4 gave only oily products. *Te* acetylmethylcyclohexanone, m. 159–60°, $[\alpha]_{589}^{17}$ 106.4° (0.5 g. in 10 cc C_6H_6).

C. J. WEST

Interaction of tellurium tetrachloride and monoketones. G. T. MORGAN AND O. C. ELVINS. *J. Chem. Soc.* 127, 2625–32 (1925).—*Te* bisacetone dichloride, m. 126–8°, in 17% yield from Me_2CO , TeCl_4 and CHCl_3 ; reduction causes decompn. with liberation of *Te*. *Te* methyl ethyl ketone trichloride, m. 101–1.5° (75% yield). *Te* bismethylpropyl ketone dichloride, m. 92–3°, decompn. in contact with mother liquor. *Te* bismethylisopropyl ketone dichloride softens 85°, m. 90° (52% yield). *Te* bismethylbutyl ketone dichloride, m. 62° (1.1 g. from 3 g. ketone). *Te* bismethylisobutyl ketone dichloride, m. 95° (45% yield). *Te* diethyl ketone trichloride, m. 77–8° (84.6% yield). *Te* dipropyl ketone trichloride, m. 70° (77% yield); hydrolyzed in moist air. *Te* pinacolin trichloride, softens 110°, m. 114–5° (21% yield); the mother liquor deposited *Te* bispinacolin dichloride, m. 191–2° (26% yield); while this is much more permanent in the air than

the trichloride, all attempts to remove the Cl were unsuccessful. EtCOCHMe_2 and TeCl_4 gave only a brown sirup, but $(\text{iso-Pr})_2\text{CO}$ did not react with TeCl_4 . *Te phenyl-ethyl ketone trichloride*, m. $114-5^\circ$ (61% yield). *Te phenyl propyl ketone trichloride*, m. $128-9^\circ$ (71% yield). *Te phenylbenzyl ketone trichloride*, m. $142-3^\circ$ (60% yield); this is reduced by aq. $\text{K}_2\text{S}_2\text{O}_8$ to a yellow solid, which is very unstable and decomps. on exposure or in CHCl_3 soln.

C. J. WEST

Complex metal compounds of indigo blue. III. K. KUNZ AND W. STÜHLINGER. *Ber. 58B*, 1860-8(1925); cf. C. A. 18, 686. --This work was carried out to obtain further data on the valence relationships in the complex and addn compds of indigo (I) with metals, NaOH, alcoholates, SnCl_4 , Grignard reagents, etc., the guiding principle being to find a parallelism between I and chlorophyll. Like the latter, so also I under suitable conditions reacts with Cu or Zn acetate, forming compds identical with those previously obtained with the metals; almost the calcd. amt. of AcOH is split off at the same time. Only the acetates of the heavy metals react in this way; $\text{Mg}(\text{OAc})_2$, e. g., forms no Mg compd. The mechanism of the reaction has not yet been established experimentally. *N,N'*-Diphenylindigo (II) also reacts with $\text{Cu}(\text{OAc})_2$ with formation of a new type of complex contg. Cu with an abnormally high coordination no. With FeCl_3 the indigoid dyes form addn. products contg. 1 mol. salt to 1 or 2 mols. dye; MeCN is the best solvent, the least trace of $\text{C}_6\text{H}_5\text{N}$ leading to a regeneration of the components; $\text{Fe}(\text{OAc})_3$ and enol Fe salts do not react. To exclude the possibility that it is the two C.O. groups in I and its derivs which are responsible for the formation of these addn compds [2-methylindyl] [2'-methylindolydene]-methane (III) was studied and found to react like I with heavy metal acetates and FeCl_3 . Na-K in xylene at 140° seems to form true substitution products, with evolution of the calcd. amt. of H and only a barely perceptible change in color. II-Cu compd., III.Cu , from II shaken with $\text{Cu}(\text{OAc})_2$ in dry $\text{C}_6\text{H}_5\text{N}$ until the blue color of the soln. changes to a pure green is extremely sensitive in soln. to moisture, AcOH , etc.; attempts to det. the amt. of AcOH split off in its formation gave positive but, owing to the great sensitiveness of the dye towards the oxidizing action of the $\text{Cu}(\text{OAc})_2$, not conclusive results. 7,7'-Dimethylindigo (V) (0.5 g.) with dry FeCl_3 in MeCN at 30° gives 0.2 g. of a compd. 2IV.FeCl_3 , almost black crystals forming in MeCN or CHCl_3 green solns. which rapidly deposit IV on addn. of a drop of H_2O , while in PhMe at $70-80^\circ$ is obtained a compd. IV.FeCl_3 , dark green powder slightly decompd. even by washing with dry PhMe, instantly regenerates IV with traces of moisture, acids, even abs. alc. With Zn and Cu acetates in $\text{C}_6\text{H}_5\text{N}$, SnCl_4 in C_6H_6 , IV reacts like I while thioindigo does not react even with SnCl_4 . The compd. II.FeCl_3 (0.4 g. from 0.5 g. II and FeCl_3 in MeCN at 30°), blue-black crystals, strongly dichroitic by transmitted light under the microscope, immediately decompd. by H_2O or alc.; on shaking in Et_2O suspension with concd. NaOH or $\text{C}_6\text{H}_5\text{N}$ it decompd. through an exceedingly unstable red intermediate product. The 7,7'-Me₂ deriv. of II with K yields a very unstable red compd. $(\text{C}_{30}\text{H}_{22}\text{O}_2\text{N}_2)\text{K}$. Compds of III: III.Cu , crystals with greenish metallic luster, from III in $\text{C}_6\text{H}_5\text{N}$ treated below 85° dropwise with $\text{Cu}(\text{OAc})_2$, regenerates III with acids. III.Ag , red. III.FeCl_3 , from the components in MeCN, green, more stable towards H_2O than the I analog.

Complex metal compounds of chlorophyll. I. K. KUNZ AND K. SEHRBUNDT. *Ber. 58B*, 1868-76(1925).--The striking similarity of the chlorophyllins to the metal compds. of indigoid derivs described in the preceding abstr. led to a renewed study of chlorophyll (I); the first results of this study are reported in the present paper. Dried powd. nettle leaves were extd. with Me_2CO according to Willstätter, the I was saponified with KOH in MeOH, the K chlorophyllin (II) subjected to alk. degradation in autoclaves and the di- CO_2H acid rhodophyllin (III) or the mono- CO_2H acid pyropheophyllin (IV), depending on the conditions, was isolated in cryst. form. At first the Mg-contg. phyllins were isolated according to W. and the porphyrins were then prepd. from them but in the later work no attempt was made to isolate the very sensitive phyllins and the metal-free compds. were prepd. directly by a simplified process. The series of isomeric CO_2H acids, starting from pheophytin (V), was also studied and a shortened process for obtaining directly the metal-free compds. erythroporphyrin (VI) and phylloporphyrin (VI), without isolating the phyllins, was worked out. Removal of the last CO_2H group from the end products of both series by heating with very small amts. of soda-lime (40-50 mg.) gave in very poor yield ethiophyllin (VII) and ethioporphyrin (VIII); the amt. of crystd. VIII available was about 120 mg. Comparison of I with indigo shows that both have a pronounced ability to form complexes with metals and mol. compds., the reaction being accompanied by a deepening in color. The resulting compds. generally contain 1 atom of metal or 1 mol. of salt to every 4 pyrrole nuclei. Their reactivity towards chem. agents varies widely; while very sensitive towards acids,

they are quite stable towards alkalis; in both the indigo and the I derivs., the firmness of the union increases from the very labile alkali compds. to the extraordinarily inert Cu (indigo) or Mg (I) compds. Attempts to eliminate any possible disturbing influence of CO_2H groups in the prepn. of heavy metal compds. of I derivs. by using mostly porphyrin esters led to the formation of a no. of complex Cu and Zn compds. with 1 atom metal to 4 pyrrole nuclei; rhodoporphyrin (IX) with cold $\text{Cu}(\text{OAc})_2$ gave a compd. with 8 pyrrole nuclei per atom of Cu. As in the case of indigo, so the porphyrin esters smoothly react in xylene with Cu, without evolution of H_2 , yielding the same compds. as with $\text{Cu}(\text{OAc})_2$. Similar (qual.) results are obtained with Zn- or Mg Al. ZnCO_3 on shaking in cold C_6H_6 with porphyrin esters forms with surprising ease complex compds. with 1 atom Zn per mol. of ester. Repetition of Willstätter's work on the prepn. of a cryst. Fe compd. of IX gave only unchanged IX contaminated with Fe salts but FeCl_3 in MeCN gives a compd. entirely analogous to that obtained from indigo. Finally, with K in anhyd. solvents porphyrin esters, like indigo, react very slowly or not at all, no evolution of H_2 can be observed. *Me pyrroporphyrin (X) compds.*: *X.Cu*, from X and $\text{Cu}(\text{OAc})_2$ in MeCN at $60-70^\circ$, red needles, does not decomp. in hot AcOH-HCl , also obtained from X and Cu powder in C_6H_6 at $100-20^\circ$. *X.Zn*, easily decompd. by HCl . $\text{C}_{33}\text{H}_{34}\text{O}_2\text{N}_4\text{K}$, from X and K in C_6H_6 -ligrou in ice, obtained as a red-violet soln. instantly changed to the original brown-red by H_2O , alc. or acids. *Cu and Zn compds. of Me rhodoporphyrin; FeCl}_3* compd., $(\text{C}_{33}\text{H}_{34}\text{O}_4\text{N}_4) \cdot \text{FeCl}_3$, brown red, decompd. by acids, H_2O and $\text{C}_3\text{H}_5\text{N}$. C. A. R.

Crystallographic data for some organic compounds. GILBERT GREENWOOD *Mineralog. Mag.* 20, 393-405(1925).—*Menthyl bromomethylcyclophenylhydrazonocarboxylate*, m. p. $133-4^\circ$, is orthorhombic-hemihedral with $a:b:c = 0.923:1.064:1$. *Menthyl bromomethylcyclo-p-tolylhydrazonocarboxylate*, m. p. $155-6^\circ$, is also orthorhombic hemihedral with $a:b:c = 0.927:1.064:1$. *4,5-Dibromo-1-methylglyoxaline-HCl*, m. p. 179° , and d. = 2.082 is monoclinic-holohehdral with $a:b:c = 0.897:1.065:1$, $\beta = 82.12^\circ$. *Glyoxaline-4(5)-sulfonic acid*, m. p. 307° and d. = 1.838 is tetragonal with $c = 0.839$, $\epsilon = 1.625$, $\omega = 1.551$. *2-Methylglyoxaline-4(5)-sulfonic acid*, m. p. 279° and d. = 1.686, is monoclinic-holohehdral with $a:b:c = 0.529:1.0408$; $\beta = 60.38^\circ$. *4(5)-Bromoglyoxaline-5(4)-sulfonic acid*, m. p. 280° and d. = 2.085, is also monoclinic-holohehdral with $a:b:c = 0.851:1.0492$; $\beta = 61.15^\circ$. *2-Methyl-4(5)-bromoglyoxaline-5(4)-sulfonic acid*, m. p. 266° and d. = 1.968, is orthorhombic-holohehdral with $a:b:c = 0.594:1.0432$. *1-Methyl-5-bromoglyoxaline-4-sulfonic acid*, m. p. 284° and d. = 2.186, is monoclinic-holohehdral with $a:b:c = 0.945:1.0512$; $\beta = 85.24^\circ$. *Triphenylphosphine oxide*, m. p. 153° and d. = 1.206 is orthorhombic holohehdral with $a:b:c = 0.630:1.0390$. *p-Tolylazobenzylformaldoxime* with d. = 1.234 is monoclinic-holohehdral with $a:b:c = 1.352:1.1216$; $\beta = 83.17^\circ$. A fission product of lupulone, $\text{C}_{38}\text{H}_{46}\text{O}_4$, m. p. 91° and d. = 1.150 is orthorhombic-holohehdral with $a:b:c = 0.610:1.0701$. *5-Carbolime*, m. p. 225° and d. = 1.352, is monoclinic-holohehdral with $a:b:c = 0.8013:1.04285$, $\beta = 68.46^\circ$. W. F. HUNT

Dissociation constants of imidazole-4,5-dicarboxylic acid. H. PAULY. *Ber.* 58B, 1791-2(1925) — Reply to Lehmstedt (*C. A.* 19, 2825). P. and Ludwig used the Bredig method (*Z. physik. Chem.* 13, 288(1894)) to det. the 2nd dissociation const. of the acid. C. A. R.

2-m-Xylidino-5-ethoxy-4,5-dihydrothiazole. V. K. NIMKAR AND F. L. PYMAN. *J. Chem. Soc.* 127, 2746(1925); cf. Burtles, Pyman and Roylance, *C. A.* 19, 1709 — The action of concd. H_2SO_4 on acetalyl-m-xylalylthiocarbamide gives 2-m-xylidino-5-ethoxy-4,5-dihydrothiazole (?), m. $102-3^\circ$ (cor.), whose picrate, m. 152.4° (cor.) (previously reported $142-3^\circ$). C. J. WEST

Thiodiazines. II. Condensation of ω -bromoacetophenone with 4-substituted thiosemicarbazides. PRAFULLA KUMAR ROSE. *Quart. J. Ind. Chem. Sec.* 2, 95-114(1925). — Whereas the condensation of thiosemicarbazides with PhCOCH_2Br (I) to form thiazole derivs. has been found to depend upon the basic character of the 2 extreme NH_2 groups, (cf. *C. A.* 19, 831; 7, 1478) it is now seen that the basic character of the 4-N atom partaking in ring formation cannot be regarded as the sole factor in detg. the relative yields of thiazole derivs. Although no independent method for measuring the mobility of the H atom is available, it would seem that the relative proportions of thiodiazine and thiodiazole formed in the different cases depends upon this relative mobility. The results obtained indicate that the formula for a substituted thiosemicarbazide is $\text{RNHC(SH)}: \text{NNHR}'$ rather than $\text{RN:C(SH)NHNHR}'$. The methylation product of 2-amino-5-phenyl-1,3,4-thiodiazine previously regarded as 2-methylamino-5-phenyl-1,3,4-thiodiazine (cf. *C. A.* 19, 831) is now regarded as 2-imino-3-methyl-5-phenyl-2,3-dihydro-1,3,4-thiodiazine (cf. *C. A.* 17, 1640; 18, 677). The thiodiazines are stable compds. forming salts

with acids; the alkylamino derivs. are less stable than the arylamino derivs.; boiling with H_2O or aq. alkali causes decompn.; the isomeric thiazole hydrazones are more basic and susceptible to oxidation. Phenyl-, *o*- and *p*-tolylthiazoles give a ppt. with HNO_3 , a property absent with the α -naphthylthiazole and the thiazines. Six g. of **I** and 5 g. $PhNHCSNHNH_2$ (**II**) gave 6.5 g. of 2-phenylamino-5-phenyl-1,3,4-thiodiazine-*HBr* (**III**), m. 191° , and 13% of 2-keto-3,4-diphenyl-2,3-dihydro-1,3-thiazole hydrazone-*HBr* (**IV**) which softens at 206° and m. $224-6^\circ$ (decompn.); the free bases obtained by treatment of the *HBr* salts with NH_4OH and recrystn. from $C_6H_6N + H_2O$ are colorless and m. 198° and 175° (decompn.), resp.; the *Ac* deriv. of **III** is amorphous and m. 110° . **Ac_2O** and **II** form 1-acetyl-4-phenylthiosemicarbazide (**V**), m. 173° . Equimol. amts. of **I** and **V** gave 2-keto-3,4-diphenyl-2,3-dihydro-1,3-thiazole acetylhydrazone-*HBr*, m. 224° , on treatment with NH_4OH yields the amorphous free base (**VI**); on boiling with dil. HCl it yields **IV**. Acetone 4-phenylthiosemicarbazone, from Me_2CO and **II**, m. 128° and when treated with 1 mol. **I** gave 2-keto-3,4-diphenyl-2,3-dihydro-1,3-thiazole isopropylidenhydrazone-*HBr*; NH_4OH converts this to the free base, yellow, m. 165° . Anisaldehyde (**XII**) and **II** form anisylidene 4-phenylthiosemicarbazone, m. $180-1^\circ$ and when treated with **I** gives 2-keto-3,4-diphenyl-2,3-dihydro-1,3-thiazole anisylidenhydrazone, m. 161° ; it is also obtained from **XII** and **VI**. Benzylidene-4-phenylthiosemicarbazide and **I** form 2-keto-3,4-diphenyl-2,3-dihydro-1,3-thiazole benzylidenhydrazone, yellow, m. 191° . 4-*p*-Tolylamino-5-phenyl-1,3,4-thiodiazine-*HBr* from **I** and *p*- $MeC_6H_4NHCSNHNH_2$ in abs. alc. was recrystd. from alc. and m. 195° ; free base, m. 179° ; *Ac* deriv., m. 115° . The *HBr* salts of 2-*o*-tolylamino-5-phenyl-1,3,4-thiodiazine (**VIII**) and 2-keto-3-*o*-tolyl-4-phenyl-2,3-dihydro-1,3-thiazole hydrazone are both obtained by interaction of *o*- $MeC_6H_4NHCSNHNH_2$ and **I**; the former m. 185° and the latter m. $206-8^\circ$ (decompn.); the pale yellow free bases, m. 148° and 136° , resp. When **VIII** is treated with 1 mol. **Br** in $AcOH$, a mono-*Br* deriv., $C_{10}H_9N_3SBr$, m. $155-6^\circ$ is obtained. 2-Allylamino-5-phenyl-1,3,4-thiodiazine-*HBr* from **I** and $CH_2=CHCH_2NHCSNHNH_2$, obtained in 90% yield, m. 165° , the free base, greenish yellow, m. 99° . α - $C_{10}H_7NHCSNHNH_2$ and **I** yield the *HBr* salts of 2- α -naphthylamino-5-phenyl-1,3,4-thiodiazine (**IX**) and 2-keto-3- α -naphthyl-4-phenyl-2,3-dihydro-1,3-thiazole hydrazone, m. 220° (decompn.) and 208° (decompn.), resp.; the free bases, m. $166-7^\circ$ and 179° , resp., the former being yellow and the latter pale greenish yellow; the *Ac* deriv. of **IX** is a white amorphous powder. β - $C_{10}H_7NHCSNHNH_2$ and **I** gave 76% of 2- β -naphthylamino-5-phenyl-1,3,4-thiodiazine-*HBr*; a soln. in C_6H_6N on adding H_2O yields the yellow free base, m. 153° . **I** and $MeNHCSNHNH_2$ (**X**) react to form the yellow 2-methylamino-5-phenyl-1,2,4-thiodiazine, m. $144-5^\circ$ and the yellow 2-keto-3-methyl-4-phenyl-2,3-dihydro-1,3-thiazole isopropylidenhydrazone, m. $92-3^\circ$, also obtained from acetone 4-methylthiosemicarbazone (from **X** and Me_2CO , m. 118°) and **I**. Anisylidene-4-methylthiosemicarbazone (**XI**) (from **XII** and **X**, m. 207°) and **I** yield the *HBr* salt of 2-keto-3-methyl-4-phenyl-2,3-dihydro-1,3-thiazole anisylidenhydrazone (**XI**), m. $235-6^\circ$ (decompn.); the free base, m. 128° ; **XI** is also obtained from **XII**, **X** and **I**. A yield of 2.7 g. of 2-ethylamino-5-phenyl-1,3,4-thiodiazine, m. 158° , was obtained from 2.38 g. $EtNHCSNHNH_2$ and **I**; from the mother liquors a very small amt. of material was obtained which is probably 2-keto-3-ethyl-4-phenyl-2,3-dihydro-1,3-thiazole isopropylidenhydrazone. On boiling **III** with concd. HCl **IV** is obtained; the *p*- and *o*-tolylthiazine derivs. similarly yield the corresponding *p*- and *o*-tolylthiazole derivs. N. A. LANGE

Preparation of heterocyclic aldehydes. III. Triazolaldehydes. C. A. ROJAHN AND HANS TRIELOFF. *Ann.* **445**, 296-306 (1925); cf. *C. A.* **18**, 2339. 1-Phenyl-5-methyl-1,2,3-triazole-4-carboxyl chloride, b_p 105° (slight decompn.), m. 133° ; amide, m. $217-8^\circ$; anilide, m. $149-50^\circ$. Catalytic reduction of the chloride gives 1-phenyl-5-methyl-1,2,3-triazol-4-aldehyde (**I**), m. 52° ; semicarbazone, m. $226-7^\circ$; aminoguanidone nitrate, m. 224° ; anil, m. 256° ; syn-oxime, m. 162° ; attempts to acetylate the oxime gave the nitrile of 1-phenyl-5-methyl-1,2,3-triazole-4-carboxylic acid, m. $63-4^\circ$. The condensation product of **I** and $NCCH_2CO_2Et$, $C_{15}H_{14}O_2N$, m. $126-7^\circ$. The oxime, reduced with $Na-Hg$ in $EtOH-AcOH$, gave 1-phenyl-4-aminomethyl-5-methyl-1,2,3-triazole-*HCl*, m. $182-4^\circ$, whose picrate, yellow, m. 328° . **I** and Na in $AcOEt$ yield 1-phenyl-5-methyl-1,2,3-triazol-4-acrylic acid, m. 189° . The mother liquor from **I** contains 1-phenyl-5-methyl-1,2,3-triazole, m. 64° , and 1-phenyl-4,5-dimethyl-1,2,3-triazole, m. 98° , whose picrate, m. 131° . In 1 reduction expt. there resulted the acid anhydride, m. 189° . 1,5-Diphenyl-1,2,3-triazole-4-carboxyl chloride, yellowish, m. 101° ; amide, m. 174° ; anilide, m. $147-8^\circ$. 1,5-Diphenyl-1,2,3-triazol-4-aldehyde, m. $104-5^\circ$ (70% yield); oxime, m. 176° ; semicarbazone, m. 224° ; aminoguanidone nitrate, m. 205° ; anil, m. $136-7^\circ$; $CNCH_2CO_2Et$ condensation product, m. $165-6^\circ$. 1-Phenyl-5-chloro-1,2,3-triazole-4-carboxylic acid, m. $189-90^\circ$; *Et* ester, m. 78° ; chloride, m. $125-6^\circ$; amide, m. $182-3^\circ$; anilide, m.

146°. Attempts to prep. the chloride of 1-phenyl-1,2,3-triazole-4,5-dicarboxylic acid gave a resinous mass, but the CHCl_3 soln. with NH_3 gave the *diamide*, m. 228°. 2-Chloro-5-methyl-1,3,4-triazole and ClCO_2Et gave 2-chloro-3(or 4)-*N*-carbethoxy-5-methyl-1,3,4-triazole, m. 58–9°.

C. J. WEST

Pyrylium compounds. XV. Arylated pyridines. 7. *m*-Substituted triphenylpyrylium compounds. W. DILTNEY AND W. RADMACHER. *J. prakt. Chem.* **111**, 153–66 (1925); cf. *C. A.* **19**, 519.—2-[*m*-Nitrophenyl]-4,6-diphenylpyrylium chloride-ferric chloride (I), greenish yellow, m. 218°, in 2.6 g. yield from 2- $\text{O}_2\text{NC}_6\text{H}_4\text{Ac}$ and 2.5 g. PhCOCH:CHPh in AcOH and FeCl_3 ; the pseudo base (2-[*m*-nitrophenyl]-4,6-diphenylpyranol) is amorphous and very unstable and was analyzed as the *picrate*, orange-red, m. 251° and the *perchlorate*, Au-yellow, m. 276–7°. I in EtOH suspension, treated with NH_3 , gives 2-[*m*-nitrophenyl]-4,6-diphenylpyridine, m. 141–2° (*purate*, yellow, m. 184°; *perchlorate*, pale yellow, m. 176°). SnCl_2 in HCl gives the *m*-amino deriv., m. 151°; *Bz deriv.*, m. 224–5°; *dipicrate*, yellow, m. 207°; *monoperchlorate*, yellow, m. 235°, *diperchlorate*, m. 170–1°. 4-[*m*-Nitrophenyl]-2,6-diphenylpyrylium chloride-ferric chloride, yellow, m. 237–8° (35% yield); the pseudo base, yellow, m. 135°; in 1.1 H_2SO_4 it shows a green fluorescence; *purate*, reddish yellow, m. 248°, *perchlorate*, dark yellow, m. 268°. 4-[*m*-Nitrophenyl]-2,6-diphenylpyridine, m. 150–1°; *picrate*, yellow, m. 188°; *perchlorate*, m. 271–2°. The *m*-amino deriv., m. 168–9° and gives a violet fluorescence in concd. H_2SO_4 ; *dipicrate*, m. 209°. 4-[*m*-Aminophenyl]-2,6-diphenylpyrylium *diperchlorate*, m. 281–2° (yield, 15%); the pseudo base, m. 132–3°, shows a greenish blue fluorescence in concd. H_2SO_4 and is not very stable in the air; *hydrobromide*, decomps. above 290°; *dipicrate*, brown needles, m. 232–3°; in C_6H_6 there results a yellow *monopicrate*, m. 230–1°; in AcOH , a red *monopicrate*, m. 236–7°. 2-[*m*-Methoxyphenyl]-4,6-diphenylpyrylium *perchlorate*, yellow, m. 194°; the *m*-HO deriv., yellow, m. 193–4°, in concd. H_2SO_4 it shows a pale bluish green fluorescence. 2-[*p*-Methoxyphenyl]-4,6-diphenylpyrylium *perchlorate*, yellowish red, m. 235–6°; the *p*-HO compd., Au-yellow, m. 278–80°. The relative value for the basicity of the perchlorates of these compds., assuming the basicity of triphenylpyrylium perchlorate to be 1, is, m-NO_2 , 0.8; m-MeO , 2.4; p-MeO , 2.49; m-HO , 2.6; the *p*-HO deriv. showed no turbidity after adding 180 cc. H_2O to 1 g. of the substance, and crystd. unchanged from the soln. Even after adding 40 l. water there was no change.

Methylation of tyrosine. EMIL ABDERHALDEN AND ERNST SCHWAB. *Z. physiol. Chem.* **148**, 17–22 (1925).—By treating a suspension of *dl*-tyrosine in $\text{Et}_2\text{O-EtOH}$ with CH_3N_2 and evapg. the solvent, a strongly basic oil was obtained, from which the *O*-*Me* ether of tyrosine *Me ester*, b_{12} 158°, was isolated by extrn. with Et_2O . *HCl salt*, m. below 100°. The residue consisted of *dimethyltyrosine Me ester*, and from this the corresponding *anhydride* was obtained by sublimation. In the presence of a small amt. of H_2O the methylation of tyrosine proceeds still further with formation of tyrosine betaine, m. 222° (decompu.). *HCl salt*, m. 107°; *chloroplatinate*, m. 232° (decompu.).

A. W. DOX

Action of ammonia upon bisimmonium bromides. JULIUS V. BRAUN AND FRIEDRICH ZOBEL. *Ann.* **445**, 247–66 (1925); cf. Schlotz, *Ber.* **31**, 1700 (1898).—S. reported that the action of NH_3 on $\text{C}_6\text{H}_4(\text{CH}_2)_2\text{NBr}(\text{CH}_2)_2\text{C}_6\text{H}_5$ gave a bisxylylenimine; this view seemed to be supported by its thermal decompu. into dihydroisindole and piperidine (*C. A.* **17**, 390). Doubt was thrown on this interpretation by the action of NH_3 upon the bromide from piperazine and 1,5- $\text{C}_6\text{H}_{10}\text{Br}_2$, which gave rise to $\text{H}_2\text{N}(\text{CH}_2)_4\text{N:C}_6\text{H}_{10}$; this raised the question as to whether all the so-called bisimines were not really primary tertiary bases. Synthesis of such compds. proved this assumption. Piperidine and $\text{Cl}(\text{CH}_2)_4\text{NHBz}$ give the *Bz deriv.*, b_{12} 240°, m. 57–8°, of δ -aminobutylpiperidine, b_{12} 102–5°, d_4^{25} 0.9075, identical with the previously described tetramethylenepentamethylenebisimine; di- PhSO_2 deriv., needles. $\text{PhO}(\text{CH}_2)_6\text{NH}_2$ and $\text{Cl}(\text{CH}_2)_4\text{NHBz}$ give 70% of *phenoxyamylbenzoyltetramethylenediamine*, whose *HCl salt* m. 171–3°; 10 hrs. heating with concd. HCl at 120° gives ϵ -chloroamyltetramethylenediamine-di-*HCl*, m. 246–8°, the free base from which b_{12} 103–5° and is identical with the above. The compd. previously described as bispyrrolidine is more likely δ -aminobutylpyrrolidine, whose *dibenzenesulfonyl deriv.*, m. 146°. $\text{PhO}(\text{CH}_2)_6\text{NH}_2$ and $\text{Cl}(\text{CH}_2)_6\text{NHBz}$ give *phenoxybutylbenzoylpentamethylenediamine-HCl*, m. 160–2°; concd. HCl gives δ -chlorobutylpentamethylenediamine-di-*HCl*, m. 215–7°; *chloroplatinate*, m. 215–6°. ϵ -Aminoamylpyrrolidine, b_{10} 112–4°, d_4^{20} 0.920; *HCl salt*, m. 150–2°; *chloroplatinate*, m. 212°, crystals, with 1 H_2O ; *tetra-Me deriv.*, m. 290°. Benzoylaminopiperidine, b_{10} 255°, m. 74°; ϵ -aminoamylpiperidine, b_{13} 115° (previously termed bispiperidine, *Ber.* **38**, 176 (1905)). ϵ -Aminoamylconiine, b_{10} 145°, d_4^{19} 0.898; this is identical with the compd. obtained from

NH₂ and piperidine-coniinium bromide. The "bisxylylenimine" of S. is really *o*-amino-methylbenzylidihydroisoindole (I), b₁₂ 220–5°, m. 72° and synthesized from dihydroisoindole and ClCH₂C₆H₄CH₂NHIBz; the previously described *p*-O₂NC₆H₄CO deriv. is the *mono*- not the di-. *Salicylidene deriv.*, m. 113°. *Monobenzenesulfonyl compd.*, m. 151°. NaNO₂ in AcOH gives the *o*-HO deriv., m. 114°. I yields a *picrolonate*, m. 230°. I also results by heating ClCH₂C₆H₄CH₂NH₂ alone or in alk. soln., the yield of dihydroisoindole being only about 20%. With ClCH₂C₆H₄CH₂CH₂NH₂, the yield of tetrahydroisoquinoline is about 50%, the remainder being *o*-aminoethylbenzyltetrahydroisoquinoline, oil, b₁₂ 240–3°, mol. wt (camphor) 250; *picrolonate*, m. 230°; phenylsulfonate, m. 162°; *salicylidene deriv.*, yellow, m. 67°; *p*-nitrobenzoate, m. 109°. *o*-Amino-methylbenzylpiperidine, b₁₁ 158–60°; *picrate*, m. 192°; *benzenesulfonyl compd.*, m. 94°; *Bz deriv.*, m. 111°. *ε*-Aminoamylidihydroisoindole, b₁₁ 180°; *Bz deriv.*, m. 99°; *picrate*, m. 140°; *benzenesulfonyl compd.*, m. 123°. C. J. WEST

Absorption spectra and lactam-lactim tautomerism. R. A. MORTON AND EDWARD ROGERS. *J. Chem. Soc.* 127, 2698–700(1925).—Absorption spectra are shown for carbostyryl and its *N*- and *O*-ether and for *o*-hydroxycarbanil and its *N*- and *O*-ethers. The work of Hartley and Dobbie (*J. Chem. Soc.* 75, 640(1899)) on isatin and *o* hydroxycarbanil is unsatisfactory and the revision shows that absorption spectra do not provide any very obvious means of deciding the structure. With 1,3,5-C₆H₃(OH)₃ and carbostyryl, repetition of the work does not controvert the conclusions of H. and D. In general, conclusions based on the shape of absorption curves need careful examn. before reliance can be placed on them. Absorption spectra measurements should be interpreted by quant. considerations concerning frequencies of max. absorption.

Quinoline derivatives. I. Synthesis of substituted 2-phenyl-4-methyl-quinolines.

HANNS JOHN AND FR. NOZICKKA. *J. prakt. Chem.* 111, 65–82(1925).—PhNH₂ (9.3 g.), 43.8 g. PhCH:CHAc (I) and 6 g. PhNO₂, warmed with 25 g. concd. H₂SO₄ in 10.8 g. H₂O 6 hrs., give 1.5 g. of the picrate of 2-phenyl-4-methylquinoline (II); 28 g. PhNH₂, 36 g. H₂O and 2.7 g. PhNO₂, mixed with 35.4 g. concd. H₂SO₄ with strong cooling and then with 10.9 g. I and heated 5 hrs. at 135–40°, give 4% II; from 15.3 g. PhNH₂, 11.6 g. H₂O, 2.6 g. PhNO₂, 41 g. concd. H₂SO₄ and 12.2 g. I, there results 0.2% II; other variations of the ratio of H₂O and H₂SO₄ gave a max. of 9.5% of II; 4.4 g. PhNH₂ HCl, 5 g. I, 17 drops H₂O and 3 drops concd. HCl give 12.8% II. *p*-MeOC₆H₄NH₂ HCl (5.4 g.), 5 g. I, 3 drops HCl and 17 drops H₂O, heated 6 hrs. in a sealed tube at 135°, give 8.8% of 2-phenyl-4-methyl-6-methoxyquinoline, m. 129°; very dil. solns. in org. solvents show a blue fluorescence; *HCl salt*, needles; *HgCl₂ salt*, needles, nearly insol. in boiling H₂O; *ferrocyanide*, needles; *picrate*, yellow needles. The corresponding *ε*-HO deriv., m. 153°, is formed in 5.3% yield from *p*-EtOC₆H₄NH₂ HCl, I and HCl by heating 20 hrs. at 110°; *HCl salt*, long needles, *HgCl₂ salt*, needles; *ferrocyanide*, needles; *chromate*, yellow needles; *picrate*, needles. The 6-HO deriv., m. 211–2°, results in 7.7% yield from *p*-HOC₆H₄NH₂, I and HCl in a tube at 110° for 40 hrs.; *HCl salt*, H₂SO₄ salt, *K salt*, *Na salt*, *HgCl₂ salt*, *ferrocyanide*, *chromate* and *picrate*. *Ethers*: *Pr*, m. 110°; *iso-Bu*, m. 101°; *iso-Am*, m. 117°; *allyl*, m. 96.5°; *phenacyl*, m. 143°. *p*-MeC₆H₄NH₂ and I with H₂SO₄ give 8.2%, with HCl, 14.2%, of 2-phenyl-4,6-dimethylquinoline, m. 93–3.3°; *HCl*, H₂SO₄ and *HgCl₂ salts*, *ferrocyanide*, *chromate* and *picrate* 2-Phenyl-4-methyl-5(or 7)-methoxyquinoline, m. 99.5°, in 14.8% yields; same salts as above. The corresponding 5(or 7)-EtO deriv., m. 105.5°, also results in 14.8% yields; same salts as above. The 5(or 7)-hydroxy deriv., m. 228°, results in 12.1% yields; same salts as above. 2-Phenyl-4,5(or 4,7)-dimethylquinoline, oil (16.3% yield); same salts as above. 2(or 3)-Phenyl-4(or 1)-methylnaphthoquinoline, m. 152° (24.6% yields); same salts as above. II. H. JOHN AND G. WÄBER. *Ibid* 83–99.—2-Phenyl-4,8-dimethylquinoline, m. 91.5°, (14.3% yield); *HCl*, H₂SO₄ and *HgCl₂ salts*; *ferrocyanide*, *chromate*, *hydropiodide* and *picrate*. 2-Phenyl-4-methyl-8-chloroquinoline, m. 79–80° (1.5% yield); various salts. The 8-HO deriv., m. 58°, results in 10.6% yields from 7.25 g. *o*-HOC₆H₄NH₂, 7.5 g. I, 7 drops concd. HCl and 3.6 cc. H₂O by heating 12 hrs. on a H₂O bath; various salts. The 8-MeO deriv., m. 98°, results in 13% yields; various salts; *picrate*, Au-yellow, m. 153°. 8-EtO deriv., m. 98° (14.4% yield); *picrate*, Au-yellow, m. 182°. 2-Phenyl-4-methyl-8-quinolinecarboxylic acid, m. 201–2°, in 8.7% yield from *o*-HOCC₆H₄NH₂ HCl; various salts are described. 2-Phenyl-4-methyl-6-chloroquinoline, m. 91.5°, in 2.8% yield from *p*-ClC₆H₄NH₂ HCl; 6-Br deriv., m. 100° (3.8% yield); 6-I deriv., m. about 50° (yield, very poor). 6-Et deriv., m. 74° (15% yield). Various salts of these bases are described. 2-Phenyl-4-methyl-6-quinolinecarboxylic acid, m. 228° (5% yield). 2-Phenyl-4,5,8-trimethylquinoline, m. 111.5° (7.1% yield); the 4,5,6,8-tetramethylquinoline deriv., m. 128° (6.2% yield). 2-Phenyl-

4-methyl-6-[dimethylamino]quinoline, m. 131°; 2-Phenyl-4-methyl-8-hydroxy-naphthoquinoline (or the 3,1,9-deriv.), m. 107° (11.8% yield), from I and 2,7-H₂NC₁₀H₆OH. Various salts of all these are qual. described. C. J. WEST

β-Substituted o- and p-anisole- and phenetolesulfonquinaldines, their derivatives and their behavior towards nascent hydrogen. J. TRÖGER AND C. BROHM. *J. prakt. Chem.* **111**, 176-92(1925); cf. *C. A.* **17**, 2580.—β-(o)-Anisolesulfonquinaldine (I), m. 159°, from equiv. amts. of o-H₂NC₆H₄CHO and o-MeOC₆H₄SO₂CH₂Ac; *HCl* salt, needles, losing HCl at 105°; *nitrate*, decomps. 105°; *sulfate*, slightly yellow, decomps. about 200°; 4-sided prisms; *chloroplatinate*, Au yellow, decomps. about 230°. Reduction with Sn and HCl gives o-MeOC₆H₄SH and tetrahydroquinaldine. I and paraldehyde with ZnCl₂ give the *ethylidene deriv.*, m. 216°, whose side-chain is not oxidized by HNO₃. *Benzal deriv.*, m. 198°; *HCl* salt, yellow, slowly decomps. at 105°; reduction gives o-MeOC₆H₄SH and stilbazoline, C₆H₁₁NCH₂CH₂Ph. *Cinnamylidene deriv.*, yellow, m. 203°. *p-Anisolesulfonacetone*, m. 76.5° (oxime, m. 134°; *phenylhydrazone*, yellow-brown, m. 140°), with o-H₂NC₆H₄CHO this gives β(p)-anisolesulfonquinaldine, m. 122°; *HCl* salt, needles, slowly decomps. at 105°; *nitrate*, decomps. 105°; *sulfate*, decomps. 130°; *chloroaurate*, Au-yellow, decomps. about 105°. Reduction gives p-MeOC₆H₄SH and tetrahydroquinaldine. *The benzal compd.*, m. 200°; *cinnamylidene deriv.*, m. 149°. *o-Phenetolesulfonacetone*, m. 59° (oxime, m. 122°). β(o)-Phenetolesulfonquinaldine, m. 184°; *HCl* salt, m. 213° (decompn.); *nitrate*, decomps. 105°; *sulfate*, decomps. 186°; *chloroplatinate*, yellow, decomps. 178°. Reduction of the base gives o-EtOC₆H₄SH. *p-Phenetolesulfonacetone semicarbazone*, m. 179°. β(p)-Phenetolesulfonquinaldine, m. 113°; *HCl* salt, decomps. 105°; *nitrate*, darkens 105°, m. gradually at 135°; *sulfate*, m. 173° (decompn.); *HgCl₂ salt*, m. 155°. Reduction gives p-EtOC₆H₄SH. C. J. W.

Cyanine dyes. IX. The mechanism of the condensations of quinaldine alk-ioides in presence of bases. WM. H. MILLS AND RICHARD RAPER. *J. Chem. Soc.* **127**, 2466-75(1925); cf. *C. A.* **19**, 289.—This work was undertaken to support the theory of reaction proposed by M. and Smith (*C. A.* **17**, 1023). While the oils formed by the action of alkalis upon quinaldine alk-ioides could not be obtained pure, β-naphthoquinaldine-MeI and NaOH gave 1-methyl-2-methylene-1,2-dihydro-β-naphthoquinoline (I), bright yellow, gradually decomps. above 80°; on exposure to air, it becomes bright green, and even in vacuum it forms a tar within a few days. p-MeNC₆H₄CHO condenses with I, giving the *compd.* C₂₆H₂₂N₂ (II), scarlet; the 1:1 deriv. gave a similar *compd.* (III), C₂₆H₂₂N₂, scarlet powder. III and III in hot EtOH give p-dimethylaminobenzylidene β-naphthoquinaldine-EtI, m. 231-5°, also prepd. from β-naphthoquinaldine-EtI and p-MeNC₆H₄CHO. The methylene base (IV) from quinaldine-EtI and p-MeNC₆H₄CHO, treated with HI, give p-dimethylaminobenzylidenequinaldine-EtI, m. 247-8°, also synthesized as above. II and piperidine-III give the same green *compd.*, m. 237-9°, as is obtained by condensing the MeI salt and MeNC₆H₄CHO by piperidine. IV and PhCH₂I give quinaldine-EtI and dibenzylquinaldine-EtI (V), yellow, m. 214-6° (for synthesis see following abstract). Benzylquinaldine-EtI, yellow, m. 172-3°, by reducing the benzylidene *compd.* with HI or from benzylquinaldine and EtI; the anhydro base obtained with NaOH and Et₂O, treated with PhCH₂I, gave V. IV and p-toluquinaldine-EtI in EtOH contg. a little HCHO give 6-methyl-1,1'-diethylcarbocyanine iodide, which sensitizes a gelatino-bromide plate up to λ6950 for moderate exposures with a max. at λ6400 and λ5500. 5,6-Benzo-1,1'-diethylcarbocyanine bromide, needles with a green metallic luster, giving a blue EtOH soln.; it crystals with 1 mol. MeOH. The absorption shows a main band at λ6250 and 2 subsidiary bands at λ5750 and λ5350. C. J. W.

Dibenzylquinaldine. WM. H. MILLS AND A. T. AKERS. *J. Chem. Soc.* **127**, 2475-8(1925); cf. preceding abstr.—Dibenzylacetamide, m. 128-9°, in 30 g. yield from 40 g. acid through the chloride, gives with MeMgI as dibenzylacetone, b₁₆ 120-2°, BzH gives benzylidenedibenzylacetone, m. 66-7°; o-H₂NC₆H₄CHO gives 50% of dibenzylquinaldine, m. 74°, whose methiodide, yellow, m. 204° and EtI, m. 215-6°. In the prepn. of (PhCH₂)₂CHCOCl, if PCl₅ is used, or if the distn. with SOCl₂ is too slow, there results benzylhydrindone, whose semicarbazone, m. 198-9°. This also results by the reduction of the benzylidenhydrindone with Na-Hg in MeOH-EtOH. C. J. WEST

α-Phenyl-β-anisolesulfonquinoline and α-phenyl-β-phenetolesulfonquinoline. J. TRÖGER AND D. DIMITROFF. *J. prakt. Chem.* **111**, 193-206(1925).—α-Phenyl-β-(o)-anisolesulfonquinoline (I), m. 219°, from o-H₂NC₆H₄CHO and o-MeOC₆H₄SO₂CH₂COPh; *HCl* salt, yellowish, stable up to 160°; *nitrate*, decomps. at 105°; acid *sulfate*, stable at 160°; reduction gives o-MeOC₆H₄SH and tetrahydro-α-phenylquinoline (II), analyzed as the HCl salt. The methiodide of I, deep red, m. 206-8°. Ag₂O regenerates I. *p-Anisolesulfonacetophenone*, m. 110 (oxime, m. 134°; *phenylhydrazone*, m. 138°). *α-Phenyl-β(p)-anisolesulfonquinoline*, m. 187°; *HCl* salt, loses HCl at 125° and decomps.

at 155°; *nitrate*, m. 110° (decompn.); *acid sulfate*, begins to decomp. 170°. *Methiodide*, orange-yellow, m. 133-5°; moist Ag_2O regenerates the original base. Reduction of the base with Sn and HCl gives *p*- $\text{MeOC}_6\text{H}_4\text{SH}$ and II. *o*-Phenetolesulfonacetophenone, m. 99° (*oxime*, m. 129°; *phenylhydrazone*, m. 177°). α -Phenyl- β (*o*)-phenetolesulfonquinoline, yellowish, m. 174-5°; *HCl salt*, begins to decomp. 135°; *nitrate*, m. 110°, decomps. 145°; *acid sulfate*, decomps. about 170°. *Methiodide*, Au-yellow, m. 122°. Reduction with Sn and HCl gives *o*- $\text{EtOC}_6\text{H}_4\text{SH}$ and II. α -Phenyl- β (*p*)-phenetolesulfonquinoline, m. 153-4°; *HCl salt*, decomps. 105°; *nitrate*, decomps. 105°; *acid sulfate*, begins to decomp. 130°; *methiodide*, deep red, m. 169-70°. Reduction of the base gives *p*- $\text{EtOC}_6\text{H}_4\text{SH}$ and II.

C. J. WEST

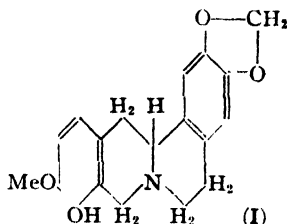

The action of alkalis on peptides and on ketopiperazines. P. A. LEVENE AND M. H. PFALTZ. *J. Gen. Physiol.* **8**, 182-8(1925).—"The tripeptide glycyl-*l*-alanlylglycine in soln. of either 1 or 10 equivs. of alkali does not undergo racemization on standing. The dipeptide *l*-alanlylglycine under the same conditions does not undergo racemization. In ketopiperazines, *l*-alanlylglycine anhydride and *l*-prolylglycine anhydride under the influence of dil. alkalis, racemization takes place. Racemization in the present expts. was never complete. The degree of racemization seems to depend, on the one hand, on the stability of the ketopiperazine ring; on the other, on the concn. of the alkali." Methods are given. Further work is in progress.

C. H. R

Further studies on demotropic forms of diketopiperazines and the formation of the latter and their combination with amino acids. EMIL ABDERHALDEN AND ERNST SCHWAB. *Z. physiol. Chem.* **149**, 298-301(1925); cf. *C. A.* **20**, 57.—"The tautomeric form of leucylglycine anhydride, m. 245°, was obtained by heating the ordinary anhydride with tyrosine in the presence of 10 parts of glycerol 5 hrs. at 190°, and extg. the reaction mixt. with CHCl_3 . It reacted with CH_2N_2 but the resulting Me ester could not be crystd. When leucylglycine anhydride and leucine were heated together with glycerol the products were leucineimide and leucyl[glycylleucine] anhydride or leucyl[leucylglycine] anhydride, m. 249°. By heating *dl*-leucine with glycine in glycerol the products obtained were leucineimide, 55% of leucylglycine anhydride, m. 238-9°, and a small amt. of glycine anhydride.

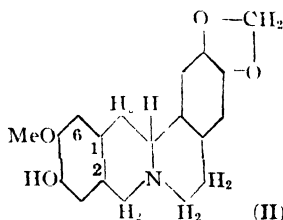

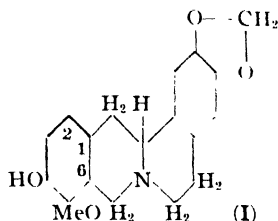

A. W. DOX

Alkaloid of *Nandina domestica*. I. The constitution of nandinine. Z. KITASATO. *J. Pharm. Soc. Japan* No. 522, 695-701(1925).—By an improved method of extn., a cryst. nandinine (I) was prepd. and its phys. properties and chem. compn. were detd. The bark of *Nandina domestica* was soaked in 50% alc., contg. 0.5-1% HCl, for a week. The residue was twice extd. with warm 95% alc. for 12 hrs. each. All the alc. exts. were concd., the resinous matter was removed by adding H_2O , and the free base was pptd. with NH_3 . The dried ppt. was then extd. with Et_2O , the ext. was shaken with 1% HCl and the Et_2O layer was sepd. On standing overnight colorless needles were obtained. The pure I thus prepd. has the compn. $\text{C}_{19}\text{H}_{19}\text{NO}_4$, confirming the result of Eykman's analysis of amorphous nandinine (*Ber.* **1884**, 441). It m. 145-6°, has $[\alpha]_D^{20}$ 63.2° (alc.), and has one MeO and phenolic OH. The preliminary study of the chem. nature of I suggests that it has OH in place of one MeO of tetrahydroberberine. When I is methylated with CH_2N_2 it gives a substance m. 138-9°, having no phenolic OH, which was identified as the *d*-canadine of Gadamer (*C. A.* **5**, 2078). In order to det. the position of the OH and MeO in I, the HCl salt of berberine was fused with urea, to remove the chloromethyl group, and K. obtained the berberrubine of Frerichs (*C. A.* **4**, 2443). When this was reduced to hydroberberrubine, and optical sepn. using *d*-bromocamphorsulfonic acid (NH_4 salt) was applied, *d*-hydroberberrubine which is identical with I, was obtained. The conclusion is that I is *d*-hydroberberrubine, i. e., the MeO at position 5 of tetrahydroberberine is substituted by OH. The constitution of I therefore, must be as follows:

From the residue of the final Et_2O extn., K. obtained a new alkaloid, nandazurine, m. 350°, the chem. compn. of which will be reported later. II. **Synthesis of inactive**

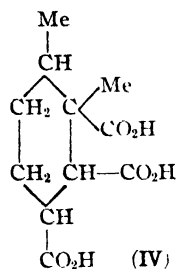

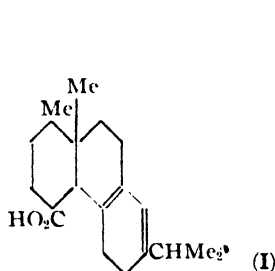

ψ -nandinine. *Ibid* No. 523, 791–8.—Since nandinine is *d*-hydroberberubine, K. expected that by the method of Pictet and Gams (*Ber.* 44, 2480(1911); cf. *C. A.* 5, 3413), of synthesizing berberine, using vanillin, a synthesis of an isomer of nandinine (I) should be easy. However, in an attempt to put in CH_2 between the vanillyl ring and the imino group, by treating 1-vanillyl-6,7-methylenedioxytetrahydroisoquinoline and HCHO , the chain closed at position 2 instead of at 6, giving therefore II. Since Perkin, Jr (*C. A.* 1686(1924)), obtained similarly ψ -tetrahydroberberine in an attempt to repeat P. and G.'s synthesis of berberine, K names this new compd ψ -nandinine. It m. 181° , and is identified by its easy conversion to the ψ -tetrahydroberberine, m. 177° , of P.

S T

Polarity theories and four-membered rings. The non-existence of 2,3,3-triphenyl-methylene-1,2-oxamine. G. N. BURKHARDT, ARTHUR LAPWORTH AND JAMES WALKER. *J. Chem. Soc.* 127, 2458–61(1925).—Ingold and Weaver (*C. A.* 18, 3193) state that PhNO and $\text{Ph}_2\text{C}:\text{CH}_2$ give rise to 2,3,3-triphenylmethylene-1,2-oxamine, this compd. is now shown to be $\text{Ph}_2\text{C}:\text{NPh}:\text{O}$ (Angeli, Alessandri and Aiazzi Monum. *C. A.* 5, 3403). Thus, such facts as have been fully established are in complete harmony with Robinson's theory of polar reactions of PhNO and in general with electrochem conceptions of org. chem. reactions. C J WEST

Higher terpene derivatives. XXV. Anhydride formation and nitric acid oxidation of abietic acid. L. RUZICKA AND M. PFEIFFER. *Helvetica Chim. Acta* 8, 632–6(1925). Exception is taken to Knecht's claim (*C. A.* 18, 759) that abietic acids (I), heated to 180° , undergo anhydride formation. Expts. are given showing that I from 2 different sources is mainly unchanged under these conditions, and that part of the loss consists not only of H_2O , as K. assumed, but also CO_2 and oils. The hydrocarbons remaining in the residue can give C and H values approximating those of the anhydride. By essentially the method used by Virtanen (*C. A.* 15, 3096), who reported that oxidation of I with HNO_3 yields no 1,2,5- $\text{C}_6\text{H}_3(\text{CO}_2\text{H})_3$ (II), a 10% yield of pure II was easily obtained from I from American colophony, this being in agreement with the formula

for I (cf. also R. and Meyer, *C. A.* 16, 3893; R., Schinz and M. *C. A.* 18, 681). **XXVI. Degradation of abietic acid with potassium permanganate and ozone.** L. RUZICKA, J. MEYER AND M. PFEIFFER. *Ibid* 637–50.—Oxidation of I (prepd. according to *C. A.* 16, 2500) in 1% aq. KOH with KMnO_4 (10 atoms O), with gentle warming toward the end, gave no ppt. with CO_2 , but yielded an amorphous mixt. with HOAc, corresponding roughly to $\text{C}_{16}\text{H}_{22}\text{O}_4$ and $\text{C}_{17}\text{H}_{24}\text{O}_4$, similar to Aschan's "colophenic acids" (*C. A.* 15, 3097); that a keto acid is present is shown by the isolation of an amorphous semicarbazone, m. 225° (decomn.). An attempt to sep. the Me esters of these acids by fractional distn. yielded no definite results as almost all b.p.s. $200\text{--}10^\circ$; after sapon. of the esters the amorphous semicarbazones m. ca. 240° , that of the last fraction corresponding to the acid $\text{C}_{16}\text{H}_{22}\text{O}_4$. After removal of the above acids the soln. was made alk. and concd., filtered from a small additional ppt. on adding HCl, and extd. with Et_2O .

The residue, heated in a high vacuum at 105°, and the distillate treated with SOCl_2 and PhNH_2 , yielded $\text{Me}_2\text{CHCONHPh}$ (III). A similar Et_2O ext., unheated, slowly deposited (> 1 yr.) an acid, possibly (IV), $\text{C}_{11}\text{H}_{16}\text{O}_6$, m. 224°; tri-Me ester (V), from the Ag salt, m. 75°, rhombs, $a:b:c = 0.8289:1:0.9620$. Oxidation of I during 1 month with KMnO_4 (24 atoms O), repeatedly heating at 30° toward the end, gave an Et_2O ext. as above from which $(\text{CH}_3\text{CO}_2\text{H})_2$ sepd. The portion of the Me esters of the remaining acids (several % of the I taken), b_{12} 100–80°, taken up in concd. HCl, deposited V. Oxidation of I Me ester (VI) in aq. MeAc with KMnO_4 (6 atoms O) and MgSO_4 , cooling with ice, evapd. the MeAc *in vacuo*, taking up in Et_2O , and extg. with dil. NaOH, gave a small amt. of acid products which were not investigated. The neutral portion, corresponding to the Me esters of the above "colophenic acids," b_2 225–35°, both the 1st and last fractions corresponding to $\text{C}_{21}\text{H}_{30}\text{O}_4$; when sapond. the amorphous semicarbazone m. ca. 225° (decompn.); the acid(s) $\text{C}_{20}\text{H}_{20}\text{O}_4$ lose(s) H_2O when boiled 15 hrs with Ac_2O and NaOAc, then giving an amorphous semicarbazone decomp. ca. 240°. Ozonization of I in CCl_4 yielded chiefly ill-defined split-products, including semicarbazones decomp. ca. 225° and 260°; V was also isolated. Similarly VI yielded neutral and acid products; the latter giving (di)-Me esters, b_1 195–210°, corresponding roughly to $\text{C}_{18}\text{H}_{28}\text{O}_6$. Ozonization of VI in HOAc, followed by heating first to 100° and then to 110°, followed by another ozonization for 4 days and heating again, yielded chiefly oily acids sol. in dil. Na_2CO_3 . Repeated treatment of the Ag salts with MeI and fractionation gave esters approximating to $\text{C}_{15}\text{H}_{24}\text{O}_6$, $b_{0.6}$ 132–7°, and $\text{C}_{18}\text{H}_{28}\text{O}_6$, $b_{0.6}$ 203–5°. The fractions, $b_{0.6}$ 125–55°, treated with HCl, deposited leaflets, but the whole was heated at 100° and the HCl then evapd. off, finally depositing a cryst. acid, $\text{C}_{17}\text{H}_{16}\text{O}_6$, m. 215–6°, apparently a homolog of IV; when reconverted into the Me ester over the Ag salt crystals were not obtained. Full details of the oxidations are given

M. HEIDELBERGER

The homogeneity of α -lignin. E. HAGGLUND. *Biochem. Z.* **158**, 350–6 (1925).—Spent sulfite liquors were boiled 13, 15, 17, 18 and 20 hrs. and α -lignosulfonic acids pptd. from each fraction by β - $\text{C}_{10}\text{H}_7\text{NH}_2$. Analysis of these fractions indicated that α -lignin is homogeneous.

F. A. CAJORI

Lignin. I. WILLIAM KÜSTER AND E. SCHNITZLER. *Z. physiol. Chem.* **149**, 150–72 (1925).—Assuming that lignin is an individual substance, the evidence of these expts. indicates that the mol. is built up of 2 distinct parts, 1 of which is present in preponderant amt. Hence the mol. may be regarded as built up of a high and a low mol. constituent in equal proportions or else as a simpler nucleus condensed with several mols. of the other substance. The method consisted in fusing pine sawdust, from which the resin had been removed, with 2 parts of β -naphthol at 180–200°. The melt was dissolved in CHCl_3 and a 1st reaction product, m. 155° (decompn.), pptd. by Et_2O . From the filtrate a 2nd product, m. 160–8° (decompn.), was pptd. by petroleum ether. The mother liquor yielded a cryst. substance $\text{C}_{22}\text{H}_{14}\text{O}$, m. 205–6°, for which the name *merolignin* is proposed. The yield of this is 10% of the original lignin. The total wt. of the 3 products is equiv. to that of the lignin, although gaseous products also are formed, among which H_2O , CO_2 and MeOH were identified, hence it is inferred that part of the β -naphthol enters into the reaction. A 2nd fusion converts the 1st product into the 2nd, but no further yield of merolignin is thus obtained. This product is amorphous, contains MeO and has the empirical formula $\text{C}_{18}\text{H}_{13}\text{O}_3\text{OMe}$. The merolignin may be extd. along with the β -naphthol by benzene, and its solns. show intense blue fluorescence. The O must be in oxide form, since the empirical formula excludes aliphatic OH, the substance is neutral, and aldehyde and ketone groups could not be demonstrated. Bromination of merolignin in CHCl_3 gives a gold-red cryst. product $\text{C}_{21}\text{H}_{14}\text{Br}$, m. 267° (decompn.). Concd. HNO_3 converts merolignin into a dark red cryst. substance $\text{C}_{18}\text{H}_{11}\text{O}_3\text{N}$, m. 203°. It appears that merolignin possesses a benzenoid structure which readily passes into the quinonoid form and then undergoes further changes. It shows certain resemblances to the resin acids which are regarded as phenanthrene derivs. The m. p. is the same as that of p - $\text{Ph}_2\text{C}_6\text{H}_4$, but a comparison of the 2 substances showed that they are not identical. In contrast to lignin, cellulose does not dissolve in β -naphthol under the conditions of these expts.

A. W. DOX

Partial bromination of phlorhizin. I. KEIZO MISAKI. *J. Biochem. (Japan)* **5**, 1–7 (1925).—A dibromophlorhizin is obtained when crystd. phlorhizin in H_2O -free MeOH is carefully treated with Br water at -5° to -10° . It has $[\alpha]_D -35.8^\circ$, m. 160° and has the compn. $\text{C}_{21}\text{H}_{27}\text{O}_{10}\text{Br}_2$. When shaken with H_2O and ether to which Br_2 is added slowly, the excess of Br_2 being removed by repeated shaking with ether until it remains colorless, it gives hexabromophloretin and glucose. II. **Bromophlorin and bromo- p -hydroxyphenylpropionic acid, cleavage products of dibromophlorhizin.**

Ibid 9-12.—Six g. dibromophlorhizin in 80 cc. 12.5% Ba(OH)₂ is refluxed on a water bath for 9 hrs. The mixt. is acidified to Congo red with dil. H₂SO₄, filtered and the filtrate is extd. repeatedly with ether. On evapg. the ether crystals are obtained which sep. from hot water in prismatic plates which give the Br flame test, m. 90°, and dissolve readily in Na₂CO₃ with liberation of CO₂. Its compn. shows it to be monobromo-*p*-hydroxyphenylpropionic acid. The liquid which remained after the ether extn. has been shown to contain bromophlorin and bromophloretinic acid, which are thus to be regarded as products of the Ba(OH)₂ hydrolysis of the dibromophlorhizin. S. M.

Remarks on the communication of Stefan Goldschmidt and Christian Steigerwald: degradation of proteins by hypobromite. EMIL ABDERHALDEN. *Ber.* 58B, 1821-2 (1925).—A. complains that his work and that of his pupils is slighted in the paper of G. and S. (*C. A.* 19, 1084). C. A. R.

SCHMIDT, JULIUS: *Jahrbuch der Organischen Chemie*, 1924. 11th ed., revised. Stuttgart: Wissenschaftliche Verlagsgesellschaft, 285 pp., paper G. M. 22; bound G. M. 25. Reviewed in *Chemistry & Industry* 44, 800(1925).

Methylal. C. B. CARTER. U. S. 1,566,819, Dec. 22. Methylene chloride, NaOH and MeOH are heated together in an autoclave to about 100-125° to produce methylal, which may then be hydrolyzed and distd. to obtain formaldehyde. Similar reactions may be carried out with EtOH, PrOH and BuOH.

Hexamethylenetetramine. C. B. CARTER. U. S. 1,566,820, Dec. 22. In the production of pure (CH₂)₆N₄ from crude mixts. contg. it, NH₃ is introduced into a solu. of (CH₂)₆N₄ to lower the satn. point and cause pptn. of the (CH₂)₆N₄.

Separating hexamethylenetetramine from ammonium chloride. C. B. CARTER. U. S. 1,566,822, Dec. 22. Methylene chloride and aq. NH₃ are heated and excess NH₃ is employed to lower the solvent power of the liquor for (CH₂)₆N₄ and increase it for NH₄Cl. Pptd. (CH₂)₆N₄ is sepd. from the liquor. NH₃ is distd. from it and the remaining liquor is then cooled and NH₄Cl, which ppts., is sepd.

Separating hexamethylenetetramine from ammonium chloride. C. B. CARTER. U. S. 1,566,821, Dec. 22. A strong aq. NH₃ solu. is used which has a selectively greater solvent power for NH₄Cl than for (CH₂)₆N₄.

"Derivatives of hypothetical imines," etc. K. F. SCHMIDT. U. S. 1,564,631, Dec. 8. In forming PhNH₂, *p*-xylydine or various "derivs. of hypothetical imines including amiaes and their substitution products." C₆H₆, *p*-xylene or other "org. compds. of the hydrocarbon type" are treated with hydrazoic acid in the presence of concd. mineral acids, to effect direct introduction of NH₂.

4-Nitro-1-acetonaphthalide-6 (or 7)-sulfonic acid. W. M. RALPH. U. S. 1,566,425, Dec. 22. In producing "nitro-acetyl-Cleve's acid," "acetyl-Cleve's acid" in solu. in H₂SO₄ is subjected to nitration and the resulting nitroacetyl acid is isolated in the form of its Na salt by adding the nitration mixt. to Na₂CO₃ and H₂O to effect neutralization and salting out by the action of the Na₂SO₄ formed.

Sodium salts of aromatic sulfonic acids. H. W. HILLYER. U. S. 1,546,239, Dec. 8. A solu. contg. a Ca salt of a sulfonic acid, *e. g.*, of nitrochlorobenzenesulfonic acid, is treated with NaCl to effect formation and pptn. of the corresponding Na salt.

Indoxyl. H. H. DOW. U. S. 1,564,218, Dec. 8. In making indoxyl or its derivs., a phenylglycine material intermixed in a caustic alkali melt is also treated with a hydrocarbon oil, *e. g.*, kerosene, which is vaporizable at a temp. between that at which the caustic alkali is molten and that at which decompn. of the phenylglycine material tends to occur. This assists in control of the reaction.

***m*-Amino-*p*-cresol methyl ether.** C. G. DERRICK, T. H. LEAMING and W. M. RALPH. U. S. 1,564,214 Dec. 8. *m*-Nitro-*p*-cresol is methylated in the presence of an excess of NaOH and the resulting mixt., while still hot, is subjected to reduction by adding Na sulfide, in the presence of H₂O.

Acyated alkylenediamines. M. HARTMANN and J. KAGI. U. S. 1,534,525, April 21, 1925. By the reaction of an acid halide or anhydride on unsymmetrical substituted alkylenediamines, preferably in H_2O or other solvent and in some cases in the presence also of an alkali, there is obtained in quant. yield a monoacyl or an unsymmetrical diacyl deriv. Unsym. diethylethylenediamine yields a monoacetyl deriv. which is a yellowish oil, b_p 137–8°. The linoleic acid deriv. is a thick oil insol. in H_2O but sol. in org. solvents. Distearylethylenediamine, monostearylethylenediamine, di- and mono-oleylethylenediamines, mixed derivs. from olive oil and propylenediamine hydrate, oleylpiperidyl-*N*-ethylamine, stearyldimethylethylenediamine (m. 71°), oleylphenylethylenediamine, oleyldiethylethylenediamine and the hydrochloride and tartrate of the latter are described. These compds. are applicable for technical and therapeutic purposes.

Alcohols from monohalogenated hydrocarbons. C. B. CARTER and A. E. COXE. U. S. 1,566,818, Dec. 22. In effecting reaction between CH_3Cl or other monohalogenated hydrocarbon deriv. and alkali such as $NaOH$, a temp. of about 100° is employed and the reaction is carried out under pressure, the alc. produced being removed from time to time to maintain an alc. concn. below 20% in the reaction vessel.

Methanol and methylene chloride from methane. J. WEBER and P. ERASMUS. U. S. 1,565,345, Dec. 15. Gaseous $MeCl$ is caused to react with milk of lime under the action of heat and pressure. $MeCl$ admixed with CH_2Cl_2 is used and unabsorbed gas comprising CH_3Cl_2 is withdrawn from the reaction chamber.

ω -Haloalkyl arsonocarbaniates. R. ADAMS and C. W. RODEWALD. Can. 254,983, Oct. 27, 1925. An arsanilic acid or a substituted arsanilic acid is treated with an alkali and an ω -haloalkyl halocarbonate. The product is acidified and allowed to crystallize.

Styrene and its homologs. I. OSTROMISLENSKY and M. G. SHEPARD. U. S. 1,511,175, June 9, 1925. Styrene and its homologs are produced from hydrocarbons having 8 or more C atoms such as ethylbenzene, xylene, homologs and analogs, by pyrogenic decompn. Temps. of about 450–700° are employed. U. S. 1,541,176 (I. OSTROMISLENSKY) specifies manuf. of styrene by dropping melted cinnamic acid into a receiving chamber at normal pressure heated to 295–8°, decomposing the cinnamic acid to form styrene, conducting the vapors of the styrene away from undecomposed cinnamic acid, condensing and purifying by steam distn. and fractionation.

Hydrochloride of 3,3'-diamino-4,4'-dihydroxyarsenobenzene. P. A. KOBER. U. S. 1,564,860, Dec. 8. A purified 3,3'-diamino-4,4'-dihydroxyarsenobenzene is dissolved in HCl in such amt. that no free uncombined HCl remains in the resulting soln. is evapd. to dryness under a pressure of 2–10 mm. Hg.

Synthesizing aldehydes, acids or similar compounds. G. WIETZEL and R. WIETZEL. U. S. 1,562,480, Nov. 24. In synthesizing higher ales., aldehydes, acids or similar higher mol. compds. contg. O, CO is caused to act on vaporized $MeOH$, $EtOH$ or other vaporized aliphatic alc. at an elevated pressure and temp., *e. g.*, 200 atm. and 420°, and in the presence of a catalyst, *e. g.*, one contg. alkali, Cr and Mo.

Compounds of halogen acids with 2-phenyl-6-methylquinoline-4-carboxylic acid and its esters. H. W. RHODEHAMEL and E. H. STUART. U. S. 1,552,568, Sept. 8, 1925. 2-Phenyl-6-methylquinoline-4-carboxylic acid hydriodide forms orange yellow crystals, m. 268.5°. The hydrobromide and hydrochloride, m. 289° and 254.5°, resp. The hydriodide of the *Et* ester, m. 177° and the corresponding hydrobromide, hydrochloride and hydrofluoride, m. 176°, 171° and 170–172°, resp. The hydrobromide, hydrochloride and hydriodide of the *Pr* ester, m. 170°, 148° and 164°, resp. and the corresponding compds. of the normal butyl ester, m. 123–6°, 118° and 158°, resp. These compds. may be prepd. by treating 2-phenyl-6-methylquinoline-4-carboxylic acid or one of its esters with a halogen acid, preferably in excess, and then drying; or, by dissolving the 2-phenyl-6-methylquinoline-4-carboxylic acid or an ester in alc., acetone or other org. solvent and adding a mol. proportion of the halogen acid. The halogen acid compd. crystallizes and is filtered off and dried.

2-Aminoanthraquinone. O. D. CUNNINGHAM. U. S. 1,564,210, Dec. 8. Anthraquinone-2-sulfonic acid is subjected to the action of aq. NH_3 soln. in the presence of a sol. Ba salt, *e. g.*, $BaCl_2$, and of NH_4Cl , at a temp. of about 150–200°.

Amino derivatives of anthraquinone, etc. H. A. E. DRESCHER and J. THOMAS. U. S. 1,528,470, March 3, 1925. Halogen derivs. of anthraquinone are treated with an imide of a dibasic acid such as phthalimide in the presence of Cu and an acid absorber, *e. g.*, $NaOAc$, at temps. usually about 200°, in order to eliminate the halogen in the form of an acid and form another deriv. from the anthraquinone and the imide. By treating this product, *e. g.*, with H_2SO_4 , the dibasic acid may be regenerated and an amino deriv. of anthraquinone formed. Numerous examples are given, including production of 1-

phthalimidoanthraquinone from 1-chloroanthraquinone and its conversion into 1-aminoanthraquinone, production of 1,5-diphthalimidoanthraquinone and its conversion into 1,5-diaminoanthraquinone, production of 1-chloro-5-phthalimidoanthraquinone from 1,5-dichloroanthraquinone and its conversion into 1-chloro-5-aminoanthraquinone, production of 1-phthalimido-2-nitroanthraquinone from 1-chloro-2-nitroanthraquinone and its conversion into 1-amino-2-nitroanthraquinone, production of 1-amino-2-methyl-4-phthalimidoanthraquinone from 1-amino-2-methyl-4-bromoanthraquinone and its conversion into diamino-2-methylantraquinone, production of 1-methylamino-4-phthalimidoanthraquinone from 1-methylamino-4-bromoanthraquinone and its conversion into 1-methylamino-4-aminoanthraquinone, production of 1-phthalimido-2-aminoanthraquinone from 1-chloro-2-aminoanthraquinone and its conversion into 1,2-diaminoanthraquinone, production of 2-phthalimidoanthraquinone from 2-bromoanthraquinone and its conversion into 2-aminoanthraquinone, production of 1-succinimidoanthraquinone from 1-chloroanthraquinone. PhNO_2 may be used as a vehicle for the reaction.

1-Phthalimidoanthraquinone and similar compounds. H. A. E. DRESCHER and J. THOMAS. U. S. 1,528,470, March 3, 1925. Halogen compds. of anthraquinone, *e. g.* 1-chloro-, 1,8- or 1,5-dichloro-, 1-chloro-2(or 4)-nitro-, 1-amino-2-methyl-4-bromo-, 1-methylamino-4-bromo-, 1-chloro-2-amino-, or 2-bromoanthraquinone, are treated with an imide of a dibasic acid such as phthalimide, in the presence of Cu and an acid absorber, *e. g.*, NaOAc, at elevated temps. (generally 180–200°), to eliminate halogen in the form of an acid and form 1-phthalimidoanthraquinone or a similar deriv. The latter can be treated with an acid such as H_2SO_4 to regenerate the dibasic acid and form an amino deriv. of anthraquinone. Numerous examples are given.

Diphenylamine chloroarsine. W. L. TANNER. U. S. 1,557,384, Oct. 13. A mixt. of As_2O_3 and diphenylamine-HCl is heated.

Apparatus for chlorinating naphthalene, etc. S. BROWN. U. S. 1,546,044, Dec. 1.

FRANK P. UNDERHILL

Collagenous fibrils—their origin, structure, and arrangement. G. C. HERINGA and H. A. LOHR. *Proc. Acad. Sci. Amsterdam* 28, 509–17(1925).—The prepn. of histological specimens by paraffin or celloidin imbedding results in the destruction of the connective tissue—a result not obtained when the gelatin freezing method is used. A study of the collagenous fibrils in specimens of the umbilical cord and skin by the latter method caused H. and L. to conclude that the fibrils in the interstitial substance originate from needle-shaped ultramicros present in that area; that the interstitial substance does not induce the formation of fibrils everywhere to the same extent, that the cells exert no influence on the course of the fibrils and the tendency of the fibrils to form a sinuous course and close tapelike complexes is caused by physical properties of the fibrils themselves. A hypothesis to explain the behavior of the fibrils based on colloid chemistry is given.

Biocatalysts and carbohydrate metabolism. III. HANS V. EULER and KARL MYRBÄCK. *Z. physiol. Chem.* 150, 1–15(1925); cf. *C. A.* 20, 70—Pancreatic insulin has no sp. influence on the fermentation velocity of bottom yeast H. Expts. without accurately controlled acidity and PO_4 content are not conclusive. Cozymase is not replaceable by pancreatic insulin. Insulin-free cozymase is a sp. activator for phosphatase, and hence may be considered the coenzyme of phosphatase. This, however, does not exclude the possibility that insulin may in some way be concerned in the phosphate exchange of sugars, though at present no evidence of this is available. Ester-

ification of hexoses (formation of zymophosphate) by chopped muscle in the absence of O is not appreciably activated by pancreatic insulin.

A. W. DOX

The natural porphyrins. XVIII. Chemical findings in a case of porphyrinuria (Petty). HANS FISCHER, HANS HILMER, FRITZ LINDNER AND BRUNO PÜTZER. *Z. physiol. Chem.* **150**, 44-101(1925); cf. *C. A.* **20**, 57—The porphyrin patient, Petty, whose urine and feces had furnished most of the material for the investigations described in this series of papers, died Jan. 21, 1925. After the autopsy, which revealed a great variety of pathological conditions, the sep. organs were subjected to chem. treatment for the isolation and identification of the porphyrins contained there in. The skeleton was found to be highly pigmented, and the porphyrin present was identified as uroporphyrin, while coproporphyrin was absent. This selective pigmentation is significant. The bone marrow, contd. both porphyrins and probably also Kämmerer's porphyrin. Coproporphyrin was found in the blood but no uroporphyrin was present. The spleen, which was much enlarged, contd. an abundance of coproporphyrin, while uroporphyrin predominated in the liver and kidneys. Although the skin was mahogany-brown no porphyrin could be demonstrated. The bile was normal with respect to bile pigments but contd. a large amt. of coproporphyrin.

A. W. DOX

The elementary composition of hair. ZDENKO STARY. *Z. physiol. Chem.* **150**, 202-4(1925).—Detns. of C, H and N on a no. of samples of human hair gave results in agreement with those reported in the older literature, but not in agreement with those of Rutherford and Hawk (*C. A.* **1**, 1298) even when the samples received the same preliminary treatment

A. W. DOX

Glutathione. Its influence in the oxidation of fats and proteins. J. G. HOPKINS. *Biochem. J.* **19**, 787-819(1925).—H. used muscle tissue almost exclusively, and the estns. of uptake were made in the Barcroft "differential manometer." In aq. systems contg. GSH (reduced or thiol form of glutathione) together with an emulsion of unsatd. fatty acids (linolenic, linoleic) or lecithin, so long as the p_H is 3.4-4, the concn. of the SH group is long maintained, and O many times in excess of what is required to oxidize the SH to S-S is taken up, a corresponding amt. of the fatty acid or lecithin being oxidized. H. agrees with Meyerhof's mechanism of oxidations for such systems (*C. A.* **18**, 2349): the preliminary formation of a peroxide by 2 thiol groups; and the decompn. of the peroxide, the O being transferred to the unsatd. linkages of the fatty acids while the original SH groups are reconstituted. Here the thiol group is concerned essentially with O transport. At p_H 7.4-7.6, the system $GSH + \text{unsatd. fatty acid}$ behaves differently; here the O uptake is equal to the amt. of O required to oxidize the SH. The SH group is no longer an O carrier in the sense that Meyerhof postulated for acid systems, but its case probably becomes one represented by $AO_2 + B \longrightarrow AO + BO$, where A is an autoxidator and B an acceptor. During the oxidation of the SH group fatty acids are simultaneously oxidized in such a way that equipartition of O occurs. Neither in acid nor in slightly alk. systems do fats behave as do the fatty acids. In an acid system, for a period of 1-3 hrs., the oxidation is slow, but then becomes quite rapid; in an alk. system, there is a rapid oxidation, falling off somewhat after the second hr. Proteins are oxidized by glutathione (GSH or the oxidized form, G_2S_2) provided the protein itself displays an SH group (as shown by the nitroprusside reaction). Proteins of water-extd. muscle contain the SH group and are oxidized in neutral and faintly alk. but not in acid (p_H 3.0-4.5) solns. The protein SH is oxidized and the nitroprusside reaction disappears, while the total O taken up amounts to 10 times the O equiv. of the SH. The oxidized protein can again be reduced by contact with glutathione (GSH), cysteine or thioglycolic acid; it now responds to the nitroprusside test, and, in the presence of glutathione, again takes up O much in excess of the O equiv. of the SH. In contrast to the proteins of water-extd. muscle, the proteins from blood serum must first be denatured before they exhibit oxidation-reduction reactions. H. does not overlook the fact that Fe may play a part in these oxidations (see Warburg and Sakuma, *C. A.* **18**, 845). "The metal [Fe] is only another link in the chain . . . none of the results to which significance is attached in this paper is due to the direct influence of Fe alone."

BENJAMIN HARROW

Factors influencing the action of pancreatic lipase. B. S. PLATT AND E. R. DAWSON. *Biochem. J.* **19**, 860-74(1925).—The enzyme was prepd. either according to the method of Umeda (*C. A.* **9**, 1789) or to that of Willstätter (*C. A.* **18**, 2718). The lipase was detd. by estg. the amt. of acid liberated from Et butyrate or from olive oil (see Willstätter (*C. A.* **18**, 2718)). The optimum p_H of lipase obtained from a purified pancreas powder, if borax-boric acid buffer solns. are used, is 8.4, and if phosphate-borax buffer solns. are used, 7.0. Lipase does not promote hydrolysis of Et butyrate

in the absence of activators. Phosphates are necessary for the complete activation of lipase. The results suggest that the protein structure which has been ascribed to lipase is characteristic of the substances associated with the enzyme rather than of the enzyme itself. The ester-hydrolyzing properties of the enzyme have been definitely altered by changing the accompanying protein. The apparent destruction of lipase by trypsin is due, in part, to the removal by hydrolysis of proteins which activate the lipase.

BENJAMIN HARROW

The present situation of the problem of plasma structure. JOSEF SPEK. *Naturwissenschaften* 13, 893-900(1925).—A review.

R. J. C. VAN DER HOEVEN

Examination of an adipocere cadaver. GEORG STRASSMANN AND FANTL. *Deut. Z. ges. ger. Med.* 6, 168-74(1925).—The appearance of the corpse is described. Chem. analysis of samples gave the following results: ether-sol. portion 82.16, ash 4.03, water 1.22%. Cholesterol was very small in quantity. The ether-sol. fraction showed an acid no. 207.75, sapon. no. 238.85, ester no. 31.10 and an I no. 8.18. F. K.

Gas formation in the heart of the cadaver. LADISLAV JANKOVIC. *Deut. Z. ges. ger. Med.* 6, 379-80(1925).—J. shows that in his climate diagnosis of air embolism is possible only when the cadaver is opened within 2 days after death. Beyond this period putrefaction sets in and various gases are elaborated.

FRANCES KRASNOW

Osmosis of some anesthetics in water and lipid-containing gels. S. YUMIKURA. *Biochem. Z.* 157, 359-70(1925); cf. *C. A.* 19, 2435.—The rate of diffusion into gelatin of cocaine, novocaine, tutocaine, alypine and eucaine is detd. in the presence of lecithin both with and without alkali. Since alypine and eucaine diffuse into the gel most rapidly, and are also most toxic, this toxicity is then a function of the rate of diffusion. In the presence of lecithin, cocaine diffuses most rapidly. As higher animals have more lipid material than lower animals, the greater toxicity of cocaine in this case is to be expected.

W. D. L.

Osmosis in aqueous gel with and without addition of lipid. S. YUMIKURA. *Biochem. Z.* 157, 371-6(1925); cf. preceding abstract.—By using various amts. of lecithin in gelatin gels, it is found that the rate of diffusion of surface-active substances, such as caprylic acid and octyl alc., increases with increase of lecithin. With substances of smaller surface activity, e. g., butyric acid and isoamyl alc., smaller differences are noted.

W. D. L.

Osmosis of some acids into gelatin. S. YUMIKURA. *Biochem. Z.* 157, 377-82(1925); cf. preceding abstract.—The rates of diffusion of the surface-inactive H_2SO_4 , HCl, lactic and formic acids at various concns. are compared. The acids arrange themselves in the series $\text{HCl} > \text{H}_2\text{SO}_4 > \text{HCO}_2\text{H} > \text{CH}_3\text{CH}(\text{OH})\text{COOH}$.

W. D. L.

Lipoid theory and surface activity theory. II. I. TRAUBE AND S. YUMIKURA. *Biochem. Z.* 157, 383-7(1925); cf. preceding abstracts.—This is a discussion of the possible correlation of the facts in the above abstracts to diffusion phenomena in plants and animal tissues.

W. D. L.

Preparation, solubility, and specific rotation of wheat gliadin. D. B. DILL AND C. L. ALSBERG. *J. Biol. Chem.* 65, 279-304(1925); cf. *C. A.* 19, 3479, 3503.—Preps. of gliadin have been obtained contg. 17.54% of N and with an exceedingly low av. ash content of 0.08%. The pptn. in aq. soln. was made with vigorous shaking as the gliadin is pptd. as a foam which can be thoroughly washed; LiCl instead of NaCl was used to promote pptn. as it is sol. in alc. and Et_2O . Gliadin is irreversibly altered by standing in contact with 75-85% alc. but the temp. and condition of the gliadin, whether dry or moist, are important variables. Heretofore it has been assumed that gliadin is not altered by any concn. of alc.; hence this finding is quite significant in connection with its detn. in flour. Cooling of a soln. of gliadin in alc.- H_2O results in the production of a turbidity at a definite temp. which varies with the % of alc. but is practically independent of the concn. of the gliadin. This temp. is, therefore, called a crit. peptization temp. There appears to be no upper limit to the soly. of gliadin in Me, Et and *n*-Pr alc.- H_2O mixts. above the crit. temp., as it readily forms concn. (20%) solns. in 10% EtOH at 50° and is peptized in 80% alc. at 31°. It is peptized at room temp. (20°) in solvents contg. approx. 35-77% of alc. It is also sol. in solns. of KSCN, NH_4SCN , KI, urea, chloral hydrate, glycerol, ethylene glycol, the propylene glycols, mixts. of glycerol and abs. alc. contg. over 25% of glycerol, and in 10-25% solns. of Me-Et ketone. With solvents contg. 70, 60 and 50% of EtOH by vol., $[\alpha]_D^{20}$ was -89.8, -91.0, and -90.3°, resp., values from 1 to 2° lower than most values in the literature. These values increased considerably over a temp. range of 20-50°. In *n*-Pr alc.- H_2O $[\alpha]_D^{20}$ averaged -98.2° and did not vary significantly with the proportion of H_2O . In 30% aq. urea soln. $[\alpha]_D^{20}$ was -116.5°. No racemization occurred

on heating this soln. at 37° for 7 days; hence the formation by urea and gliadin of an alkali albuminate seemed unlikely.

A. P. LOTHROP

A further investigation of the chemical properties of insulin. D. A. SCOTT. *J. Biol. Chem.* **65**, 601-16(1925); cf. *C. A.* **19**, 2059.—The chem. properties have been studied of a very pure insulin product having a physiol. assay of 25,000 units per g. of powder and a N content of 0.006 mg. per unit of activity. The essential steps in the prepn. were extn. with HCl-alc.; pptn. of the concentrate with $(\text{NH}_4)_2\text{SO}_4$; dissolving the ppt. and repptg. in warm alc.; fractional pptn. at different acidities; and pptn. with $\text{CCl}_3\text{CO}_2\text{H}$. The % compn. of 2 samples was as follows: C 50.76 and 50.03; H 6.57 and 6.66; N (Kjeldahl) 14.0; ash 0.4. P was not present and the Molisch and orcein tests were negative. The av. % distribution of N in 2 samples was as follows: NH_2 9.7, humin 0.4, arginine 10.0, histidine 4.95, lysine 5.1, cystine 0.55, total bases 20.5, total filtrate 67.7, amino N of filtrate 65.2, non-amino N of filtrate 2.5. BzCl and CS_2 completely inactivated the insulin in alk. soln. and HCHO and HNO_2 greatly decreased its activity (the latter more than 95%). "From a consideration of the following points—the action of trypsin, the action of sp. reagents, the chem. tests, the combustion analysis, the distribution of N—the similarity between insulin and a protein is apparent. Whether the purified product used in this study contains 2 or more proteins, having very similar phys. properties, can only be detd. by further research."

A. P. LOTHROP

Action of ether on protoplasm. L. V. HEILBRUNN. *Biol. Bull. Marine Biol. Lab.* **49**, 461-75(1925).—Water enters etherized muscle less rapidly than normal muscle, but this does not necessarily imply a change in the properties of the plasma membrane following etherization. Ether does not lower the permeability of sea urchin eggs to water. Dil ether solns. cause a sharp decrease in the viscosity of sea urchin protoplasm, both in fertilized and in unfertilized eggs. Slightly more concd. ether solns. produce a coagulation which is irreversible.

L. W. RIGGS

Change in the electrical conductivity of visual purple under the influence of illumination. P. LAZAREV. *Compt. rend.* **181**, 476-7(1925).—The retinal purple of the frog was dissolved in solns. of the salts of the biliary acids. After prolonged dialysis the cond. of the soln. of the purple was detd. in the dark and in the light and was found to have the greater cond. in the light. This fact forms the basis of the author's ionic theory of luminous sensations.

L. W. RIGGS

Enzymic hydrolysis of natural and artificial amylophosphates. SAMEC. *Compt. rend.* **181**, 532-3(1925).—A 1% soln. of potato starch, which contains a phosphoric ester, heated to 120° for 30 min. and a soln. of artificial acid amylophosphoric ester were used. Upon these 2 solns. an ext. of the ground seeds of *Glycine hispida* and dry exts. of muscles of porpoise and femurs of the calf were allowed to act at 37°. The operations were protected from bacteria by layers of toluene. At the end of the enzymic action the mixts. were dialyzed in parchment sacs to remove the electrolytes and the remaining mixt. was purified by electrodialysis to a const. cond. The colloidal residue contained the non-dialyzable P which was detd. by burning the sacs. The water in which the dialysis was made contained H_3PO_4 resulting from enzyme action, and at the same time the H_3PO_4 bound to the dextrans or sugars. The quantity of the first was detd. by pptn. by Mg mixt. and after filtration the quantity of the second was detd. in the filtrate. The results assembled in a table show the amts. of P_2O_5 (1) in the colloidal remainder, (2) in the org. dialyzable fraction and (3) in the free dialyzable fraction.

L. W. RIGGS

Influence of the mode of dissolution of amylase on the saccharification of starch. P. PETIT AND RICHARD. *Compt. rend.* **181**, 575-7(1925).—Three methods of dissolving the amylase were tested, *viz.*, boiling water, water agitated by a stream of H_2 , and water agitated by a stream of air. The max. maltose per 100 of starch is attained with a p_{H} of 4.2 and the amylase dissolved in boiling water. Of the other methods of dissolving amylase it was found that H_2 had a less depressing action than air. With solns. of p_{H} 8.0, on the contrary, the soln. of amylase by water charged with H_2 gave the largest yield of maltose, but only about 0.4 that yielded at p_{H} 4.2. With p_{H} 3.2 the results were near those with p_{H} 8.0.

L. W. RIGGS

Acidification of the medium by cellular cytotoxicity. (MMR.) ANNA DRZEWINA AND GEORGES BOHN. *Compt. rend.* **181**, 692-4(1925); cf. *C. A.* **16**, 1279, 2182.—To a tube contg. sea water is added either KCl to make 0.05 N, or an equal vol. of fresh water, and some hundreds or thousands of *Convolvula*. After the lapse of about 15 min. the liquid showed a p_{H} of 4.4 as estd. by methyl red. Thus a few mg. of *Convolvula* can convert the p_{H} of 10 cc. of a liquid from about 7.0 to 4.4.

L. W. RIGGS

Preparation of muscle albumin (myoalbumin) by the acetone method; its principal properties. MAURICE PIETTRE. *Compt. rend.* 181, 737-9(1925).—Muscle plasma, prepd. by grinding and pressure, is satd. with Et_2O and allowed to stand in the cold with occasional shaking for 24 hrs. when it is passed through a cloth filter. This operation with Et_2O and filtering is repeated 4 or 5 times until only a slight ppt. forms and the liquid is almost water white. To 100 cc. of the latter is added 120 to 130 cc. of acetone, a few cc. at a time and with vigorous shaking. A granular white ppt. forms which contains all the proteins of the liquid. This ppt. is filtered off and is dried completely under the air pump. The very hygroscopic cake thus formed is taken up with 30 to 40 cc. of water in which it is mostly sol., and placed in the ice box for 24 hrs. when it is centrifuged, the ppt. is washed with water until the washings are not clouded by heat, to sep. the insol. materials resembling globulins. The aq. liquid and added first washings are satd. with Et_2O for 24 hrs. in the ice box, the slight ppt. which forms is filtered out and a second pptn. is made with 1.3 times its vol. of acetone, followed by taking up with water, agitation with Et_2O and filtration, which gives a solu. of myoalbumin, which is further purified by fractional pptn. with alc. Myoalbumin has properties closely resembling those of serum albumin, lactalbumin and ovalbumin. It is distinguished by its coagulation temp. of 45° to 47° and by its sp. rotatory power of -26.4° to -30° .
L. W. RIGGS

Promoting action of anemic blood upon the formation of red blood-corpuscles. G. FÖRSTER AND F. KISS. *Magyar Orvosi Archivum* 26, 401-6(1925).—The serum of animals made anemic through bleeding, when injected into anemic animals, prevents the reduction of the erythrocytes which otherwise takes place the day after bleeding, and accelerates the process of regeneration. Plasma and hemolyzed red blood corpuscles act in a manner similar to that of anemic serum.
L. W. RIGGS

Mechanism of carbohydrate utilization. A. L. RAYMOND. *Proc. Nat. Acad. Sci.* 11, 622-4(1925).—The mechanism of alc. fermentation as accomplished by enzymes is believed to be as follows: (a) The hexose reacts with inorg. phosphate to form a hexose monophosphate ester; (b) this splits into 2 triose groups one of which contains all of the P; (c) the triose phosphate condenses to a hexose diphosphate and the triose remainder of (b) is transformed into alc. and CO_2 ; (d) the hexose diphosphate is hydrolyzed back to hexose and an inorg. phosphate. The P-free triose of (b), $\text{C}_3\text{H}_6\text{O}_3$, is believed to be a reactive substance which is not identical with any known isomer of this empirical formula, and it is intended to include the hydrated or dehydrated forms such as $\text{C}_3\text{H}_8\text{O}_4$ or $\text{C}_3\text{H}_4\text{O}_2$. The transformation of $\text{C}_3\text{H}_6\text{O}_3$ to alc. and CO_2 is believed to proceed as suggested by Newberg and Kerb (cf. *C. A.* 8, 1805). It is believed that the presence of insulin or an insulin-like material is necessary in order that reaction (a) shall take place. The mechanism of the animal metabolism of carbohydrates is believed to be related to that proposed above for alc. fermentation.
L. W. RIGGS

Inactivation of insulin by glucose with a comment on the genesis of diabetes. J. R. MURLIN. *Science* 62, 332-4(1925).—Insulin treated *in vitro* with glucose loses much of its power to lower the blood sugar of normal fasting rabbits. Fructose has little if any inactivating effect *in vitro* upon insulin. The relations of the liver and pancreas to diabetes are discussed.
L. W. RIGGS

Binding of acid and alkali by proteins. R. A. GORTNER AND W. F. HOFFMAN. *Science* 62, 464-7(1925).—The chem. nature of a protein and the power of a protein to bind acid and alkali in stoichiometrical relationships depend on the chem. groups within the protein mol., and is limited to the range between p_H 2.5 and p_H 10.5. It is suggested that there are 2 types of combinations between proteins and acid or alkali: (1) a chem. type as above indicated and (2) an adsorption type of combination which takes place at p_H values outside of the limits 2.5 to 10.5.
L. W. RIGGS

Ultra-violet radiations and antirachitic substances. J. C. DRUMMOND AND T. A. WEBSTER. *Nature* 115, 837(1925); cf. *C. A.* 2, 3310; 19, 353, 2964. —The fogging of a photographic plate erroneously attributed to the emission by cod-liver oil of invisible ultra-violet light capable of passing through quartz but not through glass may be due to a phosphorescence of the fused silica. Quartz which has been exposed to ultra-violet light may continue to emit rays capable of fogging a photographic plate after 21 days at room temp.
FLORENCE N. SCHOTT

An amphoteric substance in the radula of the whelk (*Buccinum undatum*). C. F. A. PANTIN AND T. HOWARD ROGERS. *Nature* 115, 639-40(1925).—The radula of *Buccinum* seems to consist of 2 zones, a newly formed part (chitin A) and an older part (chitin B). Data are given showing that when these 2 chitins are stained with basic and acidic ions, Ag^+ and $\text{Fe}(\text{CN})_6^-$, at known p_H values, it was found that chitin A combines with both anions and cations irrespective of the p_H . Chitin B appears to be

an amphoteric substance with an isoelec. point at about p_H 2.6. Chitin A seems to undergo a profound change when it is converted into chitin B. F. N. S.

Determination of the calcium-ion concentration by means of indicators; ionic equilibrium in the body. F. HAFFNER AND R. SIMON. *Arch. expl. Path. Pharm.* **109**, 129-42(1925).—The Ca-ion concn., like the H-ion concn., can be detd. colorimetrically by means of acid dyestuffs which enter into combination with Ca. Dianilbraun M11 is the best indicator for use in biol. solns. with a Ca concn. of 0.1-0.001 M. For the increase in Ca ions in inorg. solns. the surviving frog musculature has no buffer effect comparable to that for the p_H . The action of Ca on the size of the frog vessels and on the frog heart is increased by increasing the alky., despite the fact that the concn. of Ca ions is reduced, a result to be interpreted as a sensitization for Ca by OH ions. G. H. S.

Theory of the bioelectric current. W. DEUTSCH. *Arch. ges. Physiol.* (Pfluger's) **209**, 675-84.—Monds' expt. can be readily reproduced, but certain precautions must be observed to obtain abs. values. The time between the prepn. of the phase (protein) and the detn. has an effect, for within a period of 30 hrs. the potential has fallen and after 3 days the change is still greater. In opposition to this the "concn.-effect" increases. The albumin-paraglobulin fraction, as well as hemoglobin, behaves essentially like euglobulin, indicating that for the production of the p. d. lipid substances are not essential. Study of the relation of the protein phase to different electrolyte solns. shows that there is no connection between dyestuff absorption, lipid soly., and the c. m. f. of dyestuffs. Polyvalent cations, such as La, as well as alkaloids such as quinine and cocaine show a moderately great activity. Narcotics like phenylurethan and phenylurea exert no influence on the c. m. f. Reaction changes of the protein phase occur, as in the expts. of Matsuo and Mond, in that a reversal of the direction of the current occurs with change in reaction, i. e., at one time the anion, at another the cation of the electrolyte becomes active. G. H. S.

Preparation and properties of amylase from germinated wheat and rye. N. M. NAYLOR, MABEL SPENCER AND MARGARET HOUSE. *J. Am. Chem. Soc.* **47**, 3037-9 (1925).—The amylases from germinated wheat and rye compare very favorably with amylase from malt described by Osborne and by Sherman on the following points: they are obtained by the same process of dialysis and fractional pptn. with EtOH, they give the typical protein tests and they show optimum activity at a corresponding range of H-ion concn. in the starch substrate. C. J. WEST

The determination of the content of the protein molecule in cyclic complexes. OTTO FÜRTH. *Ergebnisse Physiol.* **24**, 52-66(1925).—A description of the different methods for the detn. of tyrosine, tryptophan and histidine. H. J. DEUEL, Jr.

Barbituric acids and the picric acid reaction. A. W. DOX. *Z. physiol. Chem.* **150**, 118-20(1925).—The red color obtained by treating diketopiperazines with picric

acid and NaOH may be obtained also by treating barbituric acid with the same reagent. However, neither mono- nor dialkylbarbituric acids give this reaction. This is not surprising in the case of the dialkyl derivs., considering their great stability toward oxidizing agents, but is rather significant in the case of monoalkyl derivs. because these contain 2 carbonyls with the same adjacent groupings as the diketopiperazines. It is believed that the color obtained by treating barbituric acid with the picric acid reagent is due to formation of picramic acid, since both the colored product formed in the reaction and picramic acid itself gave a yellow dye when diazotized and coupled with sulfanilic acid. Abderhalden's use of the picric acid reaction for demonstrating diketopiperazines is believed warranted in view of his direct identification of piperazines after reduction and the improbability of the presence of other reacting substances among the hydrolytic products of proteins. The reaction is certainly not obtained with all ring systems contg. the CO group.

Estimation of glucose, especially in urine. L. ROSENTHALER. *Arch. Pharm.* **263**, 518-20 (1925).—The following reagents are required: (1) a soln. of 5 g. $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ in 500 cc. of H_2O ; (2) a soln. of 173 g. Rochelle salt, 45 g. NaOH and 40 g. $\text{K}_4\text{Fe}(\text{CN})_6$ in 500 cc. of H_2O ; (3) a soln. of a cyanide contg. phenolphthalein soln. obtained by treating 0.5 g. phenolphthalein in 30 cc. EtOH with sufficient H_2O in an evap. dish to develop turbidity, addn. of 20 g. NaOH followed by Al powder in small portions sufficient to discharge the color, then diln. to 150 cc. with H_2O . The reagent consists of about 0.1 g. KCN dissolved in 10 g. of the phenolphthalein soln. A mixt. of 10 cc. of soln. (1) and (2) is reduced by 10.45 mg. of glucose. To standardize, heat 10 cc. of soln. (1) accurately measured, 10 cc. of soln. (2) and 10 cc. of H_2O in a 200-cc. Erlenmeyer flask to boiling, then run in from a buret sufficient glucose soln. to develop a green color. A drop of the liquid transferred to a filter paper previously moistened with soln. (3) develops an immediate red spot. Addn. of the glucose soln. is continued drop by drop until the spotting test becomes negative. If 10 cc. had been added up to this point, it would have contd. 10.45 mg. glucose, or had a strength of 0.1015%. In any case a 2nd detn. should be made. In tests involving the accuracy of the method on 4 samples each contg. 0.95% glucose with 1 cc. normal urine, 0.1 g. urea, 0.1 g. NH_4Cl , 0.01 g. uric acid resp., the following values of glucose were found: 1.09, 0.91, 0.96 and 0.98%. W. O. E.

The oxidative enzymes of the leucocytes. HEDWIG MIELKE. *Klin. Wochschr.* **4**, 2201-2 (1925).—The method used was that of Graham excepting that Merck's benzidine tablets, which contain BaO_2 , were used in place of H_2O_2 and benzidine. The results obtained are compared with those obtained by the Graham method. MILTON HANKE.

Estimation of phosphorus compounds in blood. R. V. STANFORD AND A. H. M. WHEATLEY. *Biochem. J.* **19**, 697-705 (1925).—Slight modification of the well-known colorimetric methods. BENJAMIN HARROW.

Estimation of calcium in blood. R. V. STANFORD AND A. H. M. WHEATLEY. *Biochem. J.* **19**, 710-4 (1925).—Ppt. 5 cc. plasma with 25 cc. $\text{CCl}_3\text{CO}_2\text{H}$ (6.5%). To 20 cc. of filtrate in a centrifuge tube, provided with a stirrer, add a drop of methyl red, then concd. NH_4OH in drops until the liquid is just alk., then 0.5 N HCl in drops until the liquid is just acid again. Add 1 cc. 0.5 N HCl, 1 cc. 4% oxalic acid and 1 cc. 26% AcONa . Let stand overnight, centrifuge, and wash the ppt. twice with satd. CaC_2O_4 soln. Dissolve the ppt. in 1 cc. N H_2SO_4 and titrate with 0.01 N permanganate. Distribution of Ca compds. in blood (figures in hundredths of a milligram): plasma, in five cases, from 9.6-11.0; corpuscles, in five cases, from 1.4 to 3.2. B. H.

Estimation of allantoin in presence of uric acid, creatinine and amino acids. EINAR LANGFELDT AND JÖRGEN HOLMSEN. *Biochem. J.* **19**, 715-6 (1925).—The method used was that of Wiechowski (*C. A.* **9**, 2694). The estn. of allantoin by mercury pptn. gives figures for the amt. of allantoin in aq. soln. which are not more than 10% below the real amt. In the presence of amino acids in small quantities, and of creatinine and uric acid in quantities such as are contained in normal urine, the figures for allantoin are higher and closer to the real amt. When the amino acids are present to the extent of 0.2% or over, the figures are too high. BENJAMIN HARROW.

The isolation of natural crystallized lecithins. H. H. ESCHER. *Helvetica chim. acta* **8**, 686-91 (1925).—A pure phosphatide product is the prerequisite for the prepn. of cryst. lecithins. Five to 10 kg. cautiously dehydrated egg yolk or ox brain was extd. with boiling alc. and CHCl_3 until the snow-white protein powder yielded no more to the solvent. The concd. soln. was pptd. with acetone. The addition product of phosphatides and acetone is always amorphous, often smeary. Cryst. ppts. indicate contamination by proteins. Speed is essential; the prepn. including mincing must be completed in 2-6 hrs. The nearly colorless product, which can be powdered when

dry, is relatively unstable in air. Properly stored it remains unchanged for years. Lecithin was isolated from this product by fractional crystn. from abs. alc. After the removal of the cephaline and sphingomyelin fractions at room temp. and below 0°, 75% of the phosphatides consisting of lecithins crystallized at -35°. It melts below 0°. The fraction least sol. in ether, m 244-5° is snow-white, hygroscopic and has the I value 50, corresponding to 1.5 double bonds. From the mother liquid two other lecithins with 2.5 and 3.5 double bonds were isolated.

Metabolism of acid-fast bacteria. V. The quantitative metabolism expenditure of the timothy bacillus and of the trumpet bacillus. H. WOLFF. *Biochem. Z.* 158, 319-33 (1925).—The quant. needs of the timothy bacillus and the trumpet bacillus for Mg, K, Na, S, P, N and C were detd. by recording the bacterial growth in media to which varying amts. of the element under investigation were added. From such data, media favorable for the max. growth of the bacillus can be constructed.

F. A. CAJORI
Use of dyes in agar media. MAX LEVINE. *J. Am. Water Works Assoc.* 14, 267-72 (1925).—Variation in the actual dye content of available American and foreign dyes used in eosin-methylene-blue agar has resulted in a need for some type of control and certification.

D. K. FRENCH
Bacillus typhosus morphologically compared with certain bacilli present in natural waters. LUCIUS NICHOLS AND EDWIN BURGESS. *Ceylon J. Sci.* (Sect. D, Med. Sci.) 1, pt. 2, 47-56 (1925).—*B. typhosus* could be distinguished morphologically from *B. coli* and any of 40 bacilli isolated from water. Cultures for comparison were grown on nutrient agar contg. 0.5% added NaCl, on similar agar contg. 1% NaCl and on similar agar contg. no added NaCl. The 40 bacilli isolated from water were capable of producing acid and gas from lactose broth in 33 cases, and capable of producing acid but not gas in 6 cases. A plea for more careful morphological study of the organisms is made.

JACK J. HINMAN, JR.
Observations on the cultural and biochemical characters of *Monilia castellanii* (*Cryptococcus castellanii*) and *Monilia macroglossiae* (*Cryptococcus macroglossiae*). SERGIO RE. *J. Trop. Med.* 28, 317-9 (1925).—The organisms are cultured on various media and the results obtained confirm Castellani's description of the two fungi.

FRANCES KRASNOW
Virulence of cholera vibrios in relation to the age of the cultures. M. MELNIK. *Compt. rend. soc. biol.* 92, 941-3 (1925).—Agar cultures have a max. virulence at the age of 16 hrs; bouillon cultures, 4 days; the curve of virulence of the culture on agar rises and declines rapidly, while that of bouillon cultures rises slowly and remains for a long time at a const. level, then commences to decline slowly.

S. MORGULIS
Effect of the products of autolysis of different organs on methanol extracts of tubercle bacilli and of the timothy bacillus. L. ISAFU. *Compt. rend. soc. biol.* 93, 249-50 (1925).—Most of the internal organs of mesodermic or endodermic origin neutralize or inhibit the action of MeOH exts. of tubercle bacilli and the timothy bacillus, while brain tissue of ectodermic origin is entirely without influence.

S. MORGULIS
The determination of the energy by which *Bacterium coli* develops at the expense of glucose. OTTO FURTH. *Ergebn. in Glucose media breaks down this sugar first to pyruvic acid,*

Methods for the detn. of the synthesis of the living cells. The source of energy is lactic acids and the ans of which the organism breaks the pyruvic acid down to Bacterium coli grow in which acid is grow.

G. F. REDDISH

The total luminous efficiency of luminous bacteria. E. N. HARVEY. *J. Gen. Physiol.* **8**, 89–108(1925).—The light emitted by a single individual of *Bacterium phosphorescens* was calcd., also its O_2 consumption in sea water. Intensity of luminescence does not diminish till the O_2 concn. falls below 2%, after which it decreases rapidly. Above 2% O_2 , the bacteria use equal amts. of O_2 in equal times; below this value, the rate of O_2 absorption is probably proportional to the O_2 concn. The max. light from a single bacterium was 24×10^{-14} lumens (19×10^{-14} candles); the max. value in lumen secs. per mg. O_2 absorbed was 14, av. 9.25. The total luminous efficiency was 0.00156. Since some of the O_2 is used in respiratory oxidation the luminescence efficiency must be higher. KCN may reduce the O_2 consumption to $1/20$ the original value, but reduces luminescence to only $1/4$ its original value. By separating respiratory from luminescence oxidation in this manner, the luminous efficiency is 5 lumens per watt or 0.0078 which compares favorably with 16 lumens per watt for a tungsten vacuum lamp or 3.9 lumens per watt for a tungsten nitrogen lamp. The specific luminous emission of this bacterium is 3.14×10^{-6} lumens per sq. cm. One bacterium absorbs 215,000 molecules O_2 per sec. and emits 1,280 quanta of light at $\lambda_{max} = 510\mu$. By assuming that 1 mol. O_2 uniting with luminous material results in the emission of 1 quantum of light energy, only $1/168$ of the absorbed O_2 is used in luminescence and the luminous efficiency becomes 168 lumens per watt or 26 2/3%. C H R

Germicidal action of certain vegetable essences. A. MOREL AND A. ROCHAIX. *Bull. sci. pharmacol.* **32**, 257–70; *Parfumerie moderne* **18**, 261–9(1925).—The essences were tested in the gaseous and in the liquid form on meningococci, *B. typhosus*, staphylococci, *B. diphtheriae* and anthrax bacilli. When applied in a state of vapor the germicidal activity decreased in the following order: lemon, thyme, orange, bergamot, juniper berry, clove, citronella, lavender, gomenol, mint, rosemary, santal, eucalyptus, badian. When applied in the liquid state the order of decreasing activity was thyme, lemon, juniper berry, mint, gomenol, orange, citronella, cloves, lavender, rosemary, bergamot, eucalyptus, santal, anise, badian. A given bacterium differs more or less in its resistance to different essences. L. W. RIGGS

Asepsis. H. HALILAY. *Indian Med. Gazette* **60**, 455–9(1925).—Most high-pressure steam sterilizers are too small and are likely to be overloaded. The steam pressures at which the sterilizers are worked are usually too low to insure complete sterilization. A pressure of 30 lbs. is necessary, although this is a higher pressure than many sterilizers on the market are designed to stand. Flowers of S placed in the middle of the drum with the goods will show whether a temp. of 114.5° has been reached. It is difficult to heat the interior of a drum tightly packed with surgical dressings. L. W. RIGGS

Therapeutic preparation of lactic acid bacilli. J. REICHEL AND C. ROOS. U. S. 1,540,951, June 9, 1925. A culture medium prepd. from casein by digesting it with trypsin and rendering it alk. with Na_2CO_3 is used for the propagation of *B. acidophilus* or *B. bulgaricus*, the bacilli are sepd. by settling or centrifuging, mixed with yeast and the mixt. is compressed.

D—BOTANY

B. M. DUGGAR

The action of photocatalyzers on the early sprouting of resting buds and on the germ. A. NIETHAMMER. *Biochem. Z.* **158**, 278–305(1925).—The bursting of winter buds and the germination of seeds were found to be accelerated by continuous illumination by artificial light of high intensity (300 Hefner candle). The effect of light was increased when such photocatalyzers as eosin, erythrosin, methylene blue, $FeSO_4$, $Fe(SO_4)_3$ and $U(SO_4)_2$ were injected directly into the buds, or in the case of the seeds placed in the bath in which the seeds were germinated. F. A. CAJORI

The action of sodium carbonate on germs and plant growth. D. FEHÉR AND ST. VÁGI. *Biochem. Z.* **158**, 357–65(1925).—The toxic action of Na_2CO_3 on plant growth is believed to be due to NaOH formation by hydrolysis. If the OH ion is depressed, as by the presence of humus, Na_2CO_3 is less toxic. A concn. of 0.4 to 0.5% Na_2CO_3 completely hindered germination and growth of wheat 1.5% Na_2CO_3 in sandy soils checked growth. Trees are less resistant to Na_2CO_3 than other plants. F. A. CAJORI

The effect of wounds upon the rotation of the protoplasm in the internodes of Nitella. SUSAN P. NICHOLS. *Bull. Torrey Bot. Club* **52**, 351–63(1925).—Initial puncture of the cell wall by a needle usually results in immediate cessation of protoplasmic streaming throughout the cell. The opening is plugged in a few min. and rotation resumed, except in a zone extending in the direction of movement

from the wound. On repeated puncture the streaming shows less general and prolonged interruption. A toxic substance may be formed by the injured protoplasm and carried out into the cell by currents flowing over the injury, causing stoppage of movement. On repeated wounding an antitoxic substance may be developed, resulting in lessened interference with streaming. Or puncturing may result in increased viscosity or the setting of the protoplasm into a gel. JOSEPH S. CALDWELL

The chemical constituents of the fruit walls of Myxomycetes. ALEXANDER KIESSEL, *Z. physiol. Chem.* **150**, 102-17 (1925).—The air-dried fruiting bodies of *Lyogala epidendron* were crushed and emptied of their spore contents by shaking, then repeatedly washed with H_2O and finally dried at $108-10^{\circ}$. Analysis showed 3.63% N, 3.98% Et_2O ext., 2.84% ash. Hydrolysis by acid gave reducing sugar equiv. to 50.5% of the material. This was identified as glucose by the prepn. of osazone and no other sugar could be demonstrated. Treatment of the wall substance with 2% H_2SO_4 left 58.38% undissolved, and prolonged treatment with 66-80% acid left 27.63% of residue. Alkali fusion at $160-80^{\circ}$ dissolved 98.1-99.3% of the material with evolution of NH_3 . The N free poly-saccharides may be sepd. from the N-contg. substances by treatment with 8% $NaOH$ at water bath temp., and the insol. residue thus obtained accounts for 90.5% of the total carbohydrate. Hence if glucosamine-contg. carbohydrates occur, other nitrogenous substances, e. g., proteins, must also be present. For the polysaccharide insol. in hot 8% $NaOH$ the name *myxoglucan* is proposed. The amt. of NH_3 liberated from the material by boiling with 8% $NaOH$ and that obtained by alkali fusion were identical and represented 18.5% of the total N. The N rendered sol. by acid hydrolysis represented 66.7% of the total. Neither glucosamine nor protein was actually demonstrated, but it is believed that the greater part of the N is present in protein like substances, especially since treatment with pepsin-HCl dissolved a considerably greater portion of the N than did the same concn. of HCl alone. A. W. D.

Continuous respiration studies of dormant seeds of Xanthium. JUNJI OTA, *Bot. Gaz.* **80**, 288-99 (1925).—There is an increase in the respiration rate of dry seeds during the first day of subjection to favorable germinative conditions in the respirometer, then the respiration falls rapidly to a low level, after which there is a slow decrease in rate as long as the expt. is continued. If the seeds are soaked in cold water previous to placing them in the germinator, the respiration rate reaches its max. earlier than unsoaked seeds, otherwise the curve is the same as that for unsoaked seeds. Respiratory activity runs parallel with catalase activity. BENJAMIN HARROW

The variation in the moisture and nitrogen content of the potato during growth and storage. T. W. FAGAN, *Welsh J. Agr.* **1**, 110-5 (1925).—A gradual decrease in moisture and a corresponding increase in dry matter occurred in potatoes during growth. The percentages of total N and protein N both showed a steady increase. The ratio of protein N to total N also increased until at the time of harvesting it was 55 to 58% of the total. In expts. during two seasons the compn. of the potatoes at the time of harvesting was H_2O 77.33-78.12, total N 0.316-0.297, and protein N 0.181-0.161, resp. Similar variations during growth also occurred in the leafy portion of the plants, the compn. at the time of harvesting being H_2O 22.19-30.32, total N 1.149-1.014, and protein N 0.970-0.812, resp. The percentages of total N and dry matter increased slightly during storage but the ratio of protein to total N remained fairly constant. K. D. JACOB

The influence of environment on the protein content of wheat. F. T. SHUTT, *Can. Chem. Metallurgy* **9**, 195-7 (1925).—The protein content of wheat was increased by 6.15% and reduced by 6.18% through environmental factors. H. R. KRAYBILL

The chemistry of Japanese plants. III. Chemical development in the growth of bamboo shoots. SHIGERU KOMATSU AND CHOJI TANAKA, *Mem. Coll. Sci. Kyoto Univ.* **9A**, 1-14 (1925); cf. *C. A.* **18**, 849; **19**, 2840. Bamboo shoots from 5 different sections of the jungle were cut into 5 pieces each and analyzed. The upper portions of the shoots contain the least carbohydrates and the largest amt. of simple nitrogenous substances and fatty acids. The pentosan content was const. throughout the shoot. The total ash content decreases with age. H. R. KRAYBILL

Attempt to prove Wieland's theory of respiration. K. TANAKA, *Biochem. Z.* **157**, 425-33 (1925).—In order to prevent the decompn. of H_2O_2 formed during the oxidation of CO, HCN dissolved in H_2SO_4 is used. The yield of H_2O_2 increases from 6% of the theoretical yield without the HCN to 61% with HCN. However, no H_2O_2 could be demonstrated to be formed in the oxidation of EtOH. HCN does not prevent respiration by *Chlorella*, but no H_2O_2 is formed in the dark although H_2O_2 is formed in the light, when O_2 and not CO_2 is given off. Therefore, the H_2O_2 is formed because of a photo-oxi-

dation of the chlorophyll. The Traube-Wieland reaction is, therefore, either not involved in respiration, or does not go on to an appreciable extent. W. D. L.

Presence in the emulsin of almonds of two new enzymes, primeverosidase and primeverase. MARC BRIDEL. *Compt. rend.* **181**, 523-4 (1925), cf. *C. A.* **19**, 2514.—The emulsin of almonds, when used in sufficient amts. and for sufficient time (30 days), hydrolyzes an aq. soln. of monotropitoside. The hydrolysis is not arrested by primeverose, the latter being hydrolyzed to glucose and xylose. Therefore, the emulsin of almonds contains 2 enzymes which have not been noted hitherto, *viz.*, *primeverosidase* and *primeverase*. L. W. RIGGS

Sugars furnished by gein. H. HERISSEY AND J. CHEYMOL. *Compt. rend.* **181**, 565-6 (1925); cf. *C. A.* **19**, 1442.—Gein extd. from underground parts of *Geum urbanum* L. upon hydrolysis with boiling dil. H_2SO_4 yields *d*-glucose and *l*-arabinose. Hydrolysis of gein by gease gives *vicianose*, a sugar hydrolyzable by boiling dil. acids to *d*-glucose and *l*-arabinose. After vicianin from seeds of *Vicia angustifolia*, gein becomes a second actual source of vicianose. L. W. RIGGS

Energy yield in the development of various vegetable organisms as a function of the oxygen content of the surrounding air. EMILE P. TERROINE, R. BONNET AND A. HÉE. *Compt. rend.* **181**, 685-7 (1925).—Expts. to det. the energy yield during 3 days growth of *Sterigmatocystis nigra* in atm. contg. from 21 to 100% of O_2 , also to det. the energy yield of germinating lentils and black soy beans in air and in O_2 proved that an increase in the percentage of O_2 in the atm. surrounding the organism even up to 100% does not affect the yield of energy. L. W. RIGGS

Influence of the conditions of the medium on the germination of seeds in the absence of calcium. R. CÉRIGHELLI. *Compt. rend.* **181**, 728-30 (1925).—Maquenne and Demoussy (cf. *C. A.* **11**, 2817, 2922) proved that Ca is indispensable to the normal germination of seeds. C. found this condition to hold whether the medium was sterilized or not, whether the cotyledons were immersed or not, and whether the operation was carried out in pure water or in the vapor of water. L. W. RIGGS

Rapid method for demonstrating the effect of plants on a culture solution. P. L. HIBBARD. *Science* **62**, 515-6 (1925).—A method is given for sprouting wheat seeds and cultivation of the plants to a height of 10-15 cm. On successive days the bundle of plants is supplied with dil. solns. of single salts in a vol. sufficient to keep the roots immersed. At the end of the period of absorption the remaining soln. is made up to its original vol. with distd. water, and the liquid tested for the ions remaining. In this way culture solns. contg. the following named plant foods, resp., were tested: KNO_3 , KCl , $Ca(NO_3)_2$, KH_2PO_4 , $KHCO_3$, $NaNO_3$, $Mg(NO_3)_2$, $(NH_4)_2SO_4$, and $MgSO_4$ were tested. The pH was detd. in each solution after absorption by the plants by means of phenolsulfonephthalein indicators. In some cases the same culture soln. was tested after different periods of absorption. The usual pptg. reagents were used for Ca, Mg, sulfate and phosphate. Sodium cobaltinitrite was used for K and diphenylamine for nitrate. L. W. RIGGS

Acidity produced in salt solutions by Sphagnum. MACGREGOR SKENE AND GLADYS L. STUART. *Nature* **115**, 605-6 (1925).—A pH detn. of salt solns. contg. *Sphagnum* gives the same values as does that of solns. of $NaCl$ and HCl , and corresponding salt acid mixts. of the other salts employed, *viz.* pH 4.6, 4.6, 5.5, 5.9, 9.5, for $NaCl$, Na_2SO_4 , $NaOAc$, Na citrate, Na borate. These results seem to prove that the acidity produced in these salt solns. after shaking with *Sphagnum* is due to the acid of the salt employed, and not to org. humic acids as suggested by Odén. FLORENCE N. SCHOTT

The root bacilli of "Diplotaxis erucoides," D. C. R. PEROTTI. *Atti accad. Lincei* [6], **2**, 46-52 (1925).—In extending the work on this organism P. (*Atti acad. Lincei*, **28**, I, 331; **29**, II, 361) studied the influence of the bacteria on the N nutrition of *Diplotaxis erucoides*, D. C. *Diplotaxis erucoides* is damaged by the absorption of ammo. compds. (asparagine) and in the presence of NH_3 or nitric N definitely prefers the latter. This plant showed itself adapted to substrates poor in N and may be said to be oligotrophic. N balance studies showed a gain of N in the plant when no N compds. were supplied. The role of bacteria in the fixation of molecular N_2 in non-leguminous plants is still incompletely known. E. J. WITZEMANN

PHILIP B. HAWK

The specific dynamic action of foodstuffs and their relation to the basal metabolism in diabetes. H. C. GEELMUYDEN. *Ergebnisse Physiol.* **24**, 1-42(1925).—The theories on the causes of specific dynamic action are much at variance with the generally accepted views of the American school. The specific dynamic action of carbohydrates is caused by the formation of glycogen, an exothermic reaction, while that of fat is bound up with the change of its decompn. products (CH_3COOH and $\text{CH}_3\text{COCH}_2\text{COOH}$) to glucose. The sp. dynamic action of the amino acids is partly traced to the deamination and the formation of urea and partly to the change of the non-nitrogenous residues into glucose. Their relation to the basal metabolism in diabetics is discussed.

H. J. DEUEL, JR.

The simultaneous experimental production of severe xerophthalmia and rickets in young rats. WILHELM STEPP. *Ergebnisse Physiol.* **24**, 67-70(1925).—On raising the CaCO_3 content of a xerophthalmia-producing diet (oat flakes 40.0%, casein 5.0%, NaCl 1.0%, CaCO_3 1.5%, dextrin 52.5%) to 3.0%, typical rickets was produced simultaneously with xerophthalmia in young rats fed 4-5 weeks on this ration.

H. J. DEUEL, JR.

Antineuritic yeast concentrates. I. H. W. KINNERSLEY AND R. A. PETERS. *Biochem. J.* **19**, 820-6(1925); cf. *C. A.* **19**, 95. K. and P. used pigeons for their test material. They call "torulin" the principle in yeast which cures symptoms of head retraction in pigeons induced by feeding upon polished rice. The activity of the products was measured by using the equation torulin activity = no. of days' protection after cure/wt. in mg. of the dry prepn. $\times 100$. Up to the stage involving the use of acid alc. to ext. torulin from the charcoal, the technic used was the same as that previously described (see *loc. cit.*). Treatment with BaS was omitted; instead, charcoal absorption was applied direct to the acid fluid after removal of the Hg ppt. The subsequent treatment includes many steps, involving the use of 60% alc., Pb acetate, 90% MeOH, dialyzed Fe, alc., ether and fractionations in mixts. of alc. and ether. The authors obtained a yeast concentrate of 1190 T. A. (torulin activity) which cured and protected in doses of 0.084 mg. per day, but did not cause increase in the weight of pigeons after cure of the polyneuritic symptoms. This supports the view that what is commonly called vitamin B probably consists of 2 factors. B. H.

Survey of acid milk in infant feeding. VIRGINIA T. WEEKS. *Arch. Pediatrics* **42**, 722-34(1925).—The types of acid milk used contain lactic acid, vinegar (AcOH), citric acid (lemon juice), or HCl . The acid decreases the buffer action of the milk, and increases gastric activity and the peptic digestion of the milk proteins. Lactic acid milk is preferred; it can be tolerated by infants for a long period of time; HCl milk is least popular. Vinegar milk and lemon juice milk yield good results; the latter also has antiscorbutic properties. A bibliography is appended. J. S. H.

Dried milks for infant feeding. ALICE D. WEBER. *Arch. Pediatrics* **42**, 735-42(1925).—A concise summary, with bibliography, of the prepn. of dried milk on the com. scale, and of its use in pediatrics. JOSEPH S. HEPBURN

Protein milks in infant feeding. V. A. BLENKLE. *Arch. Pediatrics* **42**, 743-60(1925).—A concise description, with bibliography, of the various com. protein milks and their use in pediatrics. JOSEPH S. HEPBURN

Thick cereal formulas and butter flour mixtures in infant feeding. R. A. ECKHARDT. *Arch. Pediatrics* **42**, 761-6(1925).—The prepn., chem. compn., and use of these high calorie diets are described. A bibliography is appended. J. S. H.

Comparison of deficiency of vitamin A and of total underfeeding on the development of the organism. H. SIMONNET. *Bull. soc. hyg. aliment.* **13**, 419-43(1925).—Comparative expts. with rats show that during the first period of deficient diet the animals having the deficient diet behave like those fed normally as regards the amt. of food ingested. The phase preceding the second period is characterized by an appreciable decrease in the amt. of food ingested. During most of the equil. period the amt. of food taken spontaneously by the animals with deficient diet is remarkably const. The third period is not one of true inanition, as the animals still take an appreciable quantity of nourishment. The amt. of food taken per 100 g. body wt. decreases regularly with both normally and deficiently fed animals, though with slight differences in both cases. When the deficiency is removed, the animals take more food for a few days, and then reduce the amt. to its original value, showing that an amt. which was insufficient with a deficiency of vitamin becomes sufficient when vitamins are supplied. Rats given *ad lib.* of a deficient diet do not utilize the food as efficiently (whether considered per

animal or per 100 g. body wt.) as those underfed by giving them a complete diet to the same amt. as freely taken by those with deficient diet. With the deficient diet, the thymus gradually disappears, the testicles become atrophied and the reserve fat disappears; while with the complete diet the thymus persists, the wt. of the testicles remains const. and the reserve fat persists. With very young animals, under feeding has much greater effects than in older animals.

A. PAPINEAU-COUTURE

Avitaminosis C (with or without tuberculosis) and the cholesterol of the blood and of the suprarenals. G. MOURIQUAND AND LEULIER. *Compt. rend.* **181**, 434-5 (1925).—Acute or chronic avitaminosis C is accompanied by profound disturbances in the metabolism of the cholesterol of the suprarenals, even if these disturbances are without appreciable relation to the cholesterolemia. The disturbance is aggravated by the association of tuberculosis with the alimentary deficiency.

L. W. RIGGS

Vitamin A in beef, pork and lamb. RALPH HOAGLAND AND G. G. SNIDER. *J. Agr. Research* **31**, 201-21 (1925).—Feeding tests with the albino rat using 10 samples of beef from a like number of cattle showed that none of the samples supplied sufficient vitamin A to induce normal growth when used to the extent of 15-30% in the rations, but that nearly sufficient vitamin A for normal growth was furnished when the samples were used in proportions of 50-95%. Results obtained with dried fresh pork as a source of vitamin A were less satisfactory than those obtained with beef. In tests made with lamb, 3 of the 6 samples examd. were rather poor in vitamin A, one contained a fair proportion while the remaining 2 were richer in vitamin A than any of the other samples of meat used in the tests.

W. H. ROSS

Effect of nourishment on cell function. III. E. ABDERHALDEN AND ERNST WERTHEIMER. *Arch. ges. Physiol.* (Pflüger's) **209**, 611-2 (1925); cf. *C. A.* **19**, 1589.—When proper precautions are taken in making the detns., particularly as regards the p_{H_2} , the total hippuric acid values are essentially the same in animals fed upon oats as in those fed upon green foods. Type of food does modify, as previous expts. have shown, the ability to synthesize mercaptal acids.

The determination of the primary ether extract of blood. H. I. BING AND H. HECKSCHER. *Biochem. Z.* **158**, 395-402 (1925); cf. *C. A.* **19**, 2218, 2232.—The primary ether ext. of blood contained neutral fat and cholesterol. The normal variation of this ext. in man was found to be from 0.06% to 0.12%, as detd. nephelometrically.

F. A. CAJORI

Muscular exercise, lactic acid and the supply and utilization of oxygen. A. V. HILL AND C. N. H. LONG. *Ergebnisse Physiol.* **24**, 43-51 (1925); cf. *C. A.* **19**, 673.—An abstract of earlier papers which represents an attempt to apply to man the principles discovered by the investigation of isolated muscle. The role of lactic acid in muscle contraction is discussed as well as its presence in man, likewise, the relation between muscular exercise and oxygen intake and oxygen requirement, the oxygen debt, and the recovery process after exercise is dealt with.

H. J. DEVEL, JR.

The extrahepatic formation of bilirubin. F. C. MANN. *Ergebnisse Physiol.* **24**, 379-98 (1925).—A yellow pigment accumulates progressively in the urine, plasma and fatty tissues following hepatectomy in the dog. It is usually noted in the first sample of urine secreted after the removal of the liver. In from 3 to 6 hrs. after the operation, the plasma becomes yellow-tinged. In animals which live 16 hrs. or more after hepatectomy, the sclerae also become tinged, at autopsy all the fatty tissue of the body is found to be a dirty yellow. The formation of this yellow pigment which gives a positive reaction for bilirubin is not dependent on any of the intraabdominal organs or the liver. Its rate of development under certain conditions is accelerated by the intravenous injection of laked blood. It seems highly probable that normally a high percentage of the bile pigment excreted by the liver is extrahepatic in origin. The site of the formation of bile pigment is not detd. but probably occurs in the bone marrow or lymph nodes or possibly also in the endothelial cells throughout the body.

H. J. D., JR.

A new simple colorimetric micro-method for the determination of blood sugar, and contributions to the physiology of blood sugar. I. B. GLASSMANN. *Z. physiol. Chem.* **150**, 16-43 (1925).—The method is based on the fact that glucose forms a yellow

condensation product with resorcinol when the mixt. is heated in the presence of HCl . The product is probably an *anhydrodiglucoresorcinol*. Detn. is made by comparing the color with that obtained by the same treatment of a standard glucose soln. In the micro-method the blood sample (0.1 cc.) is absorbed on a strip of blotting paper and the glucose extd. with EtOH . After evapn. of the solvent the residue is treated with 2 cc. of 1% resorcinol and 4 cc. of 25% HCl and heated in a boiling water bath 1 hr. The standard glucose soln. (0.5%) and a paper blank are simultaneously treated in the same way. The color comparisons must be made at about 60° to prevent opalescence; hence the usual type of colorimeter is not suitable. The 3 tubes are, therefore, immersed in hot H_2O in a special contrivance and color comparisons made by diln. with H_2O until the colors match. The method is sensitive to 0.01 mg. glucose, and has the enormous advantage of excluding all other reducing substances present in the blood. It is applicable also to the detn. of sugar in other body fluids. Examn. of the blood of healthy fasting persons by this method showed, in contradiction to the prevailing dogma, that 45% of the blood samples were sugar-free or practically so, although precautions for the prevention of glycolysis were rigidly observed. The hypoglycemic syndrome, therefore, is not based on the fall of blood sugar below a definite value, but is to be ascribed to the action of a poison which, under the influence of insulin, accumulates in the blood and is neutralized by glucose or its cleavage products. The av. of 9 detns. of sugar-positive blood samples during inanition was 0.077% glucose, and of 11 detns. after meals 0.118%. Sugar detns. on the blood and urine of diabetes showed that no parallelism exists between hyperglucemia and glucosuria, but that a higher glucosuria seems to correspond to a higher hyperglucemia. Comparative detns. by this method and by the micro-method of Bang on diabetic and normal persons showed that reducing substances are included in the Bang detn. on diabetic blood and these may exceed the actual sugar content; in the blood of healthy persons, on the other hand, the differences between the 2 methods lie within the limits of error. The av. of 3 detns. on chicken blood was 0.112%, whereas the literature gives 0.2%. EtOH exts. no glucose from the erythrocytes of sheep blood, but if the erythrocytes are first hemolyzed the sugar values of the serum and of the corresponding erythrocyte soln. are practically equal. The blood sugar is not identical with ordinary chem. pure glucose but represents a more reactive form.

A. W. DOX

Metabolism of the nursing infant. J. ELLINGHAUS, ERICH MÜLLER and H. STEUDEL. *Z. physiol. Chem.* **150**, 133-48 (1925).—Metabolism expts. with infants during alternate dietary periods of human milk and of cow milk mixt. showed that the urinary N , NH_3 , urea, uric acid, creatinine and amino acids do not correspond to those of adults on the basis of body wt. If, however, the comparison is made on the basis of body compn., i. e., the smaller proportion of muscular and larger proportion of glandular tissue in the infant, and therefore relatively higher glandular and lower muscular activity, then the metabolism of both infant and adult is found to be comparable. Where slight variations are noted they may be attributed to the factor of growth impulse. Otherwise there is no basis for the assumption that the metabolism of infants is in any way essentially different from that of adults.

Contributions to the study of brain metabolism. II. Carbohydrate metabolism. E. G. HOLMES and B. E. HOLMES. *Biochem. J.* **19**, 836-9 (1925); cf. *C. A.* **19**, 3108. — A comparison of blood-sugar values and resting lactic acid content of the brains of rabbits shows that the fall of the latter resulting from the injection of insulin does not occur until the blood sugar has reached a fairly low level. At the convulsive or flaccid (pre-convulsive) stage the brain lactic acid content is very small. It appears probable that the fall in the resting lactic acid content of the brain after insulin injection is not due to a direct effect of insulin in promoting increased oxidation of lactic acid, but is rather caused by a fall in the blood-sugar level, and the resulting shortage of glucose in the brain.

BENJAMIN HARROW

Chemical and physical studies on mineral, particularly iron, metabolism. OSKAR BAUDISCH and L. A. WELO. *Naturwissenschaften* **13**, 749-55 (1925). — Clear mineral water from Franzensbad, Czechoslovakia, (0.0178 gr Fe^{++} kg.) direct from the source was sealed in evacuated flasks. On exposure to light the contents became opalescent and turbid, whereas in the dark the water kept its original properties. The ppt. formation runs parallel with the disappearance of the catalytic power of the mineral water; light accelerates the aging. The iron at first is present in the "active" form, repeatedly described by B. in previous papers. The biol. properties of mineral waters are discussed from the point of view of Werner's coordination theory and the action of light.

B. J. C. VAN DER HOEVEN

Physico-chemical influences on nerve stimulation. II. Influence of ion con-

centration and osmotic pressure. USHIO TANAKA. *Z. Biol.* **83**, 399-414(1925).—None of the solns. used maintained the conduction speed at such a high level as isotonic Ringer's soln. More often there was a decrease in the conduction speed to a greater or less extent. Hypertonic solns. do not increase the conduction rate of the stimulus. An increase was experienced with solns. having normal osmotic pressure and $\frac{1}{2}$ the ionic concn.

FRANCES KRASNOW

The sedimentation rate of erythrocytes. VIII. The effect of diluted plasma and serum on the sedimentation rate of erythrocytes. F. v. KRÜGER. *Z. Biol.* **83**, 435-44 (1925); cf. *C. A.* **19**, 2230.—With increase in diln. (water) of plasma and serum, the sedimentation rate decreases. The effect in serum is more marked. There is a greater diminution in the sedimentation rate in 2% NaCl soln. than in distd. water despite equal viscosity. The decrease is greater when diln. is made with hypertonic NaCl soln. Diln. with cane sugar has like effects.

FRANCES KRASNOW

Skin temperatures in normal children. F. B. TALBOTT, ALICE J. DALRYMPLE AND MARY F. HENDRY. *Am. J. Diseases Children* **30**, 483-90(1925).—The temp. of the skin under clothing varies, that of the trunk being higher than the extremities and exposed parts of the body. Exposure to room temp. resulted in an immediate fall in skin temp. without any change in rectal temp. The skin, therefore, has some power of regulating the rate in which the heat is transported to it, and is able to prevent heat loss as it is able to accelerate heat loss by perspiration. **Skin temperature and basal metabolism during fasting.** *Ibid* 491-5. During fasting the rate of heat production in the body diminishes. The longer the fast the greater the fall in the skin temp. The pulse rate was lowered and sometimes also the blood pressure. I. N. KUGELMASS.

Binding of calcium by animal tissues. XI. TH. BREHME AND P. GYÖRGY. *Biochem. Z.* **157**, 243-52(1925); cf. *C. A.* **19**, 2371.—To show whether a protein in cartilage with an isoelec. point more to the acid side than that of serum albumin is responsible for Ca deposition, the effect of neutralized yeast nucleic acid upon Ca deposition is detd. When Na nucleate, serum albumin, globulin, fibrin and hemoglobin are dialyzed against Ca solns., they take up increasing amts. of Ca in the order named. This explains the unequal distribution of Ca between a cell and its nucleus. The distribution of Ca also depends upon the concn. of diffusible Ca present, and upon the Donnan equil. **XII.** OTTILIE BUNDE. *Ibid* 253-62. When solns. of $\text{Ca}_3(\text{PO}_4)_2$ are dialyzed against gelatin, the ratio Ca/PO_4 on the side of the gelatin increases markedly for 6 hrs. and then decreases. When agar is used in place of the gelatin the variation is negligible. Therefore, the theory of Freudenberg and György that protein plays an active role in calcification is substantiated. W. D. L.

Chemistry of the blood during parenteral excitation of the activity of digestive glands, especially of the stomach. K. ONOHARA. *Biochem. Z.* **157**, 271-6(1925); cf. *C. A.* **19**, 1883.—From the variations in H_2O and Cl content of blood after injection of pilocarpine, secretin, acetylcholine and atropine, it is found that H_2O generally decreases and Cl varies as the H_2O varies. These changes are similar to the changes caused by ingestion of a protein or carbohydrate meal. Replacement of the H_2O lost occurs by a transference of H_2O from tissues to blood. It is not known whether this compensatory transference of H_2O and Cl from the tissues is due to an enteral stimulation due to circulatory changes, or to a reflex action of the mucous membrane of the stomach upon the tissues. W. D. L.

The speed of settling of erythrocytes and the Hofmeister series. D. v. KLOBUSITZKY. *Biochem. Z.* **157**, 277-82(1925).—Blood from the dog was mixed with CaCl_2 , NaCl, KCl, NH_4Cl , Na_2SO_4 , NaNO_3 , NaBr, NaI and NaSCN, and the rate of settling of the corpuscles compared. The effect of the salts showed that they formed a Hofmeister series. Added sugar quickened the rate of settling. W. D. L.

Blood clotting and the Hofmeister series of ions. J. CSAPÓ AND D. v. KLOBUSITZKY. *Biochem. Z.* **157**, 354-8(1925).—The salts of K decrease the time of blood clotting in the order $\text{SO}_4 < \text{Cl} < \text{NO}_3 < \text{Br} < \text{I} < \text{SCN}$; salts of Na in the order $\text{Cl} < \text{NO}_3 < \text{SO}_4 < \text{I} < \text{SCN}$; salts of NH_4 in the order $\text{Cl} < \text{SO}_4 < \text{NO}_3$. The series of cations is $\text{Na} < \text{K} < \text{NH}_4$. W. D. L.

Synthesis of carbohydrate in muscle. O. MEYERHOF, K. LOHMANN AND R. MEIER. *Biochem. Z.* **157**, 459-91(1925); cf. *C. A.* **19**, 2073.—The recovery period in muscle is studied. When lactic acid is perfused through frog muscle, some disappears and glycogen increases in amt. If the muscle be suspended in solns. of lactic acid the respiration may increase as much as 100% but the same proportionality is found between carbohydrate formed and O consumed as in normal recovery. The lactic acid formed by fatigue increases the oxidation in muscle, which, in turn, facilitates the removal of the lactic acid. The following substances are without influence upon the respiration:

glucose, fructose, alanine, dihydroxyacetone, asparagine, glycerophosphoric acid and glycolic acid. Ethylene glycol, glyceraldehyde and dihydroxymaleic acid accelerate oxidation slightly, glyceraldehyde about 30%. Acetaldehyde in concns. up to $N/500$ stops the oxidation; methylglyoxal in $N/100$ soln. increases the oxidation slightly. Pyruvic acid increases the oxidation similarly to lactic acid and the carbohydrate formed increases. This conversion of pyruvic acid to glucose entails a reduction and the respiratory quotient should equal 1.2. The respiratory quotient found equals 2.0. There is no decarboxylation of pyruvic acid and none is oxidized. The extra CO_2 varies much, and is less under N than under O, *e. g.*, anaerobic respiratory quotient equals 1.5. The pyruvic acid which disappears is greater than the calcd. amt. The heat of combustion of pyruvic acid is 3172.4 cal. per g. Pyruvic acid in the muscle of warm-blooded animals behaves similarly. In phosphate soln., NH_3 is evolved and urea is formed to an extent which indicates that 15% of the total oxidation is due to the oxidation of protein. However, amino acids are ineffective in raising this NH_3 formation in muscle. The respiration of liver cells, on the other hand, is increased by the presence of amino acids, *e. g.*, of asparagine and alanine, the NH_3 formation with alanine being 3, and of asparagine 10 times the normal formation.

W. D. L.

Studies in carbohydrate metabolism. II. The mutarotation of β -glucose under various conditions. CHRISTEN LUNDSGAARD AND S. A. HOLBØLL. *J. Biol. Chem.* **65**, 305-22(1925); cf. *C. A.* **19**, 3520. **III. The nature of the glucose in the blood of normal individuals.** *Ibid* 323-42.—Blood was dialyzed in collodion membranes (dried in 70% alc.) against 0.9% NaCl soln. for 90 min., coagulation being prevented by the addn. of 2% NaF. The dialyzates were then examd. with the polariscope. The blood from 11 normal persons was examd., 7 men and 4 women varying in age from 18 to 50 years. Of these 3 were investigated both during fasting and after administration of 100 g. of glucose; the others after ingestion of glucose only. A lower $[\alpha]$ than that of α,β -glucose was found in all cases, the values varying from +15.9 to 42.2°. This form of glucose finally reverts to α,β -glucose and the course of the mutarotation is in complete agreement with that found for new-glucose. "It must, therefore, be taken as proved that new-glucose can be detected in the blood of normal persons both while fasting and also after taking glucose. This result, taken together with the previously demonstrated mode of production of new-glucose, supports the view that new-glucose is the first link in the chain of the transformation of glucose in normal carbohydrate metabolism." **IV. The nature of the glucose in the blood of patients with diabetes mellitus and of patients with benign glucosuria.** *Ibid* 343-62.—New-glucose could not be detected in the blood of 9 out of 10 patients with severe or moderately severe diabetes but in 5 of these it was present in the blood 2 hrs. after administration of insulin. It was found to be present in the blood of 2 individuals with benign glucosuria. When new-glucose was found to be present in the blood, it was also possible to demonstrate the removal of glucose from the blood during its passage through the capillaries, in diabetics showing no new-glucose this was not the case. It is, therefore, assumed "that new-glucose is an essential link in normal carbohydrate metabolism and probably the first, and that insulin exerts its action in the organism in conjunction with a substance always or usually present in the muscles, by transforming α,β -glucose into new-glucose which can then be further broken down in the organism." **V. The form of glucose in different body fluids.** *Ibid* 363-9.—New-glucose is present in the spinal, edema, and pleural fluids of individuals with normal carbohydrate metabolism; in the 2 former fluids the concn. is greater than that in blood dialyzate. "This greater concn. may be due to the fact that dialysis is not necessary so that the detns. are made, therefore, before the mutarotation has begun, or to the fact that the concn. of new-glucose is greater in the tissue fluids than in the blood."

A. P. LOTHROP

Chemical findings in the blood of the normal dog. R. L. HADEN AND T. G. ORR. *J. Biol. Chem.* **65**, 479-81(1925).—The following av. results were obtained by the consecutive analysis of the blood of 200 normal dogs which usually had been fasted 48 hrs. before the specimens were obtained: non-protein N 30.8, urea N 11.7, creatinine 1.5, amino acid N (100 analyses) 6.7, sugar 82, chlorides (as NaCl) 468 mg. per 100 cc., and the CO_2 -combining power of the plasma 34.8 vols. %. The % range of the various components is also given.

A. P. LOTHROP

Mucus of the stomach. M. BRESTKIN AND K. BIKOV. *Archiev Biologicheskikh Nauk*, Moscow **24**, 97(1925); *J. Am. Med. Assoc.* **85**, 862.—Mucus, obtained during digestion when its production was stimulated by food, or at other times when stimulated by mech. or chem. irritation, contains a coned. enzyme which can act on the food substances. Digestion *in vitro* takes place more vigorously if mucus is present.

L. W. RIGGS

Physiology of the liver. Present state of our knowledge. A. J. CARLSON. *J. Am. Med. Assoc.* **85**, 1468-72(1925).—An address. L. W. RIGGS

The female sex hormone. II. An analysis of the factors producing puberty. R. T. FRANK, H. M. KINGERY AND R. G. GUSTAVSON. *J. Am. Med. Assoc.* **85**, 1558-9 (1925); cf. *C. A.* **19**, 2523.—Injection of the female sex hormone into immature female white rats in from 3 to 5 days causes opening of the canal and estrual phenomena without the occurrence of ovulation. After a further interval of from 5 to 7 days, the artificially produced puberty may be followed by spontaneous, regular cyclical phenomena consequent to follicle ripening and ovulation. If the threshold of puberty is once crossed, sexual maturity may be maintained spontaneously in immature rats. These findings indicate that puberty results from the elaboration, in sufficient amt., of the female sex hormone, and that the advent of puberty is not due to the removal of an inhibitory influence, such as might be exerted by one or more of the glands of internal secretion, such as the thymus or the pineal gland. L. W. RIGGS

Relation between the sodium chloride content of the blood and the formation of gastric hydrochloric acid. J. MOSONYI. *Magyar Orvosi Archivum* **26**, 407-11(1925).—Since the HCl of the stomach arises from the chlorides of the blood, a diminution of these chlorides occurs after stomach digestion. Expts. calcd. to apply the decrease of chlorides of the blood to the diagnosis of various gastric secretion anomalies are in progress. L. W. RIGGS

The increase of the carbon dioxide content of the blood in the course of digestion. H. TANGL. *Magyar Orvosi Archivum* **26**, 412-4(1925).—During the digestion which follows a period of starvation the loosely combined CO₂ content of the blood is increased about 10%. This increase is chiefly in connection with the HCl secretion. With this increase of CO₂ there is also an elevation of the CO₂ tension of the alveolar air. L. W. RIGGS

Lactic acid of blood under respiration. BINET AND COLLAZO. *Médecine*, Paris, **6**, 924(1925); *J. Am. Med. Assoc.* **85**, 1761.—Blood was drawn simultaneously from the right heart and the carotid of chloralosed dogs. An excess of lactic acid by 3 to 11 mg per 100 cc. of blood was manifest in the blood of the right heart, as compared with that of the left. Asphyxia increased the content of lactic acid 32 mg. before, and 55 mg. 6 min. after, the beginning of asphyxia. The increase of lactic acid was still manifest for a certain time after the respiration became normal. Panting for 10 min. reduced the amt. of lactic acid from 36 to 20 mg. L. W. RIGGS

Distribution of insulin in the normal and pancreatic diabetic dog. MARTIN NOTHMANN. *Arch. exptl. Path. Pharm.* **108**, 1-63(1925).—The pancreas, liver, muscle, blood, spleen, kidney, heart, lung, thyroid, salivary gland, brain and testis of normal dogs were tested for the presence of substances which, acting like insulin, would reduce the blood sugar in rabbits. With one exception (the spleen of one dog) all organs yielded active exts., whose effects were identical with those of insulin. In the rabbit deprived of food they caused a fall in blood sugar and the glycogen content of the liver and musculature of normal rabbits was diminished. In animals with pancreatic diabetes the exts. reduced the blood pressure and simultaneously diminished the sugar output through the urine. Exts. prepd. from the tissues of dogs with pancreatic diabetes were without insulin-like action with the exception of those prepd. from liver tissue. In these animals the amt. of active principle in the liver was but slightly less (4.03 units per 100 g. of fresh liver) than that of the liver of the normal animal (4.44 units). To a high degree the amt. present in the liver is independent of the glycogen content of the liver and of the time after extirpation of the pancreas. Ether narcosis does not modify the content in insulin-like material. The principle derived from the liver of pancreatic diabetic dogs markedly reduces the glycogen content of the liver and muscle of normal rabbits and may lead to convulsions. Injected intra-arterially it changes the blood sugar relationships in both the arterial and venous blood. Injections of the liver ext. allowed dogs to live for 24 days after complete removal of the pancreas. Here, blood sugar was reduced, as was sugar excretion, but the glycogen content of the animal remained normal. Apparently the insulin-like substance of the dog with pancreatic diabetes is identical in all respects with that of normal dogs and with insulin. G. H. S.

Mineral metabolism. INOSUKE NOGUCHI. *Arch. exptl. Path. Pharm.* **108**, 64-72 (1925).—In making detns. of the K, Ca and Na of the serums of normal persons and of those with renal disease it is essential that the serum be sepd. from the red blood cells as promptly as possible if the K value is to have significance. With Ca and Na this is less important. After administration of KCl the K of the serum is considerably increased, while the Ca may show a simultaneous reduction or the Na may be diminished

Administration of NaHCO_3 to two cases of chronic nephritis caused an increased blood Na in both and a fall in K in one. Novasurol injection increased the K but did not materially change the Ca and Na, indicating that the effect is not directly upon the kidney but rather upon a change in relations between the tissues and the blood. **II. Mineral metabolism in patients with renal disease.** *Ibid* 73-7.—In patients with chronic renal disease considerable increases in the serum K were observed at times, associated with particularly severe disturbances. The same increase in serum K is observed in dogs deprived of kidney tissue. Such an increase in K is not referable to an output of K by the erythrocytes; it is derived from the tissues. G. H. S.

The opposite action of high and low calcium concentrations on the sugar output of the isolated frog liver. E. GEIGER AND L. MÜLLER. *Arch. expl. Path. Pharm.* 108, 238-47(1925).—The influence of Ca upon the sugar output of the isolated frog liver depends upon 2 factors. There is a stimulating factor associated with the intact liver, which must have the same basic mechanism as the action of adrenaline. The inhibitory factor becomes apparent in the tissue paste expt., being associated with a reduction in the permeability of the cells. With low concns. of Ca the favoring component can be measured, but when the concn. is increased the inhibitory effect becomes dominant. G. H. S.

Effect of loss of water through osmosis upon the function of nerves and muscles. M. BÜRGER AND L. LENDLE. *Arch. expl. Path. Pharm.* 109, 1-21(1925).—The muscles and the peripheral nerves of frogs become paralyzed when placed in hypertonic dextrose solns. contg. Ringer salts. The time of onset of the paralysis is dependent upon the concn., and within limits is also dependent upon the extent of the osmotic water loss. The paralysis passes over into a state of hyperirritability. With a given concn. of dextrose the paralysis of the peripheral nerves develops somewhat later than does that of the muscles, and as the paralysis develops the nerve loses relatively more water than does the muscle. Up to a point where functional damage is too great the muscle deprived of water can be restored - a reversible reaction—but the nerve, which loses water more slowly, if functionally impaired cannot be completely restored. In muscle the max. wt. loss and the paralysis are simultaneously occurring phenomena; with nerve the max. loss in wt. considerably precedes the paralysis. G. H. S.

Function of the parathyroids. I. The parathyroids and the thyroids in their relation to the healing of fractures and the calcification of bones. SHIGESHI OGAWA. *Arch. expl. Path. Pharm.* 109, 83-107(1925).—The thyroid impairs the healing of fractures, while the parathyroids favor the process. In a similar way the hormones of these glands show an antagonism in that Ca deposition is favored by that of the parathyroids and inhibited by that of the thyroids. **II. As a heat-regulating organ.** *Ibid* 300-17.—Extirpation of both the thyroid and parathyroid glands results in a disturbance to the heat-regulating mechanism. In rats and in rabbits the removal of the parathyroids alone interferes with heat control. The injection of parathyroid preps. somewhat compensates for the loss in regulatory function in animals deprived of both thyroid and parathyroid glands, while the injection of thyroid prep. fails to prevent the disturbance. In animals deprived of the parathyroids, as in those lacking both the thyroids and the parathyroids, warming is followed by the onset of intense convulsive attacks, but in rats lacking thyroid substance these attacks do not occur if parathyroid tissue remains intact. Thus, the hormone of the parathyroid, but not that of the thyroid, is involved in heat regulation. G. H. S.

Methemoglobin reversion. II. Perfusion experiments. KYUICHI SAKURAI. *Arch. expl. Path. Pharm.* 109, 198-213(1925); cf. C. A. 20, 66. In the perfusion of the isolated surviving cat lung with defibrinated blood contg. methemoglobin a significant reversion of the methemoglobin to oxyhemoglobin occurs. The percentage reversion depends upon the conditions of the expt. With a perfusion period of from 94 to 103 min. the reversion amounts to 26.1% in the ordinary perfusion of the isolated lung under air respiration; with H respiration the av. is 26.5%; with the addn. of Na thiosulfate the av. is 36.5%; in combined perfusion of lung and liver the av. is 36.6%, while with simultaneous lung and liver perfusion with the addn. of Na thiosulfate to the perfusion fluid, it is 44.8%. The reversion process is not modified by the presence or absence of O. Na thiosulfate intensifies the process. Liver and lung together have a greater effect than lung alone. The max. restitution never exceeds 50%. These values hold for blood which contains at the beginning of the expt. not more than 60% of methemoglobin. When the initial content is increased above 70% the process of reversion is rendered more difficult. G. H. S.

Central regulation of the blood sugar. D. DE LA PAZ. *Arch. expl. Path. Pharm.* 109, 318-31(1925).—Within the brain-stem there is, apparently, a blood-sugar-regulat-

ing center, the control of which is related to the cerebrum. If the sugar concn. falls below normal through diln. this center stimulates sugar production, while in hyperglucemia it apparently inhibits or diminishes the production of sugar. The adrenals are of significance in blood sugar regulation only insofar as they are in connection with this center and are influenced by it. Apparently diln. of the peripheral blood stimulates the center in a reflex manner, since an intrajugular injection often has a greater effect than does an intra-arterial injection. G. H. S.

The frog membrane as an organ of water resorption. I. Irreciprocal permeability. V. BAUER. *Arch. ges. Physiol.* (Pflüger's) **209**, 301–32(1925).—As regards water and salt solns. the frog membrane manifests a one-sided reaction, the normal direction of its continuous water transport being from outside inward. Many of the features of the irreciprocal permeability as it has been observed are due to the fact that the media placed upon the opposing surfaces of the membrane do not conform to the normal physiol. conditions, the result being that the membrane is damaged. Distd. water quickly causes injury, making the membrane irreversible, and with a prolonged contact killing it, the effect being of greater intensity when in contact with the physiol. inner side. Nevertheless, it does impair the functional activity of the outer side through an excessive action on the mucous glands. These glands are also injured by hypertonic saline solns. Sugar solns. also lead to very considerable changes in the membrane, rendering it thicker. G. H. S.

Humoral transmission of stomach-vagus stimulation in rabbits. R. BRINKMAN AND J. V. D. VELDE. *Arch. ges. Physiol.* (Pflüger's) **209**, 383–6(1925); cf. *C. A.* **19**, 1887.—If the carotid blood of a rabbit is removed immediately after vagal stimulation and injected intravenously into a normal rabbit it induces a typical vagal gastric contraction. G. H. S.

Hyperthyroidization experiments in dogs. I. Physiological evaluation of thyroid preparations. R. H. MARK. *Arch. ges. Physiol.* (Pflüger's) **209**, 437–64(1925).—Thyroid preps. cause a definite increase in the N excretion per kg. of body wt. The urea elimination parallels the total N excretion, but the NH_3 excretion is not materially changed. Creatinuria also occurs after thyroid has been administered for a longer time. Diuresis is increased, but it is by itself not a measure of the value of a thyroid prep. As regards loss in wt., iodothylin is more effective than fat-free thyroid and this in turn is about twice as effective as thyroid ext. The pulse rate is augmented after the oral administration of thyroid preps. Apparently the I content of the preps. is not the factor which det. their characteristic effects. **II. Action of thyroid preparation in the adult.** *Ibid.* 693–701.—With hyperthyroidization the amt. of N excreted per kg. of body wt. is diminished, i. e., the N balance becomes positive. As a rule the loss in wt. is slight. The pulse rate usually shows no disturbance, but in some cases it is diminished. In young dogs the particularly noteworthy change is a considerable decrease in the diuresis which always occurs. These observations in young dogs correlate well with the observed fact that children react to thyroid less intensely than do adults. G. H. S.

Irreciprocal permeability of animal membranes for gases: frog membrane and frog lungs. ERNST WERTHEIMER. *Arch. ges. Physiol.* (Pflüger's) **209**, 493–8(1925).—Nascent O passes through the frog membrane from the outside inward, but not from the inside outward. CO_2 passes outward from within, but not in the opposite direction. In the lung CO_2 passes inward only, while O goes to the inner side much more readily than from inside outward, as is also the case for NH_3 . G. H. S.

Hemolysis studies. II. Salt action and saponin hemolysis. RUDOLF MOND. *Arch. ges. Physiol.* (Pflüger's) **209**, 499–511(1925).—Although in general at various H-ion concns. K increases the hemolysis, with other ions there is a noteworthy contrast in the action of SO_4 and Ca. In the neighborhood of the isoelec. point SO_4 ions inhibit the hemoglobin outgo from red cells while Ca ions favor it, but as the reaction is removed from the isoelec. point it inhibits the dissolving action of the OH ions. For every salt a characteristic curve of hemolysis occurs with the passage of time. These curves intersect each other to some degree so that a reversal of ion action occurs as the period of action is extended. Here also the opposing action of SO_4 and Ca appears at different p_{H} values. The SO_4 inhibits hemolysis; Ca favors it in the beginning while later Ca causes an outspoken retardation aside from the H and OH ions. The ions of the neutral salts alter the permeability of saponin-treated blood corpuscles in an entirely opposite manner from that of normal cells. This is particularly true for the rate of hemolysis in Na_2SO_4 and CaCl_2 . In an alk. reaction, except for CaCl_2 solns., saponin in low concns. markedly inhibits hemolysis. G. H. S.

Role of the pylorus in pancreatic secretion. ANNA TONKICH. *Arch. ges. Physiol.*

(Pflüger's) 209, 512-5(1925).—The ordinary trophic action on the pancreas, *i. e.*, the increase in the N content in the juice after the passage of a milk-cream-butter mixt. into the duodenum persists even after the fundus is sepd. from the pyloric portion of the stomach. This result does not occur if the mixt. is introduced into the duodenum and the latter is sepd. from the pylorus. Obviously the pyloric region must be considered as the point of origin for the trophic impulse in pancreatic secretion to fat.

G. H. S.

Chemical regulation of the heart beat by the liver. LEON ASHER. *Arch. ges. Physiol.* (Pflüger's) 209, 605-6(1925).—Fluids which have been perfused through the liver acquire thereby the property of modifying the heart beat, the effect resembling that of adrenaline.

G. H. S.

Internal secretion of the pineal body of rats. ERNST HOFMANN. *Arch. ges. Physiol.* (Pflüger's) 209, 685-92(1925).—The pineal gland was completely removed by cauterization and subsequent events showed that these glands have no noteworthy influence upon the increase in wt., on growth in length, in fat development, or on sexual maturity, indicating that there is no connection between the pineal organ and the germinal glands. Heat regulation was unaffected.

G. H. S.

G—PATHOLOGY

H. GIDEON WELLS

The effect of sodium ricinoleate upon bacterial toxins and the value of soap-toxin mixtures as antigens. W. P. LARSON, R. D. EVANS AND E. NELSON. *Proc. Soc. Exptl. Biol. Med.* 22, 194-6(1924).—The detoxifying action of the Na salts of various fatty acids was tested by adding an equal quantity of a 1% soln. of the soap to tetanus and to diphtheritic toxin. The soaps of oleic, stearic and palmitic acids did not detoxify. The soaps of lauric, myristic, cinnamic and hendecenoic acids detoxified to a certain extent. Na ricinoleate had a marked detoxifying action; 0.2 cc. of a 1% soln. prevented symptoms in a guinea pig when sufficient tetanus toxin to cause death was given. Detoxifying soaps form clear solns. in physiol. NaCl soln.; they dialyze readily through hardened collodion sacs and they markedly depress the liquid air surface tension. Colloidal solns. when added to the soap prevent the detoxifying action, which seems to be an adsorption phenomenon. Immunizing tests showed that the toxin is imprisoned unchanged, and is slowly released from the soap-toxin mixt.

C. V. B.

Optical desensitization with warm-blooded animals. T. AWOKI. *Biochem. Z.* 158, 337-49(1925).—The characteristic symptoms which appear in white mice that have been injected with hematoporphyrin when they are exposed to strong light were abolished when the mice had been injected also with inactivated human serum. Desensitization was not induced by the reducing agents $\text{Na}_2\text{S}_2\text{O}_3$, $\text{Na}_2\text{S}_2\text{O}_4$, Na_2SO_3 , glucose or sucrose. Urethan diminished the irritation following light exposure but not the later symptoms that lead to death.

F. A. CAJORI

The fat-cholesterol content of the blood of patients with Basedow's disease. H. I. BING AND H. HECKSCHER. *Biochem. Z.* 158, 403-16(1925).—The fat and cholesterol in the blood of patients with hyperthyroidism was found to be low (0.06%). After medical or surgical treatment it returned to normal (0.12%).

F. A. CAJORI

The fat-cholesterol content of the blood in thyroidectomized horses. H. HECKSCHER. *Biochem. Z.* 158, 417-21(1925).—The fat and cholesterol content of the blood was found to be higher in thyroidectomized horses than in normal horses and rose to a higher level after fat feeding in the thyroidectomized animals than in the normals. **The fat-cholesterol content of the blood of cretins.** *Ibid.* 422-7.—The fat and cholesterol in the blood of grown or half-grown cretins were higher than those in normal, though in cretins who were still children, normal values were usually found.

F. A. CAJORI

Factors concerned in the preparation of diphtheria toxoid. P. J. MOLONEY AND C. B. WELD. *Trans. Roy. Soc. Can.* 19, Sect. V, 111-6(1925).—The paper gives results dealing with the influence of various factors on the modification of diphtheria toxin by HCHO. A satisfactory method for the production of diphtheria toxoid is detailed.

A. T. CAMERON

The Ramon test: diphtheria toxin-antitoxin flocculation. P. J. MOLONEY AND C. B. WELD. *Trans. Roy. Soc. Can.* 19, Sect. V, 117-23(1925).—The indicating tube in the Ramon test does not always represent a balanced mixt. of toxin (or toxoid) and antitoxin, but depending on the serum used may be neutral, toxic, or antitoxic. The test cannot be used as a measure of antitoxin as defined in Ehrlich units, but may be used as a rough guide prior to animal testing. It perhaps can be used to det. whether or not a toxoid (or anatoxin) possesses any immunizing value. It can be used as a

guide in detg. changes of antigenic value of toxoid undergoing modification.

A. T. CAMERON

Some chemical properties of diphtheria toxoid. P. J. MOLONEY AND C. B. WELD. *Trans. Roy. Soc. Can.* 19, Sect. V, 125-7(1925).—Toxoids may be kept for months at room temp. without deterioration. Purified toxoid does not appear to be so stable. It is protein-like, gives a positive but weak biuret, positive Millon, xanthoproteic and Hopkins-Cole reactions and contains unoxidized S. About 0.5 mg of the dried product in soln. is sufficient to bring about a state of active immunity. This contained 11% N (corrected for ash).

A. T. CAMERON

The clinical assaying of insulin and the insulin requirement. R. M. WILDER. *Endocrinology* 8, 630-8(1924).—In studies on uncomplicated cases of diabetes it was found that the insulin prep. previous to Oct. 1923 was assayed quite uniformly at a glucose equiv. of 1.7 g. while that prep. since that time has not been as accurately standardized but is equiv. to approx. 2.0 g. of glucose per unit. The glucose equiv. of insulin is altered on high-protein and carbohydrate diets while starvation diminishes the insulin requirement. The amt. of glucose oxidized by a unit of insulin is markedly lowered by acute complications especially infections. Insulin must act directly on glucose with a definite chemical reaction since the glucose equiv. in uncomplicated cases of diabetes did not vary with patients of different wt. and age. H. J. D., Jr.

"Uricolytic index" in diabetic dogs. EINAR LANGFELDT AND JÖRGEN HOLMSEN. *Biochem. J.* 19, 724-6(1925).—"Uricolytic index" (U. I.) expresses the percentage of the total of the uric acid N plus allantoin N represented by the allantoin N. The U. I. of normal dogs is not altered when fed with 5 g. nucleic acid, the U. I. of diabetics decreases under these conditions, indicating a diminished power to destroy uric acid.

BENJAMIN HARROW

Some metabolic differences, following X-radiation, between normal rats and rats immune to Jensen's rat sarcoma. E. C. DODDS, WILFRED LAWSON AND J. C. MOTTRAM. *Biochem. J.* 19, 750-2(1925).—"Immune" animals do not differ from normal animals in the non-protein N or urea blood content prior to X-radiation. After the X-radiation, the "immune" animals show a marked reduction in the blood-urea content (it falls from a normal value of 35 mg. per 100 cc. to about 14 mg. per 100 cc.). B. H.

Blood and tissue changes in cancer with reference to diagnosis and treatment. J. A. SHAW-MACKENZIE. *J. Trop. Med.* 28, 297-302(1925).—Review and discussion.

FRANCES KRASNOW

Studies on the morning alkaline tide of the urine in normal persons and in patients with nephritis. J. E. MCCORVIE. *J. Clin. Invest.* 2, 35-66(1925).—Normal persons showed the morning diuresis and alk tide, while nephritics reacted like the normal or showed a limitation in one or both of the features. A high initial alkaline tide may be followed by an acid tide in abnormal persons. An acid tide is of serious import. The p_H parallels the alk. % and the urinary CO_2 . The phosphate content of night urine of nephritics is much lower than that of normals.

LOUIS LEITER

Studies in liver function. II. The concentrations of cholesterol, bile acids and pigments of duodenal contents in health and disease of the liver or its ducts. C. W. MCCLURE AND ELDORA VANCE. *Bost. Med. Surg. J.* 192, 433-7(1925); cf. *C. A.* 19, 3505.—The estn. of these substances in duodenal contents after the introduction of $MgSO_4$ was used as a functional test of the liver. While there are certain sources of error it seemed justified to conclude that the liver function is deranged in lesions involving either the parenchyma of the liver or its blood supply and in chronic cholecystitis. $MgSO_4$ introduced into the duodenum may affect the functional state of the liver. Bile in the duodenum after $MgSO_4$ lavage undergoes very little modification as the result of action on the part of the gall bladder.

JULIAN H. LEWIS

Experimental transplacental infection by filterable tuberculosis virus. A. CALMETTE, J. VALTIS, L. NEGRE AND A. BOQUET. *Compt. rend.* 181, 491-3(1925).—The authors were able to transmit tuberculosis to the progeny of guinea pigs after injection of bacteria-free filtrates of cultures of *B. tuberculosis*. The new-born guinea pigs died of the infection without evident infection of the placenta of the mother, which indicates that the filterable elements of the tubercle bacillus passed on through the placenta to the fetus without causing active infection of the placenta.

G. F. REDDISH

Comparative studies on the metabolism of normal and malignant cells. J. B. MURPHY AND J. A. HAWKINS. *J. Gen. Physiol.* 8, 115-30(1925).—A classification of tissues on the basis of their metabolism does not correspond to the biol. grouping. These studies do not support the conclusions of Warburg (*C. A.* 19, 2702). C. H. R.

The albumin reaction and the tyrosine reaction of sputum. ANDRÉ TERCINET. *Bull. sci. pharmacol.* 32, 524-7(1925).—The ninhydrin reaction and the action of an

oxidase prep'd. from *Russula delicata* were studied. These reactions are not sufficient to establish a diagnosis of tuberculosis. L. W. RIGGS

Immunizing properties of dysenteric toxin. J. DUMAS, G. RAMON AND SAÏD BILAL. *Compt. rend.* **181**, 198-9(1925).—The anatoxin prep'd. from the dysenteric bacillus of Shiga caused the production of immunizing antibodies in the rabbit, in the horse and in man. L. W. RIGGS

The rose bengal test for liver function. Rate of elimination from the circulation of man. W. J. KERR, G. D. DELPRAT, N. N. EPSTEIN AND MAX DUNIEVITZ. *J. Am. Med. Assoc.* **85**, 942-6(1925).—The dye fulfils the following requirements: (a) it is nontoxic in the amts. necessary for the tests; (b) it is a crystalloid; (c) it is eliminated through the liver; (d) it remains in the circulation for a sufficient length of time to allow detns. of the dye in the plasma to be made. Patients with definite cirrhosis or other extensive liver disease show a marked retention of the dye in the circulating blood. Obstruction of the biliary passages causes a retention of the dye, but in such cases there are other clinical evidences of such obstruction. In all other cases studied the results are within normal limits. L. W. RIGGS

Pathologic physiology of liver in relation to intoxication and infection. E. L. OPIE. *J. Am. Med. Assoc.* **85**, 1533-7(1925), cf. following abstract.—The liver by means of the peculiar endothelium of its sinusoids fixes insol. morg. particles, such as bacteria and substances in colloidal suspension, and perhaps by the same means many substances dissolved in the plasma. With immunization, the liver shows increased ability to fix bacteria and foreign proteins and to render them harmless. The liver removes from the portal blood many injurious agents which enter from the gastro-intestinal tract and prevents their entrance into the systemic circulation. Fixation of injurious substances may cause destructive changes in the liver and permanent lesions of the organ. L. W. RIGGS

The evaluation and treatment of disturbed liver function. C. W. McCURE, W. L. MENDENHALL AND MILDRED E. HUNTSINGER. *J. Am. Med. Assoc.* **85**, 1537-40 (1925); cf. preceding abstract.—The functional condition of the liver is estd. with oleic acid and the resulting bile is obtained by means of a duodenal tube. This bile is analyzed for bilirubin, total pigments, bile acids and cholesterol. The results show that $MgSO_4$ has a pronounced effect on the functional activity of the liver in man and animals, increasing or decreasing that activity according to the amt. of $MgSO_4$ which reaches the liver. Under properly controlled conditions $MgSO_4$ can modify favorably a functional state of the liver which has been deranged by disease, but its successful use requires much experience. L. W. RIGGS

Hydrogen-ion concentration of the blood in atrophic and dyspeptic infants. Z. BOKAY. *Magyar Orvosi Archivum* **26**, 381-3(1925).—The measurements of p_H gave partly normal and partly acid values. Atrophy is not followed by acidosis as a consequence, but creates a tendency to acidosis. A pronounced alkalosis occurred in one case of pylorus spasm and probably was due to loss of acid by continuous vomiting. L. W. RIGGS

Immunizing antigen of the pneumococcus. III. The purification of the water-soluble antigen. WM. A. PERLZWEIG AND C. S. KEEFER. *J. Exptl. Med.* **42**, 747-52 (1925).—Actively immunizing fractions of protein nature have been isolated from broth culture filtrates of pneumococcus Type I by ultrafiltration, pptn. at a definite H-ion concn. (p_H 4.1) and the sepn. of a sol. pterate fraction. The method appears to be suitable for the initial purification of this antigen. C. J. WEST

FREUND, ERNST, AND KAMINER, GISA: *Biochemische Grundlagen der Disposition für Karzinom*. Vienna: Julius Springer. Paper, M. 4.50.

II—PHARMACOLOGY

ALFRED N. RICHARDS

The effect of some intermediary products on the gas metabolism of rabbits. V. LAUFBERGER. *Biochem. Z.* **158**, 260-77(1925).—The respiratory quotient of rabbits was detd. after various substances were administered by stomach sound. EtOH and dihydroxyacetone were found to be completely combustible and exerted a carbohydrate-sparing action. Succinic acid, pyruvic acid and lactic acid were not completely burned to CO_2 and H_2O in the body but underwent further chem. change to other materials. F. A. CAJORI

The effect of insulin on the water-salt economy of non-diabetic organisms. H. VOLLMER AND J. SEREBRIJSKI. *Biochem. Z.* **158**, 366-94(1925).—In normal fasting rabbits, insulin injection caused an increase in blood Cl and diln. of the blood. These

changes were found to be associated with maintenance of osmotic regulation of the blood and also are involved in insulin action
F. A. CAJORI

The specific action of carbonic acid on the respiratory center of men and rabbits. ISTVAN HETÉNYI, GYULA HOLLÓ AND ISTVAN WEISS. *Biochem. Z.* **160**, 242–5 (1925).—Injection of 20 cc. NaHCO_3 soln. in man was followed by a rise in blood p_{H} and plasma bicarbonate and a fall in alveolar CO_2 . The stimulating action on the respiratory center was due not to free CO_2 but to HCO_3 ions. This was further confirmed by injecting rabbits with NaHCO_3 and H_2CO_3 of blood reaction or slightly more acid and noting that the stimulatory action of H_2CO_3 was not dependent on an alk. blood reaction.
F. A. CAJORI

The antagonistic effect of hypophysis and insulin on diuresis. N. KLISSIUNIS. *Biochem. Z.* **160**, 246–9 (1925).—The diuresis following the giving of 500 cc. of H_2O to dogs was diminished by injection of hypophysis ext. When insulin was administered simultaneously with hypophysis ext., diuresis occurred unchecked. Insulin alone had no effect on the diuresis.
F. A. CAJORI

The influence of some substances on the secretion of Harder's glands. S. BEL FANTI. *Biochem. Z.* **158**, 435–42 (1925).—Muscarine Me_4NI , Et_3NHIO_3 , and ecl serum when injected intravenously caused a milky secretion of Harder's glands, located in the eyelid of the guinea pig. Synthetic muscarine, $(\text{NH}_4)_2\text{SO}_4$, pilocarpine and betaine did not stimulate these glands to secretion.
F. A. CAJORI

The treatment of disease with heavy metals and bactericidal agents. W. E. DIXON. *Tubercle* **7**, 1–6 (1925).—A review of recent chemotherapeutic attempts in tuberculosis with Cu salts, Au salts and sanocrysin.
H. J. CORPER

Chemotherapeutic experiments on tuberculous guinea pigs. FELIX KLOPFSTOCK. *Z. Tuberk.* **40**, 119–22 (1924).—Subcutaneous injection of "Elektrocuprol" (Heyden) into tuberculous guinea pigs initiated 2 weeks after infection with a human strain resulted in a rapid emaciation and death from intercurrent diseases without any appreciable effect upon the disease in the animals. "Elektrokollargol" and "Elektroferrol Heyden" resulted in an increase of life duration of the treated animals. "Lecutyl" ointment byunction, chaulmoogra oil and the propyl esters of the chaulmoogric fatty acids were without influence upon tuberculous guinea pigs.
H. J. CORPER

Experiments with krysolgan in tuberculosis. TORU KOZUMI. *Z. Tuberk.* **41**, 109–19 (1924).—Krysolgan injections had no influence upon tuberculosis in guinea pigs or rabbits. A 1% soln. for 4 hrs. did not kill tubercle bacilli *in vitro*. Such action as is attributable to krysolgan is believed to be non sp. and its use in man generally is not justified.
H. J. CORPER

The effect of thyroxin on the respiratory and nitrogenous metabolism of normal and myxedematous subjects. W. M. BOOTHBY, I. SANDIFORD, K. SANDIFORD AND J. SLOSSE. *Ergebnisse Physiol.* **24**, 728–56 (1925).—Following the administration of thyroid or thyroxin to 2 myxedematous and one normal subject, there is a temporary rise in N excretion which indicates an increased catabolism of stored protein but which is without effect on true endogenous protein metabolism. With the subject originally in N equil. and kept on a const. protein intake, there is an immediate large increase in N elimination with a correspondingly large negative N balance during the period when the heat production is being elevated on account of the administration of thyroxin; however, after the heat production has reached its max. and is maintained there by small doses of thyroxin, there is a gradual decrease in N output for 2 to 4 weeks until it has reached its former value. Creatinine and uric acid elimination are unchanged following thyroxin although there is a slight excretion of creatine during the period of high N output. The loss in wt. of the subjects which was largely water following thyroid ingestion when compared with the N loss indicates the breakdown of an albuminous fluid of about 2% N which is probably responsible for the edema of myxedema. There were no changes in the non-protein N or other N partition products in the blood of the normal after thyroxin, in the myxedematous patients an increased blood urea resulted. The decay curves showing the effect of thyroxin on the basal metabolism with their mathematical formulas are given.
H. J. DEUEL, JR.

Glucemia and glucolysis in phlorhizin diabetes treated with insulin, with special reference to the protein sugar. MICHELE BUFANO. *Arch. farm. sper.* **40**, 1–22 (1925).—Detns. of free and combined sugar in the blood of phlorhizinized rabbits before and after placing the samples 1 hr. in the thermostat at 36° were made for the purpose of ascertaining the effect of insulin on glucemia and on subsequent glucolysis. Phlorhizin alone has no effect on the combined sugar, while with insulin irregular variations were noted. In neither case was any effect on glucolysis of combined sugar observed as compared with that of the normal animal. The free sugar in the blood is greatly di-

minished by the phlorhizin treatment, and still further diminished when this is followed by injection of insulin.

A. W. DOX

Pharmacological investigation of a bismuth colloid. ALFREDO CHISTONI. *Arch. farm. sper.* **40**, 23-48(1925).—By heating Bi phosphate with NaOH and albumin a colloidal prepn. of Bi is obtained, which is claimed to be more stable and of a higher degree of dispersion than other preps. of colloidal Bi on the market. For optimum stability the prepn. should contain 1% Bi. Pharmacological tests show that only a slight flocculation occurs in the tissue in the region of a subcutaneous injection or in the various organs of the body, with the possible exception of the lung. Elimination is principally through the kidneys, the intestinal wall and the salivary glands.

A. W. DOX

Cardiazole, a new water-soluble analeptic suitable for intravenous application. I. K. F. SCHMIDT. II. F. HILDEBRANDT. III. L. KREHL. *Klin. Wochschr.* **4**, 1678-80(1925).—I. Cardiazole is pentamethylenetetrazole, $\text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{N} \cdot \text{N} \cdot \text{N}$.

white, m. 57-8°, very sol. in H₂O and in most org. solvents. Its aq. soln. can be kept indefinitely and may be autoclaved. With concd. HCl in a sealed tube at 250° it gives N₂, CO₂ and H₂NCH₂CH₂CH₂CH₂CH₂NH₂. HgCl₂ ppts. from aq. solns. C₆-H₁₀N₄ HgCl₂, white, m. 175°, sol. in 800 pts. H₂O. II. The pharmacol. behavior of cardiazole is similar to that of camphor. It is, however, absorbed so rapidly that the action is almost as prompt on subcutaneous as on intravenous application. It is a powerful heart stimulant (frog and rat). Concns. (in the perfusion fluid) up to 0.5% are not toxic. Hearts poisoned with CHCl₃, CCl₃CHO or choline are promptly revived with cardiazole. It has no inhibitory action on smooth muscle. III. The therapeutic subcutaneous dose is 0.1 g. The injection is usually painless; absorption is very rapid. Cases of cardiac collapse are revived.

MILTON HANKE

A simple method for the biological assay of hypophysis preparations. S. LOEWEN AND M. ILSON. *Klin. Wochschr.* **4**, 1692(1925).—Small pieces of frog skin, immersed in a nutrient medium, react toward hypophysis ext. exactly as does the intact frog. The skin becomes deeply pigmented. Examn. of such skin sections under the microscope shows that this coloration is caused by an excitation of the dormant pigment cells with a consequent pigmentation. A max. conversion of dormant into active pigment cells occurs in 15 min. The percent conversion of dormant into active, fully pigmented cells, in 15 min., is directly proportional to the strength of the prepn. A good prepn. gives 100% conversion. This method of assay is preferable to the uterus contraction method because the reaction is specific for hypophyseal ext.

MILTON HANKE

The influence of injections of heavy metals on diabetes mellitus. ERICH SCHILLING AND RUDOLF ARNOLD. *Klin. Wochschr.* **4**, 1818-9(1925).—Compds. of Fe, Hg, Ag and Bi were tried. The results were not unidirectional; so no definite conclusions can be drawn.

MILTON HANKE

The antagonism between insulin and adrenaline. E. BODEN AND F. WANKELL. *Klin. Wochschr.* **4**, 1823(1925).—Insulin markedly increases the rate and intensity of the contractions of an isolated intestine. Adrenaline is completely antagonistic; atropine is transitorily antagonistic. Insulin and adrenaline give identical results with a Laeven-Trendelburger frog prepn.; both decrease the rate of flow from 18 to 4 drops per min. In this respect, then, they are not antagonistic.

MILTON HANKE

Inhibition of exudation by pituitrin and by various other substances that act upon the reticulo-endothelial system. PAUL SAXL AND FERDINAND DONATH. *Klin. Wochschr.* **4**, 1866-7(1925).—Pituitrin and *arsphenamine*, by acting upon the reticulo-endothelial system, inhibit the exudation, and to a smaller extent the production of edema, in cases of mustard oil conjunctivitis. *Atrillavine* does not inhibit exudation but does inhibit the edema.

MILTON HANKE

The action of extracts of bilberry leaves on depancreatized dogs. E. EPPINGER, R. E. MARK AND R. J. WAGNER. *Klin. Wochschr.* **4**, 1870-1(1925).—Depancreatized dogs were injected with an ext. of bilberry leaves. The excretion of sugar is reduced, in some cases, to zero. The Minkowski quotient is very low. The animals live as long as treatment is continued. Blood sugar is high.

MILTON HANKE

Demonstration of circulating heavy metals. T. KOMIYAMA. *Klin. Wochschr.* **4**, 2012-3(1925).—A suspension of S was injected into one thigh (mouse) and a suspension of an insol. salt of Pb, Bi or Hg was injected into the other thigh. The S depot began to turn black within 12-24 hrs. as a result of the formation of metallic sulfide. After 36-48 hrs. the metallic salt depot began to turn black. Evidently, both the metallic ion and the S must be circulating in a form such that metal sulfide can form. If a

salve contg. a Bi salt is massaged into the area just above the S depot, the outer epidermis becomes dark-colored within 6 hrs. After 2 days the S depot is also colored. When the salve is massaged into the skin of the right leg, the S depot being in the left leg, a coloration of the skin below the massaged area does not occur; but the S depot becomes dark colored within 12-24 hrs. Metal salts, absorbed as salve, circulate in the blood for 3-4 days. If the salve is removed after 12 hrs. and S injected, remotely, at different time intervals, the S depot will become dark-colored within 12 hrs. even 3-4 days after the salve has been removed.

MILTON HANKE

Can strontium replace calcium pharmacologically? S. HIRSCH AND ALB. OPPENHEIMER. *Klin. Wochschr.* **4**, 2015-6(1925).—Frog hearts that have been brought to a standstill by immersion in 0.85% NaCl soln. begin to beat when they are immersed in a Ringer soln. in which the Ca has been replaced by Sr. In this respect the Sr is only 0.5 as effective as Ca. The restorative action of Sr is transitory. An isolated rabbit heart, when perfused with a Sr-contg. Ringer soln. (no Ca), shows a reduction in the size of the excursion, elongation of the systole, diminution of the diastole and an occasional arrhythmia. Sr is 0.5 as active as Ca in the perfusion expt. and its action is transitory. Sr cannot replace Ca.

MILTON HANKE

The effect of calcium and potassium ions on the pituitrin blood-sugar reaction. E. KYLIN. *Klin. Wochschr.* **4**, 2068(1925).—Pituitrin elevates the blood sugar. KCl (0.2 g.) augments and CaCl_2 (1.0 g.) reduces the action of pituitrin in this respect. The salt injection preceded that of the pituitrin by 1 hr.

MILTON HANKE

Action of arspenamine on the frog heart. F. JACOBSON. *Klin. Wochschr.* **4**, 2068-9(1925).—Neoarsphenamine and K are identical in their action upon the isolated frog heart, the diastole is increased and the systole is correspondingly decreased. This effect can be promptly removed by the addition of Ca. The toxic effects of arsenic prepns. can be avoided by injecting CaCl_2 along with the arsenical.

MILTON HANKE

Cimozyl in pulmonary tuberculosis. PAUL CANAKIS. *Boll. chim. farm.* **63**, 193-4 (1924); *Thesis, Montpellier* 1923.—Cimozyl contains 0.05 g. benzyl cinnamate and 0.1 g. cholesterol in 5 cc camphorated oil. Injections of 5 cc. daily resulted in regression of the lesions, decrease of fever, increase of red and white cell count. The bacteria of the sputum showed agglutination and degeneration. C. attributes this effect not to bacteriolysis proper, but to destruction of the bacterial membrane by cell diastases, the production of which is stimulated by Cimozyl. The response of infantile tuberculosis is particularly good, probably because of the restoration by cholesterol of the lipoids of the attacked ganglia.

MARY JACOBSEN

Pharmacological study of the oil of knee pine. AJAZZI MANCINI. *Boll. chim. farm.* **64**, 449-59(1925).—The oil of *Pinus mughus* and *Pinus pumilio* has no irritating action in direct contact with mucous membranes. When inhaled or subcutaneously injected it produces in frogs and white mice after a short excitation period depression ending in paralysis and death. Rabbits tolerate daily oral doses of 0.3-1 g. per kg for several weeks without any renal lesions. Almost the entire oil is eliminated in the urine as a glucuronate. The germicidal power tested by the methods of Chamberland and Cadeac-Meunier on *B. subtilis*, *Staph. aureus* and *albus*, Shiga-Kruse and pneumococci was found to be negligible.

MARY JACOBSEN

Is antimony an antimalarial remedy? H. SMITS. *Geneeskundig Tijdschr. Nederland. Indie* **65**, 518-20(1925); cf. *C. A.* **16**, 3129 and Tewfik-Salim, *Arch. Schiffs. Tropenhyg.* **29**, 183-6(1925).—Stibenyol, Stibosan and Heyden 661 with 33, 30.5, and 12.5% Sb proved to be ineffective in a no. of malaria cases, all of which yielded promptly to quinine. Unlike tartar emetic they had no untoward effects and are therefore recommended for all cases, which in addition to malaria need Sb treatment.

M. J.

Sodium bromide in dermatology. F. L. SCHEEPE. *Geneeskundig Tijdschr. Nederland. Indie* **65**, 521-4(1925); cf. Lebedjew, *Dermatol. Wochschr.* **76**, 1003.—Ten % NaBr given intravenously is harmless and a powerful agent in all itching dermatoses. Acute eczemas and dermatitides usually yield to a few injections without local treatment. Chronic eczemas and other itching dermatoses (lichen ruber, psoriasis vulgaris, scabies, parasitic eczema) are always favorably influenced, probably because of the rapid disappearance of pruritus and secondary scratch infections.

MARY JACOBSEN

The biochemistry of alkaline earths. ERNST HODEL. *Helvetica chim. acta* **8**, 514-8(1925).—Strongly diuretic solns. contg. 0.2 mol. CaCl_2 and SrCl_2 each, 10.0 g. NaCl and 1.0 g. KCl in 1000 cc. were injected into the jugular vein of rabbits in order to find whether Ca can be replaced by Sr in the body. In the blood Ca was far in excess of Sr, the larger part of the latter being excreted in the urine. A Sr depot was found in the skin, while Ca was retained in the kidneys. In the spleen only Ca was

found. The liver contained both ions in equiv. amts. The expts. show the tendency toward a rapid elimination of the foreign ion. MARY JACOBSEN

Changing opinions regarding pancreas therapy. H. R. HARROWER. *Am. Med.* **31**, 127-31(1925).—A discussion showing that insulin is not entirely destroyed by digestion; insulin does not represent the entire pancreas value; oral pancreas therapy is of value in supplementing insulin in certain cases. FRANCES KRASNOW

Intravenous application of radium. E. E. FIELD. *Am. Med.* **31**, 435-7(1925).—Injection of RaCl_2 (absolutely free from BaSO_4) is beneficial in the treatment of high blood pressure, apoplexy and senile decay. FRANCES KRASNOW

Chemotherapy of antimonial compounds in kala-azar infection. XVI. Observations on blood cultures of kala-azar patients on NNN medium during 1922-24. 1. Comparative value of peripheral blood culture, spleen blood culture and spleen puncture in the diagnosis of kala-azar. 2. The period at which sterilization of the peripheral blood takes place during treatment with urea stibamine. U. N. BRAHMACHARI AND B. B. MAITY. *Indian J. Med. Research* **13**, 21-4(1925).—Ninety seven % of the cases (140) showed positive peripheral blood culture. 81.5% of the spleen blood culture cases (220) showed positive culture. The period for sterilization due to urea stibamine treatment varied. 9 cases were sterilized in 4 days, 3 in 6 days, 15 in 10 days, 7 in 16 days and 3 required more than 16 days. FRANCES KRASNOW

Cephalandra indica (Telakucha) in diabetes. R. N. CHOPRA AND J. P. BOSE. *Indian J. Med. Research* **13**, 11-6(1925).—Contrary to current opinion, the fresh juice from the leaves of *Cephalandra indica* produces no marked reduction in the sugar of the blood or urine. FRANCES KRASNOW

Studies in iodine-feeding. II. The effect of iodine as potassium iodide when administered in varying amounts to pregnant ewes. J. M. EYVARD, A. R. LAMB AND W. G. GAESSLER. *J. Am. Vet. Med. Assoc.* **67**, 746-55(1925).—The optimum I content of rations is unknown. Doses of 2-6 g. KI showed marked unfavorable effects while $\frac{1}{2}$ to 1 g. prevented goiter. Cf. *C. A.* **19**, 3299. FRANCES KRASNOW

Experiments in metallurgical poisoning of animals at Oroya, Peru, at an elevation of 12,200 feet. J. F. MITCHELL. *J. Am. Vet. Med. Assoc.* **68**, 330-5(1925).—Tolerance of cattle and sheep for As, Pb oxide and flue dust is a matter of general health, rather than of elevation. Healthy animals took large doses before developing symptoms while a sick one died promptly. Sheep are not so much affected as cattle. Sheep in good health withstand and get fat on 4.285 g. As, 25.443 g. Pb oxide or 13.098 g. flue dust. FRANCES KRASNOW

Male fern—its toxicology and its use in liver rot. R. F. MONTGOMERIE. *J. Comp. Path. Therap.* **38**, 1-26(1925).—The administration of male fern ext. in amounts much less than that which may prove lethal to Welsh Mountain ewes destroys all the flukes present in the larger bile ducts. "Damstole" is not more efficient. Neither prep'n will destroy immature flukes present in the parenchyma of the liver or very small bile ducts. FRANCES KRASNOW

Treatment of camels affected with *Trypanosoma soudanense* with "Bayer 205" and further observations on the formol-gel test. R. H. KNOWLES. *J. Comp. Path. Therap.* **38**, 42-6(1925).—"Bayer 205" seems valuable in the treatment of trypanosomiasis in camels. One dose of 10 g. has proved efficient. The reaction to the formol-gel test disappears gradually after the treatment. FRANCES KRASNOW

The physiological and chemical studies of the Tanret guanidine base, galegine. HELMUT MÜLLER. *Z. Biol.* **83**, 239-64(1925).—Galegine is isolated as the picrate, $\text{C}_6\text{H}_5\text{N}_3 \cdot \text{C}_6\text{H}_5\text{N}_3\text{O}_7$, m. 178° and the chloroaurate of dihydrogalegine, $\text{C}_6\text{H}_5\text{N}_3 \cdot \text{HAuCl}_4$, m. 147°. Galegine is contained in *Galega officinalis* and in the leaves of the "geiss-klee". Yeast does not act on galegine. During putrefaction it is changed to optically inactive oxydihydrogalegine. Subcutaneous administration of galegine causes death 6 to 8 days with symptoms similar to those obtained when the plant is fed. It is excreted in the urine. Three new cryst. compds. of galegine were isolated. The quantities recovered were too small for identification. FRANCES KRASNOW

Investigation of the respiratory quotient after alcohol intake during work. H. J. BRECHMANN. *Z. Biol.* **83**, 325-48(1925).—Upon the administration of 30 g. alc., there was obtained a marked depression of the respiratory quotient when the subject was burning mainly carbohydrate. FRANCES KRASNOW

Clinical and experimental studies on sodium benzoate. A. W. BRYAN. *J. Clin. Invest.* **2**, 1-33(1925).—2.4 g. BzONa (equiv. to 2.0 g. BzOH) was given by mouth to patients and normal persons. In the latter 70% or more of the BzOH equiv. was excreted as hippuric acid in the urine in 2 hrs., 85-90% or more in 3 hrs. In nephritis the excretion was considerably reduced, even in early cases when the blood urea was

normal. In nephrosis normal values were found. Hepatic disease in man or exptl. lesions in dogs affects the results only insofar as sufficient glycocoll may not be available for the synthesis. Excretion of free BzOH above 3% of the administered dose of BzONA suggests secondary hepatic lesion.

LOUIS LEITER

The present status of chlorine gas therapy. H. B. VEDDER. *Ann. Clin. Med.* **4**, 21-9(1925).—The optimum concn. is 0.015 mg. per l. The best length of exposure is 1 hr. It can be used for simple respiratory infections, for whooping cough, and in the early stages of influenza.

JOHN T. MYERS

Physiological action of (alcoholic) aromatic solutions. A. DOULY AND R. M. GATTEFOSSÉ. *Chimie et industrie Special No.*, 392-6(Sept. 1925); cf. *C. A.* **18**, 1712.—Previous results obtained on the non-toxicity and therapeutic effects of pure volatile compds. and terpeneless essential oils have been extended to their EtOH solns. Guinea pigs that were given large doses of 30% alc. (0.5 g. for 8 days, 1 g. for 5 days, 1.5 g. for 10 days, 2 g. for 5 days, 2 days rest, and a final lethal dose of 6-7 g.) showed all the signs of alcoholism after the 3rd day, while animals having received the same doses of alc. contg. anethole, tincture of fennel and terpeneless lemon oil, resp., remained in good health to the end, and postmortem examn. showed no abnormal conditions.

A. PAPINEAU-COUTURE

The role of surface tension in the increase of anesthesia by alkalinization of solutions of cocaine hydrochloride. JEAN RÉGNIER AND ROBERT DAVID. *Bull. sci. pharmacol.* **32**, 513-23(1925); cf. *C. A.* **19**, 3000.—Contrary to the conclusions of other investigators, the addn. of alkali to fresh solns. of cocaine increases the anesthetic power neither by setting free a more powerful anesthetic nor by a diminution of the surface tension. The increased anesthetic power is due to the action of the alkali on the receiving cell.

L. W. RIGGS

Pancreatic extract of *Acanthias vulgaris*; its action compared to that of insulin from beef pancreas. E. DUCLOUX AND (MLE.) G. CORDIER. *Compt. rend.* **181**, 312-4(1925).—The hypoglycemic action of the subcutaneously injected pancreatic ext. of the shark (*Acanthias vulgaris*) upon the guinea pig and upon the rabbit appears (1) to bear no proportional relation between the quantity of the shark insulin injected and the wt. of the animals; (2) there is no proportional relation between the hypoglycemia and the quantity of shark insulin per same wt. of animal; (3) the lowering of the sugar is greater following intracardiac injections.

L. W. RIGGS

The fate of camphor and of the oil after experimental injection of camphorated oil. LÉON BINET AND RENE FABRE. *Compt. rend.* **181**, 441-3(1925).—The expts. were made with dogs. The camphorated oil consisted of neutral olive oil and camphor 9 to 1, to which was added 0.1 g. of diphenylanthracene to 1000 g. to render the soln. fluorescent. The camphorated oil was injected aseptically either subcutaneously or intramuscularly in doses of 20 g. After injection the animals were placed in a cage for urine collection and were killed 2, 3, 5, 7, 9, 19, 24, or 48 hrs. after the injection, when the camphor in the urine and tissues and the oil in the tissues were detd. The camphor is rapidly eliminated from the tissues by the renal route, while the oil remains at the site of the injection for some weeks and is absorbed by means of an afflux of leucocytes which surround the oily droplets—a veritable encystment.

L. W. RIGGS

Diuretic action of ammonium chloride and novasurol in cases of nephritis with edema. N. M. KEITH, C. W. BARRIER AND MARY WHELAN. *J. Am. Med. Assoc.* **85**, 799-806(1925).—A group of patients selected on account of their inability to excrete salts and water was treated with controlled diets, NH_4Cl and novasurol. The combined action of these 3 factors produced beneficial effects when each singly was ineffective. These results have not been obtained previously. Diuresis, in cases of edema, is associated with increased excretion of Na whether it occurs spontaneously or following the exhibition of NH_4Cl or novasurol.

L. W. RIGGS

Basis for the physiological activity of certain onium compounds. R. RENSCHAW. *Science* **62**, 384-9(1925).—A cooperative research is underway among the workers in different labs., to study the physiol. activity of onium compds. on the nervous system. The process of action is complex and does not appear to be due to their chem. decomposition, their activity as bases, nor to their distribution coeffs. The mobility of their ions is not of primary significance. To be physiologically active these substances must exist in the body fluids as cations. Various probabilities to account for their action are proposed. Several papers on the subject will appear shortly.

L. W. RIGGS

Significance of hexylresorcinol and its homologs in relation to the problem of internal antiseptics. VEADER LEONARD. *Science* **62**, 408-12(1925).—Hexylresorcinol is by far the most powerful germicide ever described as possessing anything like its degree of non-toxicity to animals and to man. It has been developed and applied as an internal

urinary antiseptic by a logical and orderly application of the chem. and biol. characteristics of its lower homologs, and exemplifies a method by which sp. problems in internal antiseptics may be gradually narrowed down through the enhancement of desirable biol. properties definitely attributable to chem. constitution. L. W. RIGGS

The cardiovascular and diuretic action of calcium salts. L. BRULL. *Arch. intern. med. exp.* 1, 613-47(1925).—See C. A. 19, 132. FLORENCE SEIBERT

Testing purgatives in the white mouse. S. LOEWE AND GERTRUD FAURE. *Arch. expl. Path. Pharmacol.* 107, 271-86(1925).—The passage of food through the intestine of the white mouse can be followed by administering India ink by stomach tube and by detg. the distance to which the pigmented material has advanced after different intervals of time. Material passes through the intestinal tract of the mouse very rapidly; within 1 hr. after the stomach is filled the process begins and within a further half hour the food has traversed half of the length of the intestine. The effect of purgatives in modifying the speed of the transfer can readily be detd., and of the substances tested it appears that senna and colocynth were very good, $MgSO_4$ and castor oil were good, and $HgCl_2$ was very uncertain in its action. G. H. S.

Mode of action and point of attack of procaine on the small intestine. FRITZ SCHNELLER. *Arch. expl. Path. Pharmacol.* 108, 78-95(1925).—Apparently procaine has its primary action upon the "receptive substance" of the intestinal musculature. Reduction in the physiol. tonus is clearly evidenced by the prompt loss in motility. Upon the small intestine treated with choline or physostigmine the action of novocaine is unchanged although contraction to Ba in the usual dosage is not abolished. The procaine-treated intestine requires large doses of choline and physostigmine to induce the usual stimulation; $BaCl_2$ is active in the normal amts. G. H. S.

Blood picture in those who work with hydrocyanic acid. C. M. HASSELMANN. *Arch. expl. Path. Pharmacol.* 108, 106-20(1925).—Study of the blood of about 100 persons who had worked with HCN for a greater or less length of time showed that the hemoglobin content was usually high, the no. of red cells were somewhat increased although normal in morphology and staining properties, the white cells were not materially changed although there was a slight lymphocytosis and the basophils were slightly above normal. Monocytes were frequently increased. Blood pressure was within normal limits. G. H. S.

Possibility of experimentally altering the physiological secretory equilibrium between the pancreas and the adrenals by irradiation and the effects upon the vegetative nervous system. I. Irradiation miosis and mydriasis. OTTO RISSE AND FRITZ POOS. *Arch. expl. Path. Pharmacol.* 108, 121-48(1925).—By suitable irradiation procedure pharmacol. highly active substances appear in the circulation in amts. which cause both a mydriasis and a miosis with the denervated and the maximally atropinized pupil. The mydriatic substance is probably adrenaline. The miosis is of peripheral origin and is probably due to some substance of hormonal derivation, whose chief characteristic is to remove atropine paralysis of the pupil. The pancreas must be considered in connection with its possible source. G. H. S.

Physiology and pharmacology of irritability of the frog heart. I. The isolated ventricle. KARL JUNKMANN. *Arch. expl. Path. Pharmacol.* 108, 149-206(1925).—The rhythmic changes in irritability of the frog heart comprise an abs. refractory phase, a relatively refractory phase, a period of abs. irritability, and a period of diminishing irritability. Corresponding to these changes in irritability are changes in contractility. Substances of the narcotic group, EtOH, Et₂O, $CHCl_3$, urethan, veronal, and paraldehyde, in suitable concns. shorten the refractory phase without altering contractility. Substances of the digitalis group, digitalis, scilla, oleander glucoside, cymarine, and strophanthin, widen the contraction curve with a simultaneous slight lengthening of the abs. refractory phase and an ultimate shortening of the refractory phase with increase in irritability. $BaCl_2$ greatly extends the contraction curve and lengthens the latent period. Abs. irritability and general contractility are both modified. $CaCl_2$, like digitalis, shortens the refractory phase. $SrCl_2$ does not alter either irritability or contractility. Of the alkaloids, quinine, quinidine, and atropine show their greatest effect—a reduced irritability—only after a considerable period. Caffeine and adrenaline broaden the contraction curve. With caffeine the abs. refractory phase is lengthened, the abs. irritability is somewhat reduced. Adrenaline increases the abs. irritability somewhat. With physostigmine the increase in irritability in the relatively refractory phase is delayed. Morphine and strychnine shorten the refractory phase and have a variable effect upon contraction. The latent period may be greatly lengthened; with high concns. the effects resemble that of quinine. Acetylcholine shortens the refractory phase; irritability is unchanged or diminished; and contractility is

considerably reduced. The ethereal oils cause a more or less outspoken reduction in contraction and an abs. and relative shortening of the abs. refractory phase. Irritability is reduced. Camphor causes a primary shortening of the refractory phase and of contraction and irritability is diminished. II. *Ibid* 313-52. —Ether causes a marked retardation of rate; the abs. refractory phase is somewhat shortened, but the development of irritability and the abs. irritability are hardly changed. Stimulus conduction is favored. CHCl_3 greatly retards the rate, while irritability and cond. are not materially changed although the latent period is lengthened. Chloral hydrate causes a marked slowing of rate; the abs. refractory phase is prolonged and irritability is somewhat reduced. BaCl_2 markedly retards frequency; the abs. refractory phase is lengthened; irritability is changed but little; stimulus conduction is diminished; and the latent period is prolonged. Digitalis and strophanthin modify frequency but little, nor is irritability greatly changed. Only in the toxic stage is conduction modified. Quinine slows the rate and lengthens the abs. refractory phase both as to irritability and conduction. It also lengthens the latent period. Quinidine, atropine, physostigmine, and morphine have similar effects, as, in many respects, has camphor also. G. H. S.

Phases of action of digitalis on the isolated heart. L. GARCAWY-LANDAU. *Arch. expl. Path. Pharmacol.* 108, 207-19 (1925).—The true action of a poison on an isolated organ can only be ascertained by considering all phases of its action. From a consideration of all of the phases of action it appears that the isolated heart of *Bufo vulgaris* is as sensitive to digitalis as is that of *Rana esculenta*, presenting the same characteristic changes in activity. With a dose that is quickly toxic, the curve of action is characterized by a rapid initial fall in activity and a max. heart contraction at the beginning of the recovery phase. The increased activity of the phase of recovery is considerable and may be intensified very markedly by various agencies, e. g., by repeated preliminary treatment with alc. The effects of digitalis on contraction height are not lost by repeated treatments with the drug. During protracted exposure to digitalis the period of heart inactivity is interrupted by single or group contractions of the same character as those which appear when activity is restored by washing. The amplitude of the max. contractions does not depend upon the height of the contractions prior to the digitalis treatment, but is rather a const. The peculiarities of the successive phases of action of digitalis may be interpreted as an expression of a stimulation of heart muscle and an inhibition in the production and conduction of stimuli. G. H. S.

Comparative digitalis evaluation in frogs and cats. T. KURODA. *Arch. expl. Path. Pharmacol.* 108, 230-7 (1925).—In testing several preps. in both frogs and cats the variability in the results obtained in frogs was somewhat greater than that in the results obtained with cats. G. H. S.

Pharmacological study of the action of intracutaneous stimulation. I. FRIEDRICH LUTHLEN and HANS MOLITOR. *Arch. expl. Path. Pharmacol.* 108, 248-54 (1925).—The intracutaneous injection of non-irritating solns. (0.9% NaCl) in the absence of pain (deeply narcotized animals) considerably increases the irritability of the vagus to faradic stimulation. The same action is manifest in other tissues whose nerve endings have a relationship similar to those of the outer layers of the skin, e. g., the conjunctiva and the cornea. G. H. S.

Action of adrenaline, hypophysis extract and histamine on the blood stream of the small vessels of the frog tongue. HANS KILLIAN. *Arch. expl. Path. Pharmacol.* 108, 255-79 (1925).—Upon the entire arterial bed of the tongue of the frog adrenaline causes a sp. active contraction. The nature of the effect depends upon the differing degrees of susceptibility of the different sections of the bed rather than upon the natural direction of flow. The degrees of susceptibility appear to be directly dependent upon the anatomical strength of the walls of the vessels and the arrangement of their muscular elements. The regions of the valves of the arterioles and the arterial capillaries are the most susceptible, reacting first and to the smallest doses. This peculiar susceptibility of the valve is not, however, sp. for adrenaline. The local action of adrenaline is manifest in a diln. of 1 to 1 million. Hypophysis ext. actively contracts the arterial bed. As with adrenaline, the venous bed is modified only secondarily. Here again the first effects are observed in the valve regions; in fact the difference on the vessels as compared with adrenaline is a matter of degree, hypophysis ext. being less active. The vascular reaction of hypophysis exts. parallels the melanophore reaction; adrenaline never causes the latter. Histamine acts as a general vaso-dilator, acting upon the entire arterial system, and at times upon the venous capillary bed. G. H. S.

Methemoglobin restitution. VI. Ferricyanide and quinone at different reactions. ROLF MEIER. *Arch. expl. Path. Pharmacol.* 108, 280-94 (1925).—Ferricyanide reacts

with oxyhemoglobin at p_H 5.7 almost the same as at 9.2. At p_H 5 and in a molar relationship of 1, about 98% as much O is liberated as by a satd. ferricyanide soln. At p_H 7, the corresponding percentage is 95%. In an alk. reaction about 90% is liberated. With a molar relationship of 2 in a neutral reaction a max. O liberation is obtained; while in an alk. reaction there is slightly less than a max. liberation. Quinone reacts in acid reactions about as intensively as ferricyanide. With a 2-fold molar excess the max. O liberation is attained. At a neutral reaction it requires a 10-fold excess to liberate 90% of the available O. In alk. reactions the quinone itself is oxidized. G. H. S.

Intravenous silver therapy. III. Solubility of silver salts in the blood and body fluids with reference to silver-protein combinations. K. v. NEERGAARD. *Arch. expl. Path. Pharmacol.* **108**, 295-312 (1925); cf. *C. A.* **20**, 71.—The degree to which Ag ions can occur in the blood after the introduction of dissociated Ag compds. is detd. primarily by the concn. of Cl ions and corresponds to approx. $1 \cdot 10^{-9}$. The max. concn. of Ag to be attained in the tissues is, therefore, a function of the Cl content. When dissociated Ag is added, the Ag-ion concn. in the blood increases far more slowly than in an isonic electrolyte soln., and it requires a some 500-fold amt. to attain the max. concn., so that an amt. of about 750 mg. per l. is necessary to attain this end. The component of the blood which causes it to differ so greatly from a pure electrolyte soln. is the albumin, apparently the globulin is inert. The formation of compds. with Cl and with albumin occur simultaneously, and there is an equil. between the 2 reactions.

• **IV. The silver-ion concentration in the process of disinfection in physiological media.** *Ibid.* 143-63.—The concns. of $AgNO_3$ in distd. water and in bouillon necessary for growth inhibition and for germicidal action are. In distd. water a Ag ion concn. of 0.12×10^{-6} , $N = 0.13$ mg./l. is inhibitory and is much greater than that required to give the same effect in bouillon ($1.8 \times 10^{-9}/N = 0.00019$ mg./l.). The discrepancy between the concn. of Ag ions necessary for bactericidal action in distd. water and that in a physiol. medium is explained by the fact that in the latter, together with the ionized Ag, complex Na Ag chlorides are formed and these also exert a disinfecting action. Detns. of the Ag-ion concn. show that in water, bouillon and in serum the union of Ag with bacteria is an adsorption process.

V. Does an unknown physical force—oligodynamic action of Saxl—play a role in intravenous silver therapy? *Ibid.* 164-77.—There is no evidence that an unknown phys. force is operative. G. H. S.

Digitalis and the "peripheral" heart: A new method of blood pressure analysis. A. N. SCHESTAKOFF. *Arch. expl. Path. Pharmacol.* **108**, 353-64 (1925).—With the circulation in the arterial systems in equil. the amt. of blood flow per min. = $M = 2h_m xy$, where h_m is the av. pressure and xy the sum of the systolic phases in 1 min. According to Garrad's formula $xy = 20\sqrt{n}$, where n = the pulsations per min. From this may be derived the sec. vol., $S = 2h_m xy/60$; the beat vol., $N = 2h_m xy/n$; the amplitude vol., $Q = 2h_m(xy-n)/n$; the av. cross section of the arterial reservoir $\pi x^2 = 2h_m(xy-n)/An$, where A = the pulse amplitude; the tonus of the vessels $a = An/xy-n$; and the extent of the arterial reservoir, $V = \pi x^2 h$. Primarily digitalis acts directly on the central heart, so that its energy is increased and the blood output per beat is augmented, with a resultant change in equil. within the system. This change is reflected in a reflex effect of the vasomotor system, regulating the pulse and the tonus of the vessels. This adjustment takes place very quickly, but can be accomplished only if the conduction capacity of the vasomotor system and the vessels is normal. G. H. S.

Intestinal peristalsis. II. Peristaltic processes during the action of saline purgatives. MAX BAUER. *Arch. expl. Path. Pharmacol.* **109**, 22-34 (1925).—With salt concns. of 2 to 4% the inhibition of peristalsis, following the primary stimulation, is but temporary and is relatively slight. With greater concns. of salts (10 to 20%) in large doses without an adequate amt. of fluid the transportation of the intestinal contents is not stimulated. Furthermore, the higher the concn. of salt the longer is the period of inhibition.

III. Effect of oils, colocynth, gamboge and calomel on the peristaltic process. *Ibid.* 233-48.—With the isolated guinea pig intestine differences in the action of castor oil, croton oil, colocynth, gamboge and calomel can be observed comparable to those noted in the intact animal. Castor oil and croton oil cause, at times, an increased peristalsis with an accelerated transportation of material. With croton oil irritating effects are often so strong that they lead to a closure of the intestinal lumen and to an arrest of the peristalsis. Colocynth has a strong stimulating effect on the intestinal musculature; in active concns. the peristalsis is often augmented, with a disturbance in the physiol. regularity. Small quantities of gamboge stimulate physiol. peristalsis, with an abnormally rapid progression of the waves, but with higher concns., as with colocynth, physiol. regularity is destroyed. Calomel strengthens peristalsis

and transfer of material, the peristaltic waves being intense with the physiol. regularity undisturbed.

Evaluation of glucosides active on the heart by oral administration to frogs. L. LENDLE. *Arch. expl. Path. Pharmacol.* **109**, 35-49(1925).—When administered by mouth to frogs strophanthin and digitalein are much less active than when given subcutaneously while with digitoxin, verodigen, and possibly with scillitoxin also, the lethal doses are essentially the same whether given by mouth or by injection. Convallamarin stands midway between the 2 groups, the lethal dose by mouth being 13.2 times greater than the subcutaneous dose. When given *per os*, essentially the same activity is shown by digitalis in either the powder or in the infusion form. Curarized frogs are as susceptible as are normal frogs to lethal doses of digitalis.

Experimental study of the action of the local anesthetics psicaine and tutocaine. WILHELM WAGNER. *Arch. expl. Path. Pharmacol.* **109**, 64-73(1925).—Tested by the infiltration method in man or by the method of surface anesthesia on the rabbit cornea psicaine is effective in approx. the same concn. as is cocaine. Tutocaine, on the contrary, is only about a fourth as active as cocaine. The minimal lethal dose of tutocaine is 4 times as great as that of cocaine; that of psicaine is twice as great. Psicaine causes a relatively marked irritation and hyperemia of the tissues, reactions which are lacking with tutocaine. When combined with adrenaline the anesthesia is prolonged, although the concn. of anesthetic cannot be diminished. The addn. of K_2SO_4 intensifies the action of both preps. in infiltration anesthesia. For surface anesthesia the action is strengthened by the addn. of phenol. Solns. of the preps. deteriorate rather quickly (1-2 days) on standing. With the isolated frog heart both preps. behave like cocaine.

Comparison of the narcotizing and toxic effects of some halogen hydrocarbons. JOHANNES MÜLLER. *Arch. expl. Path. Pharmacol.* **109**, 276-94(1925).—The narcotizing effects for white mice of $CHCl_3$, methylene chloride, tetrachloromethane, tetrachloroethane, dichloroethylene, ethylidene chloride, ethylene chloride, Pr chloride, EtBr and Pr bromide were tested, their relative values being detd. by comparison with $CHCl_3$. This last, used in a concn. of 0.027 g. per l., gave a deep narcosis after some 30 min. and was ultimately fatal after an exposure of 1.5 to 2 hrs., necropsy showing fatty infiltration of the liver with degenerative changes. Methylene chloride was about 3.5 times less active than $CHCl_3$. Tetrachloromethane was 1.5 times less active as a narcotic and was somewhat more toxic than $CHCl_3$. Tetrachloroethane had the highest narcotizing action of all of the compds. tested, being 3.5 times stronger than $CHCl_3$. In narcotic action dichloroethylene is to $CHCl_3$ as 1.5 is to 1. Fatal after-effects did not appear with ordinary doses but pronounced changes in the organs followed exposure to high concns. Ethylidene chloride was only $1/2$ as active as $CHCl_3$ and fatal after-effects did not appear. EtCl was fatal in doses which had no narcotizing effect. The least active compd. as a narcotic was Pr chloride, being $1/7$ as active as $CHCl_3$. Its toxicity was slight. EtBr bromide was $1/4$ as active as $CHCl_3$; Pr bromide $1/3$ as active. The latter was toxic in narcotizing concns. Thus, as regards narcotic effect the series stands: Pr chloride, EtBr, methylene chloride, ethylidene chloride, Pr bromide, dichloroethylene, tetrachloromethane, ethylene chloride, $CHCl_3$ and tetrachloroethane. Arranged according to increasing toxicity: Pr chloride, dichloroethylene, ethylidene chloride, methylene chloride, Pr bromide, ethylene chloride, EtBr, $CHCl_3$, tetrachloromethane and tetrachloroethane.

Pharmacological estimation of atropine and scopolamine solutions and their stability. GUSTAV KÜHL. *Arch. expl. Path. Pharmacol.* **109**, 295-9(1925).—Minute quantities of atropine and of scopolamine can be detected by means of blood pressure detns. in cats. The salts of both compds. undergo no loss in acid and alk. reactions (up to pH 9.2) and in heating at 100° for 30 min. They are relatively resistant to alkali.

Absorption, excretion, and distribution of small quantities of lead. BEHREND BEHRENS. *Arch. expl. Path. Pharmacol.* **109**, 332-57(1925).—Administered by mouth Pb (as chloride) is absorbed very slowly, the max. concn. being reached only after 10 hrs. With the administration of small quantities the degree of absorption is proportional to the amt. ingested, but with larger doses the proportion absorbed is diminished. Excretion is chiefly through the feces; the urine contains but little, the expired air none. The extent of the excretion is to a degree proportionate to the concn. of Pb in the body, being relatively high during the first 24 hrs. and then diminishing. After oral, like after intravenous administration, Pb appears particularly in the liver, kidney, bone and intestine. Skin, brain, fatty tissues, muscle and lung are practically free from Pb.

G. H. S.

Influence of saponin upon the absorption of strophanthin and digitoxin. L. KOFLER AND R. KAUREK. *Arch. expl. Path. Pharmacol.* **109**, 362-9(1925).—When saponin is administered by mouth simultaneously with strophanthin or with digitoxin the action of the latter compds. is increased to such an extent that the amt. of strophanthin necessary to cause systolic arrest of the frog heart is reduced to $\frac{1}{3}$, of digitoxin to $\frac{1}{6}$, of the normal amt. This effect is apparently due to an increased absorption from the digestive tract. The effective intralymphatic dose of strophanthin is 0.001 mg. per g.; the *per os* dose is 0.09 mg.; but with a simultaneous administration of saponin the effective oral dose becomes 0.0027 mg. Saponin has a similar, but less pronounced, effect in mice. The lethal dose of digitoxin is reduced by saponin to $\frac{1}{4}$, that of strophanthin to $\frac{1}{2}$. The effect of saponin upon the toxicity of strophanthin for rabbits is doubtful. G. H. S.

Arsenic tolerance. E. AND J. KEESER. *Arch. expl. Path. Pharmacol.* **109**, 370-7(1925).—Although a participation of the lung in the elimination of As could not be detected, the hair of 2 dogs tolerant to As contained such large amts. of As as to make it clear that the hair and probably the entire ectoderm plays a significant role in the deposition and excretion of As. G. H. S.

Pharmacology of body position and the labyrinthine reflex. XIII. Hashish. ERNST JOEL. *Arch. ges. Physiol.* (Pflüger's) **209**, 526-36(1925).—After the administration of ext. of *Cannabis indica* by mouth dogs and cats show an intoxication picture characterized by reeling, lack of movement, a cataleptic-like condition and a general lethargy. The reflex mechanism which regulates body position is but slightly deranged. In decerebrate cats no comparable effect is observed. Apparently the peculiarities of the action of hashish are due to a predominating effect upon the cerebrum. **XIV. Action of bulbocapnine on the intact cat.** GEORG SCHALTENBRAND. *Ibid* 623-42.—In doses of 2.5-5 mg. per kg. of body wt. bulbocapnine causes a loss of movement in cats, but is without effect upon either position reflexes. Larger doses (10-25 mg.) cause a complete loss in motion with a retention of flexion, and the labyrinthine head position reflex as well as the body position reflex are abolished. Still larger doses (40 mg.) restore these reflexes and the retention of flexion becomes changed to a retention of extension. The vision reflex becomes active and muscle tonus is increased. With max. doses (70 mg. or more) tic-like movements develop, with an extreme increase in reflex irritability and the appearance of an epileptic state. Death takes place during a period of respiratory inactivity. **XV. Action of bulbocapnine on the spinal cord and decerebrate cat.** *Ibid* 643-52.—In the spinal cord of the cat small doses (0.0001-0.015 g.) diminish reflex irritability; large doses (0.03 g. or more) cause an increase in tonus, spontaneous twitchings, tremors, etc., and effects resembling those of strychnine—increased reflex, reduction in threshold, distribution of reflex action over the entire body. In decerebrate cats large doses show the same effects, but with small doses a diminution of reflex action is not observed. **XIV. Action of bulbocapnine on thalamus cats.** OTTO GRINDT AND GEORG SCHALTENBRAND. *Ibid* 653-63.—Tested on thalamus cats, small doses (0.0004 g. per kg.) given intravenously to animals with isolated leg muscles caused a marked loss or abolition of the periodic motor discharges, while the spinal cord reflexes remained unchanged. Unconfined thalamus cats did not react at all to small subcutaneous injections, but with larger doses (0.02 g.) they became quiet. The reactions characteristic of the intact animals were lacking. Larger doses (0.04 g.) caused a return of spontaneous activity with a loss of coordination. Doses of 0.1 g. caused tonic convulsions with augmented reflexes. The epileptic state did not appear. **XVII. Action of bulbocapnine on cats with damaged cortex. Localization of symptoms which develop in the intact animal during bulbocapnine intoxication.** GEORG SCHALTENBRAND. *Ibid* 664-74.—In the acute expt. bulbocapnine acts on the animal with damaged corpus striatum exactly as on the thalamus animal. Animals with a bilateral destruction of the centralis react more strongly than decerebrate animals, and less intensively than does the normal animal. Apparently bulbocapnine attacks the whole of the central nervous system, and, in general, small doses are depressing while large doses are stimulating. Cataleptic-like phenomena occur after av. doses only in animals with an intact cerebrum. G. H. S.

Role of some electrolytes on the innervation mechanism of secretory processes. I. Action of vegetative poisons on the activity and on the electrolyte content of the saliva of the submaxillary gland. DANIEL ALPERN. *Arch. ges. Physiol.* (Pflüger's) **209**, 723-37(1925).—The saliva is characterized by a const. relationship as to its content in Ca and in K salts. The relation of these salts to each other is of particular importance as regards salivary secretion, since the coeff. of the relation of Ca to K det. the character of the secretory process. Pilocarpine, and physostigmine especially, give

occasion to a salivary secretion of normal electrolyte content, while suprarenine causes an increase in the Ca content or a reduction in K. Adrenaline saliva is to be considered as a mixed secretion product, in that it is induced both by a stimulation of the sympathetic nerve endings and by stimulation of the parasympathetics. Casensiti zes to the sympathetic action of suprarenine; K appears to be antagonistic to this action. The effect of Ca is undoubtedly connected with the action of the sympathetic nerves, while K is associated with the parasympathetic innervation. II. Effect of section and of stimulation of nerves on the activity and electrolyte content of the saliva of the sub-maxillary gland. *Ibid* 738-52.—Further evidence of the close relationship of Ca and K is presented. G. H. S.

A discussion of the use of alkali in the treatment of diabetic coma. BYRON D. ROWEN AND GILBERT M. BECK. Buffalo General Hospital, *Bull.* 3, 13-7(1925).—For diabetic coma or threatened coma 20-25 g. NaHCO_3 is recommended, particularly in patients who show a retention of org. acids or where a degree of nephritis is present. NATHAN VAN PATTEN

Effect of ethyl urethan anesthesia on the acid-base equilibrium and cell contents of the blood. J. A. HAWKINS AND J. B. MURPHY. *J. Exptl. Med.* 42, 609-18(1925).—When anesthesia is produced in rabbits or rats by injections of Et urethan, the CO_2 content and p_{H} of the whole blood of the animal are more or less rapidly increased to a point where there is a marked uncompensated alkalosis which reaches its max at 24 hrs. and persists for 48 hrs. The increase in the CO_2 content and p_{H} of the whole blood is accompanied by a decrease in the circulating lymphocytes and an increase in the polymorphonuclear leucocytes. C. J. WEST

Proposed standardized method for the therapeutic study of compounds in experimental rabbit syphilis. G. E. WAKERLIN, W. F. LORENZ AND A. S. LOEVENHART. *J. Pharmacol.* 26, 187-97(1925).—See *C. A.* 19, 3128. C. J. WEST

Effect of strophanthin on pulsation rate in the dorsal blood vessel of *Lumbricus terrestris*. C. L. WIBLE. *J. Pharmacol.* 26, 199-201(1925).—Strophanthin exerts its characteristic action on an elementary heart, in this case, the dorsal blood vessel of the earthworm. C. J. WEST

Pharmacology of the isolated vein ring. K. J. FRANKLIN. *J. Pharmacol.* 26, 215-25(1925).—Contraction of the isolated vein ring is caused by adrenaline, EtOH, Ba, Ca, K, large amts. of chloral hydrate, digitalin, ergamine, ergotoxin, Et₂O in some cases, nicotine, pituitrin and strophanthin. Relaxation is caused by adrenaline after ergotoxin, small quantities of chloral hydrate, Et₂O in some cases, nitrite, CO_2 and urethan. No effect is caused by atropine, acetylcholine, pilocarpine, apocodeine, caffeine, theobromine, diuretin, cocaine, Mg, quinidine and strychnine. Rhythmical movements have been observed in veins before the application of any drug and also under the influence of adrenaline, ergamine and ergotoxin. C. J. WEST

Action of urethan on involuntary muscle. K. J. FRANKLIN. *J. Pharmacol.* 26, 227-32(1925).—Urethan in doses between 1.45 and 1.200 causes diminution in tone and in rhythmic movements in involuntary muscle, as studied in isolated tissue preps. In the rabbit it affects the mesenteric vein, intrapulmonary bronchus, pulmonary artery, inferior vena cava, uterus, spleen and small intestine. In the ox it relaxes the mesenteric vein. It has no effect on the systemic aorta or gall bladder of the rabbit. It relaxes the mesenteric artery and intrapulmonary bronchus in the sheep. The action of drugs which normally cause contraction of some of the muscular tissue used is lessened or abolished. C. J. WEST

Relationship between chemical structure and physiological action. The effect of *l*-suprarenine (synthetic epinephrine) and various derivatives upon the blood sugar of normal rabbits. H. E. DUBIN, H. B. CORBITT AND LOUIS FREEDMAN. *J. Pharmacol.* 26, 233-41(1925).—The hyperglucemic action of the compds. studied is in the following order of decreasing intensity: *l*-suprarenine, *dl*-suprarenine, *dl*-Me ether of suprarenine, *d*-suprarenine, epinine, *dl*-Et ether of suprarenine, methylaminoacetopyrocatechol, suprarenine anhydride, tyramine and pyrocatechol. The importance of the sec. HO group in the configuration of the mol. is shown. Whether its orientation is such that the *d*- or the *l*-form results, is also of importance. When substitution occurs or H_2O is split out to form the anhydride, the effect on the animal organism is altered as indicated by the decreased hyperglucemic action. C. J. WEST

Influence of the adrenals on the toxicity of morphine. J. M. ROGOFF AND JOS. DE NECKER. *J. Pharmacol.* 26, 243-58(1925).—There is no foundation for the statement that double adrenalectomy in rats causes them to become 50-500 times more sensitive to morphine than normal animals. There is, indeed, no evidence that any significant change in tolerance occurs. Most of the deaths, resulting from double

adrenalectomy in rats, occur within a period of about 10 days, beginning toward the end of the 1st week following the operation. Tests for tolerance of depressing drugs or potent bacterial toxins cannot yield reliable results if made during this period of high mortality in adrenalectomized rats. C. J. WEST

Acute cocaine poisoning, its prophylaxis and treatment in laboratory animals. A. L. TARUM, A. J. ATKINSON AND K. H. COLLINS. *J. Pharmacol.* **26**, 325-35(1925); cf. *C. A.* **19**, 1907.—The av. min. fatal subcutaneous dose of cocaine is 100 mg. per kg. body wt. in the rabbit and 26.7 mg. per kg. in the dog. Artificial respiration alone is sufficient to raise the min. fatal dose in the rabbit from 100 to approx. 350 mg. per kg. In the dog and cat artificial respiration does not significantly change the min. fatal dose. The prophylactic administration of barbital Na and paraldehyde to the dog produces a condition in which the fatal dosage of cocaine lies above 100 mg. per kg., approx. a 4-fold increase in tolerance. Convulsions are completely and practically instantaneously controlled by an intravenous injection of this mixt. Likelihood of recovery from acute intoxication by cocaine in the dog is roughly inversely proportional to the time convulsions are permitted to continue. Cocaine poisoning is believed to be due to the effects of direct medullary injury together with the deleterious indirect effects of the cocaine-poisoned brain on the medullary centers. C. J. WEST

Active principles of the pituitary extract. H. H. KNAUS. *J. Pharmacol.* **26**, 337-46(1925).—Ext. equal to 1 mg. of moist posterior lobe of the pituitary injected intravenously produces in the pithed cat a strong action on the uterus lasting for at least 1 hr. together with a marked rise of blood pressure. The corresponding dose for a human being is an ext. equal to about 25 mg. of the moist gland and this appears to be the max. dose that should be given intravenously. Larger doses are permissible for hypodermic or intramuscular injection, especially as the absorptive capacity of the subcutaneous tissues is impaired during pregnancy. C. J. WEST

Action of certain drugs and ions on the rat uterus. H. H. KNAUS AND A. J. CLARK. *J. Pharmacol.* **26**, 347-58(1925).—Adrenaline causes inhibition of the rat uterus *in situ* as well as when isolated but the concn. required to produce an effect *in situ* is 10-100 times that which acts on the isolated uterus. The uterus in a late stage of pregnancy is inhibited as readily as the virgin uterus. The min. dose per kg. body wt. of adrenaline which inhibits the rat uterus *in situ* is about 0.0005 mg., which is similar to the amt. required to produce a visible rise of blood pressure in larger animals. Pituitary ext. and K excess cause similar effects, which are the opposite of those produced by adrenaline. The dose of fresh posterior pituitary lobe needed to produce a demonstrable effect on the uterus *in situ* is about 0.16 mg. per kg. body wt., this is much greater than the amt. needed to stimulate the cat uterus and the dose per rat is as high as $\frac{1}{60}$ of the active principle in a rat pituitary. Variations in the Ca content of Locke fluid do not produce in the isolated uterus of the rat effects the opposite of those produced by similar variations in the K content. C. J. WEST

Comparative study of hypnotics of the barbituric acid series. CARL NIELSEN, J. A. HIGGINS AND H. C. SPRUTH. *J. Pharmacol.* **26**, 371-83(1925).—The following figures give the min. fatal dose in mg. per g. of rat, the min. effective dose in mg. per g. of rat and the safety margin (difference between the 2 values expressed in % of the min. fatal dose) for 16 derivs. of barbituric acid: Di Et (barbital) 0.31, 0.225, 27, iso-PrEt, 0.11, 0.09, 18; BuEt (neonal), 0.19, 0.0625, 67; iso-AmEt (amytal), 0.11, 0.0575, 59; PhEt (luminal), 0.14, 0.11, 21; (PhCH₂)Et, produced convulsions, iso-PrBu, 0.16, 0.0725, 55; di-Bu, 0.38, 0.20, 47; diallyl (dial), 0.15, 0.06, 60, Et-allyl, 0.18, 0.1025, 43; Pr-allyl, 0.175, 0.072, 59; iso-Pr-allyl (allonal), 0.125, 0.0525, 58; Bu-allyl, 0.27, 0.075, 72; iso-Bu-allyl, 0.175, 0.0525, 70; sec-Bu-allyl, 0.09, 0.0375, 58; iso-Am-allyl, 0.17, 0.085, 50. C. J. WEST

Mechanism of vagus inhibition as produced by adrenaline. W. J. R. HEINEKAMP. *J. Pharmacol.* **26**, 385-96(1925).—Eserine lowers the threshold of vagus stimulation. Adrenaline effects inhibition of the heart before and after section of the vagi and after nicotine, but not after atropine. The slowing is more pronounced after a sensitizing dose of eserine. This action under the conditions of these expts. is a synergistic action of eserine. The inhibition is not due to central stimulation by the blood pressure but seems to be a direct stimulation of the parasympathetic nerve app. in the heart. The site of action of adrenaline, whether on the sympathetics or parasympathetics, depends on which set of nerves has the lower threshold, adrenaline acting on that one. C. J. WEST

I—ZOÖLOGY

R. A. GORTNER

The mucoproteins of the snails, *Helix aspersa* and *Helix pomatia*. P. A. LEVENE. *J. Biol. Chem.* 65, 683-700(1925).—"The carbohydrate radical isolated from the mucoproteins of the mucus of *Helix aspersa* and *pomatia* belongs to the group of mucosins. On partial hydrolysis the polysaccharides yield the disaccharide mucosin. From the product of complete hydrolysis there were isolated H₂SO₄, chitosamine, and a volatile fatty acid. On distn. with HCl, the mucosin yielded furfural in a quantity required by the theory of the structure of this disaccharide. From the bodies of the snails a substance is obtainable which may be regarded as animal gum and which consists largely of a polygalactose, perhaps of an acetylated polygalactose. From the bodies of the snails by mere extn. with H₂O and by further treatment by the process of Pflüger and Nerking (for the isolation of glycogen) an identical polysaccharide can be isolated."

A. P. LOTHROP

Body fluids of the honey bee larva. II. Chemical constituents of the blood, and their osmotic effects. G. H. BISHOP, A. P. BRIGGS AND E. RONZANI. *J. Biol. Chem.* 66, 77-87(1925); cf. *C. A.* 18, 866.—As compared with human blood the blood of the honey bee contains more sugar during the feeding period but during pupation the sugar content reaches a level comparable to mammalian blood. Amino acids are 50% higher, proteins slightly lower and fats higher than in human blood. The inorg. P is 1070% of that in human blood, Ca 150%, Mg 800%, K 172%, Na 41%, and Cl 33%; carbonates are only slightly lower, varying with conditions. The total salt content is thus much lower. The amino acids are the most effective fraction osmotically, having twice the value of the inorg. salts. Changes in sugar content with changed activity account for a large part of the lowering of the osmotic pressure during pupation. Approx. 90% of the osmotic pressure can be accounted for by the constituents detected by analysis. Formation of unionized compds. of Ca with amino acids probably holds part of the Ca in soln. as a prepd., analyzed salt soln. ppts. at the *p_H* of the blood. "A soln. of amino acids sepd. from a casein tryptic digest has an osmotic pressure considerably higher than can be accounted for by the known constituents. It is possible that similar metabolites may be present in blood to account for the unexplained fraction of its osmotic pressure."

A. P. LOTHROP

12—FOODS

W. D. BIGELOW AND A. E. STEVENSON

Acid- and base-forming elements in foods. G. W. CLARK. *J. Biol. Chem.* 65, 597-600(1925).—Data are given on the amts. of acid- and base-forming elements in the following foods: white and Graham bread, Graham crackers, shredded wheat, rice, whole milk, cheese, canned roast beef, eggs, fresh green peas and string beans, peeled raw potatoes, tomatoes, raisins, dried apples, dried prunes, apple base jelly. The data are in the nature of a supplement to the material presented by Sherman, Forbes and others and presumably indicate the effects that different soils and climate might have upon the mineral content of the various foods. Most of the materials analyzed were California products which were used during 2 extensive expts. in adult mineral metabolism.

A. P. LOTHROP

Viscosity studies with Nebraska wheat flours. M. J. BLISH AND R. M. SANDSTEDT. *Cereal Chem.* 2, 191-201(1925).—Coeffs. of correlation were computed for loaf vol. and each of the following factors, resp.: actual viscosity with and without removal of electrolytes, ratio of viscosity to protein content both with and without removal of electrolytes. The correlation between viscosity and protein content also was computed. There was a decided positive correlation between loaf vol. and protein content, although it was rather low. A positive correlation of the same order between actual viscosity (without preliminary removal of electrolytes) and loaf vol. was found. In case of the removal of the electrolytes there was a slight positive, but lower correlation between loaf vol. and ratio of actual viscosity to protein content. The positive correlation between actual viscosity and protein content was rather high. Therefore, for

this series of flour, protein content would have been just as valuable a constituent for predicting baking strength as knowledge of actual viscosity. Constant "b" suggested by Gortner as a measure of gluten quality was detd. for 19 flours. Diastatic power and glutenin were detd. for each of these flours. From these data either of two conclusions is possible: (1) No generally known viscometric procedure has been perfected by means of which gluten strengths of Nebraska flour may be predicted with reasonable accuracy; (2) there is some important factor aside from gluten quality—as measured by viscometric procedure—glutenin content, or diastatic value which detcs. baking strength in Nebraska flours

RUTH BUCHANAN

Hydrogen ions and their application to mill control. H. E. WEAVER. *Cereal Chemistry* 2, 209-12(1925).—The desirability of maintaining a uniform H-ion concn. in various grades of flour led to the making of observations and recording of results for a period of more than 3 years. The change in H-ion concn. occurs on different crops and during different seasons, and does not lend itself to mill control by blending or selection. The tempering process affects the H-ion concn. of wheat but little when carried to a period of 36 hrs. Longer periods of tempering might be the cause of unsound and musty flour. The tempering process offers no means of controlling H-ion concn. of mill products. The Alsop process of bleaching effects a slight increase in the H-ion concn. of a flour; Cl effects a substantial increase in H-ion concn. The use of Agene or Novadel is without effect

R. B.

Viscosity and baking quality. E. E. SMITH. *Cereal Chemistry* 2, 179-89(1925).—Ten flours covering a wide range of viscosity and baking quality and of known grade and origin were studied. A Sheely pipet was used for viscosity detn. Viscosities detd. by leaching out sol. constituents do not seem to possess any more merit than those detd. in flours without leaching. All flours of high viscosity were of excellent baking quality. Flours of low viscosity ranged from excellent to poor in baking quality, except possibly in the case of short and standard patents, within each of which grades there seems to be some correlation between viscosity and baking quality

R. B.

A study of methods of determining loaf volume of bread. W. O. WHITCOMB. *Cereal Chemistry* 2, 305-10(1925).—The efficiency of the more commonly used methods employed in measuring bread was studied. Standard loaves made from wood and enameled so as to make them impervious to water were used. Of the methods tested three depend on displacement of seeds and one depends on the displacement of water after the loaf has been waterproofed. Rape, flaxseed, sweet clover, millet, vetch and wheat were seeds used for displacement. Millet and peas showed the greatest variation in range of 3 or more readings while the peas showed the greatest deviation from the standard. Millet and sweet clover showed the least deviation from the standard. It is not practicable to measure vol. closer than 10 cc. Greater deviation was noticed in the use of different measuring devices than in different seeds.

RUTH BUCHANAN

Effects of diastase and malt extract in dough. F. A. COLLATZ and O. C. RACKH. *Cereal Chem.* 2, 213-27(1925).—Exptl. data show that the Lintner value of a flour is not an accurate index of its converting powers in a dough. With the flour as a substrate, an accurate idea of the reducing sugars which will be formed in a dough can be obtained. When diastatic malt is added to a dough, a large amount of conversion takes place in mixing, this being evidenced by a soft, wet or sticky dough. The addition of diastatic malt ext. to flours of av. baking strength apparently decreases the quality of the resulting bread.

RUTH BUCHANAN

The composition of cakes. W. C. LUCKOW. *Baking Tech.* 4, 296-9(1925).—Analyses are given of gold, silver, sponge, chocolate layer and devil's food cakes as put out by a large firm. Between bread and cake from the caloric standpoint there is very little difference

RUTH BUCHANAN

The composition of pies. Wm. C. LUCKOW. *Baking Tech.* 4, 209-12(1925).—Moisture, fat, ash, N-free ext., total sugar, starch and calories per lb. as calcd. from analyses are about the same for the fruit pies. Moisture and fat of custard with coconut are somewhat higher. The N-free ext., starch and total sugar are about the same for the fruit pies but somewhat lower for coconut with custard and custard pies. This may be accounted for in part by the fact that the fruit pies had 2 crusts and the others 1.

RUTH BUCHANAN

Report of Committee on Methods, American Association of Cereal Chemistry. C. E. MANGELS. *Cereal Chem.* 2, 235-51(1925).—Chemists are requested to report 2 decimal places for moisture, 3 for ash and 2 for protein. A tolerance between 2 different labs. of 0.3% moisture, 0.02% in ash (if same method is used) and 0.25% on protein when calcd. to a uniform moisture basis is allowable. Methods for moisture should specify a definite time of heating rather than heating to const. wt. and direc-

tions for cooling in a desiccator should be made more specific as to time. It is recommended that different methods of standardizing acids for Kjeldahl detn. be studied collaboratively and also the viscosity of flours. The effect of time and temp. on the capacity of boric acid to fix ammonia is to be studied
RUTH BUCHANAN

Hygroscopic moisture of cereal grains and flaxseed exposed to atmospheres of different relative humidity. D. A. COLEMAN AND H. C. FELLOWS. *Cereal Chemistry* **2**, 275-87(1925).—Wheat responds readily to changes in humidity of the surrounding air, the rate depending entirely upon the conditions of exposure. Protein content or percentage of dark hard and vitreous kernels shows no relation to the hygroscopic moisture. The hygroscopic moisture of samples of different market classes of wheat does not vary appreciably. The hygroscopic moisture in corn, oats, barley, buckwheat, rice and rye does not differ much from that of wheat, but flaxseed contains appreciably lower percentages of hygroscopic moisture than the cereal grains which were studied. Hygroscopic moisture does not increase at a uniform rate when in equil. with increasing relative humidity of the atm. Each increment of increase in humidity is accompanied by an acceleration in the rate of increase in content of hygroscopic moisture. The curve resulting from plotting humidity as abscissas against hygroscopic moisture as ordinates takes the form of a parabola.
RUTH BUCHANAN

Variation in the composition of milk. TOCHER. *Scottish J. Agr.* **8**, 70-1(1925).—Of a total of 750 samples of milk from as many individual cows, 10% contained less than 3% butter fat and 24% contained less than 8.5% of solids other than fat.
K. D. JACOB

Acidity-reduction in cream for butter making. The use of bicarbonate of soda. G. M. VALENTINE. *New Zealand J. Agr.* **31**, 1-8(1925).—A general discussion with particular reference to the precautions necessary in the use of NaHCO_3 for reducing the acidity of cream.
K. D. JACOB

Effect of projecting staples on butter packed in "four-one" boxes. ANON. *New Zealand J. Agr.* **31**, 31(1925).—Galvanized Fe staples in direct contact with butter packed in wooden boxes and placed in cold storage for 6.5 months were corroded but the butter around the staples was not discolored, possessed no marked taste, and contained only a trace of Zn. Fe wire staples under the same conditions were badly rusted, and discolored the butter for a distance of 0.25 in. One layer of paper reduced the rusting and corrosion and two layers afforded complete protection.
K. D. JACOBS

Variation in the composition of cheese. BERRY. *Scottish J. Agr.* **8**, 70(1925).—The av. compn. of the dry solids in samples of Scottish, New Zealand and Canadian Cheddar cheese, resp. collected during 1924 was as follows: fat 51.10, 33.30, 51.60; protein 39.90, 36.90, 39.20; fat:protein ratio 0.77, 0.69, 0.76; ash 5.90, 5.20, 5.50; moisture on original 35.70, 32.60, 29.70.
K. D. JACOBS

Cheese standards. ANON. *Scottish J. Agr.* **8**, 70(1925).—From the results of analyses of domestic cheese it is concluded that a standard of 50% fat is, on the whole, too high for Scotland.
K. D. JACOBS

Disinfecting and washing citrus fruit. II R. SHIVER. *Chem. Met. Eng.* **32**, 812(1925).—In the recently developed procedure for washing and disinfecting citrus fruit with solns. of soap and borax (C. A. **19**, 555) the use of hard water develops a greyish cast on the surface of the fruit. Investigations carried out in a packing plant where the use of these solns. made up from hard water could not be generally adopted because of complaints from the fruit-markets showed that Ca and Mg salts were deposited on the fruit during the process. In using soft water this difficulty is eliminated.
D. THUESSEN

Requirements of pectin for the commercial jelly maker. ELOISE JAMESON. *Ind. Eng. Chem.* **17**, 1291-2(1925).—The necessity of using exact proportions of ingredients in order to form an ideal jelly is emphasized. The technic of jelly making is described. The following topics are discussed: (1) high jelling power, (2) standardized jelling power, (3) a pH value when in soln. below 7 but high enough so that it will not make a jelly without additional acid, (4) ability to cause quick setting of jelly, (5) neutrality of color and flavor for mfg. fine flavored jellies and jams—for low-grade jellies pectin preps. with fruit flavors may be desired, (6) ability to make a clear soln., (7) ease of use, (8) stability during storage and use.
I. W. RIGGS

Use of sodium nitrite in curing meats. W. L. LEWIS, R. S. VOSE AND C. D. LOWRY, JR. *Ind. Eng. Chem.* **17**, 1242-5(1925).—The usual amt. of NaNO_2 may be replaced by 0.1 its wt. of NaNO_2 in curing hams, bacon, tongues and beef. Much work remains to be done before the new agent can be applied with assurance to all types of cured meats.
L. W. RIGGS

Fish meals. I. The nature of the water-soluble nitrogen compounds. W. L.

DAVIES. *J. Soc. Chem. Ind.* **44**, 487-91T(1925).—The distribution of N and acidity in 2 "yellow" meals (A, B), 3 "white" meals (C, D, E) and a fish manure (F) is, resp. NH₄ N 1.96, 2.94, 2.37, 2.17, 2.10, 1.58; other volatile base N 0.38, 1.70, 0.99, 1.39, 1.20, 0.56; other alc.-sol. N 7.86, 10.26, 8.64, 11.84, 12.10, 3.51; alc.-insol., H₂O-sol. N 11.50, 25.50, 11.00, 24.40, 21.10, 22.65; insol. protein N 78.30, 59.60, 77.00, 60.20, 58.20, 71.70; volatile acids (as AcOH) 11.52, 7.08, 0.93, 0.15, 1.42, —; non-volatile acids (as lactic acid) 1.00, 0.93, 1.13, 0.95, 0.92, —. By "other alc.-sol. N" is meant a fraction contg amino acids and polypeptides and other higher protein degradation products sol. in alc. By "alc.-insol., H₂O-sol. N" is meant a fraction contg a small quantity of sol. protein, and alc.-insol. proteoses, peptones, and polypeptides. The amt. of the simpler degradation products of proteins is larger in the "yellow" than in the "white" meals, while the latter contain more of the higher protein-fission products, which is attributed to the prolonged drastic treatment to which the former type of meal is subjected. The detn. of volatile fatty acids shows that more decompos. of fat and of amino acids has occurred in the "yellow" meals. A. PAPINEAU-COUTURE

A study of the process of making clamp silage. A. AMOS AND H. E. WOODMAN. *J. Agr. Sci.* **15**, 44-53(1925).—An investigation of the changes occurring during the preservation of the oat and tare crop in the clamp silo reveals that the material in the silo may be divided into 3 types: an upper thick layer of moldy material, a "sweet" silage in the middle layers and a wet "sour" silage in the bottom layer. The loss of dry matter in the "sour" silage layer amounted to 1/5 of the dry matter of the drop originally in that layer and was accompanied by a heavy destruction of carbohydrates. The loss in dry matter in the sweet layer was much smaller and was comparable in magnitude with that occurring during the production of "green fruity" silage in tower silos. Chem. characteristics of the "sour" silage were a high proportion of volatile bases to amino acids, and volatile acids were present in appreciable excess of non-volatile org. acids. Crude protein of this silage consisted to an appreciable extent of NH₄ compds. of org. acids of inferior nutritive value. Fiber was in excess of the amt. of carbohydrates present. R. B. DEEMER

The feeding of cows. Steamed bone flour as a mineral supplement for milk cows. A. C. McCANDLISH. *Scottish J. Agr.* **8**, 55-7(1925).—Steamed bone meal, fed at the rate of 0.5 lb. per cow per day as a supplement to the regular ration, produced an av. increase of 2% in the fat content of the milk but did not alter the total milk production and produced no significant variation in the acidity and rate of coagulation of the different samples. K. D. JACOB

The variation in moisture and N content of the potato (FAGAN) 11D. Evaporator for milk (U. S. pat. 1,562,713) 1. Filter for milk (U. S. pat. 1,563,904) 1.

ROUSSET, H.: **Conserves alimentaires.** Paris: Desforges, Girardot & Cie. 253 pp. 13.50 fr. Reviewed in *Chimie et industrie* **14**, 820(1925).

Food composition. E. MONTI. U. S. 1,563,515, Dec. 1. A fruit ext., e. g., grape pomace ext., after treatment to effect predigestion of proteins, is mixed with a substantially equal quantity of torrefied flour, and with flavoring, sugar and baking powder, and the mixt. is dried at a temp. not exceeding 100°.

Bran food. J. L. KELLOGG. U. S. 1,564,181, Dec. 1. A mixt. of bran with malt or other diastatic material is moistened and heated to convert the bran starches into malt sugars. The product is then cooked, dried, disintegrated and toasted.

Sterilizing canned foods. W. B. FENN. U. S. 1,563,971, Dec. 1. The contents of a can are subjected to steam under pressure and the steam under pressure is sealed within the can. The can and its contents are preliminarily subjected to a vacuum to prep. it for the subsequent steam treatment.

Esters of fatty acids. R. H. MCKEE. U. S. 1,542,513, June 16, 1925. Artificial food products for use in treating diabetes and acidosis comprise dihydroxy-alc. esters of fatty acids of odd-number of C atoms, e. g., glycol esters of fatty acids contg. 11 to 19 C atoms. The fatty acids are first prepd. synthetically and are then esterified, e. g., with glycol by heating to about 150° *in vacuo* or in a current of CO₂.

Cooking and extracting vegetable substances. C. R. MABEE. U. S. 1,565,282, Dec. 15. Moistened material is subjected to alternate compression and expansion, (e. g., by the action of a screw conveyor within the extn. app.) while heated and under superatm. pressure, in order to break down the starch granules and fiber structures, effect a partial conversion into sugars and render the product more assimilable. An

app. is described adapted for the treatment of sugar cane, fodder, hay or other vegetable materials for prepg. foods for human or animal consumption. U. S. 1,565,283 specifies a somewhat similar process in which the material under treatment may be heated and passed successively (first at about 95° and then at about 100°) through steam-jacketed tubes contg. screw conveyers.

Treating flour with benzoyl peroxide and similar compounds. T. KROEBER. U. S. 1,565,375, Dec. 15. Benzoyl peroxides or other similar compds. used for treating flour or like substances are comminuted to a fineness not larger than that of particles of ordinary flour (*c. g.*, by the method described in U. S. 1,555,805 (*C. A.* 19, 3491)) before use as specified in U. S. 1,380,334 (*C. A.* 15, 3349) to increase their effectiveness of action.

Dough. L. N. EARL. U. S. 1,563,694, Dec. 1. A special formula (in which both baking powder and yeast are used) is given for prepg. a dough which may be marketed as such for making biscuits, rolls, etc., and which may be kept for several days before use at temps. such as those used for keeping fresh meats.

Preserving fruits. J. G. MAGAW and A. S. MAGAW. U. S. 1,564,599, Dec. 8. Fruits and berries are preserved (without addn. of H₂O) by adding dextrose to them, subjecting the mixt. to a freezing temp. and maintaining approx. a zero temp. until ready for use.

Composition for preserving eggs. C. C. SHAFER. U. S. 1,562,854, Nov. 21. Eggs are coated with a mixt. formed from heavy petroleum oil, gum damar, Burgundy pitch, cerasin wax, Japan wax and sugar or other carbohydrate.

Desiccating eggs. C. E. BARNHILL. U. S. 1,563,953, Dec. 1. Egg yolks and albumin are sep'd. and the albumin is exposed in the form of a thin suspended film so that both sides of the film are subjected to the drying action of a warm air current.

Treating milk. A. W. BOSWORTH and L. H. CHRYSLER. U. S. 1,563,891, Dec. 1. Milk is treated with NaH₂PO₄ or other substance contg. the PO₄ radical under such conditions as still to leave the casein of the milk in soln., the milk is rendered slightly alk. so that Ca in the milk is converted into insol. Ca phosphate, the latter is removed, and any undesired excess of alkali remaining in the milk is neutralized. This treatment is adapted for prepg. milk for feeding infants.

Apparatus for pasteurizing milk in bulk. D. C. KERCKHOFF and R. COPP. U. S. 1,563,905, Dec. 1.

Chocolate-flavored milk beverage. S. J. DAVIS. U. S. 1,563,020, Nov. 24. A mixt. of milk, sugar and chocolate is heated to about 70° for 15 min., homogenized at about the same temp. under 2000 lbs. pressure per sq. in., and sterilized.

Food. H. S. MELLORT. U. S. 1,564,262, Dec. 8. Chocolate flavor is added to coned milk and the resulting mixt. is homogenized while warm, cooled, sweetened and subsequently sealed in containers and sterilized.

Bleaching chocolate. J. B. BARNITT. U. S. 1,563,682, Dec. 1. Ground, roasted cacao nib from which the cacao butter has been largely expressed is treated with a slightly alk. H₂O₂ soln.

Renovating butter. R. KAISER. U. S. 1,541,150, June 9, 1925. Inferior or rancid butter is decomposed in milk and the cream regenerated is churned again after addn. of a mixt. of butyric acid obtained from pure butter and butyric ether. The rancid butter and milk are heated and homogenized together before sep'n. of the cream.

Apparatus for reducing the offal of slaughterhouses to grease and tankage. H. P. TAYLOR. U. S. 1,567,014, Dec. 22.

Deoxidizing enclosed atmospheres. C. J. RODMAN. U. S. 1,557,092, Oct. 13. To deoxidize the gaseous contents of elec. transformer tanks or the like, there is used a mixt. or alloy of Mg 20 and Pb 80% or other metal reactive with O and an inert material such as asbestos. This mixt. is coated with a protective material such as asbestos.

Dehydrating emulsions by externally charged particles. W. MEREDITH. U. S. 1,562,712, Nov. 24. In breaking *emulsions of petroleum* with H_2O or similar emulsions, electrically charged particles such as H_2O particles are added to the emulsion and facilitate coalescence and sepn. of H_2O present in the emulsion.

Separating fibrous material from liquids. W. F. BOYSEN. U. S. 1,557,797, Oct. 20. In forming abrasive wheels, artificial lumber or other articles of fibrous material by extg. the liquid through a perforated forming device, a reagent (such as a neutralizer for pulp contg. acid) is drawn through the material by the suction device, followed by the impregnation of the material with an adhesive or cementing compn. by similar action.

Pulverizing fibrous vegetable materials. E. B. PUTT. U. S. 1,565,864, Dec. 15. Paper pulp or similar fibrous material is immersed in a dil. acid, e. g. H_2SO_4 , and heated until the fiber settles, filtered out from the acid, washed, dried and pulverized. The product thus obtained is adapted for use in dentifrices, cosmetics and other compds.

Drying and conditioning leather or other substances by heated air currents. G. D. HARRIS. U. S. 1,564,566, Dec. 8.

Drying and oxidizing paper, rubber, hides or other materials. G. D. HARRIS. U. S. 1,564,565, Dec. 8. Mech. features.

Composition for producing lachrymating gases. D. B. BRADNER. U. S. 1,565,899, Dec. 15. Chloroacetophenone is combined with fuel material including nitrocellulose to produce an effective concn. of lachrymating gas in non-persistent form by combustion and volatilization. The materials may be packaged in the form of cartridges with fuses attached.

Waterproof heat-insulation. J. H. STONE. U. S. 1,564,797, Dec. 8. A lagging for refrigerating pipes, etc., comprises granulated cork 6-24, loose hair 1-4 and rubber (dissolved in C_6H_6) 1-4 parts.

Insulating material. I. LILIENFELD. U. S. 1,563,205, Nov. 24. An elec. insulating material is formed from cellulose ethyl or benzyl ether or other cellulosic ether in admixt. with a hydrocarbon material of high b. p. and non-conductive character or with various other substances.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Water resources of California. PAUL BAILEY. *J. Am. Water Works Assoc.* 14, 309-14(1925).—A general article covering seasonal variation in vol. and unequal geographical distribution.

D. K. FRENCH

Characteristic water supply struggles in West Virginian cities. E. S. TISDALE. *J. Am. Water Works Assoc.* 14, 331-6(1925).—An historical study of the struggle in West Virginia to control water-borne typhoid fever through treatment of its water supply.

D. K. FRENCH

The salinity of artesian waters of lower and middle Belgium. (Second note). J. DELECOURT. *Ann. soc. geol. Belgique* 48, B41-B52(1925); cf. *C. A.* 19, 231.—The main flows of Belgium and France may be divided into 4 distinct zones: (1) The southern zone of hard waters. French hardness is 20-30°. The saline residue rarely exceeds 500 mg. per l. The water is drinkable. (2) Zone of precipitation. Intermediate between 1 and 3. Diminished hardness. Residue, 1 g. per l. Suitable for use. (3) Saline zone. Ca salts are absent. Characterized by presence of alk. salts. Hardness less, alk. residue 1-3 g. per l. Not recommended for use. (4) Zone of super-salinity. Chlorides of Ca and Mg, also of the alkalis, are present. Saline residue is greater than 3 g. per l. Totally unfit for use.

WM. B. PLUMMER

Water supply of the city of Los Angeles with particular reference to the area supplied by pumps. WM. W. HURLBUT. *J. Am. Water Works Assoc.* **14**, 379-83(1925).—General and descriptive. D. K. FRENCH

Softening public water supplies. J. C. WHITE. *J. Am. Water Works Assoc.* **14**, 106 19(1925).—The Porter-Clark and zeolite processes are discussed with especial reference to the value of a softened water to the consumer. D. K. FRENCH

New Lackawanna water station shows low operating cost. H. W. MACHEMER. *Railway Rev.* **77**, 354(1925); *Railway Eng. Maintenance* **21**, 377.—The D. L. & W. R. R. recently rebuilt their water station at Groveland, N. Y. The lime and soda ash treating facilities consist of an intermittent plant with air agitation and subsequent filtration through pressure filters. Three 85,000-gallon steel tanks are used for treatment. A 4-hr. sedimentation period is provided. R. C. BARDWELL

Chlorophenol tastes in Milwaukee's water supply. R. W. CUNLIFFE. *J. Am. Water Works Assoc.* **14**, 423-33(1925).—Because of intermittent epidemics of objectionable odor and taste in its supply, Milwaukee conducted an extended search for the source of impurities which on chlorination were responsible. Phenol, Semet-Solvay and coal-gas plants were found to be the chief offenders. Methods of disposal are outlined. D. K. FRENCH

Missouri-Kansas-Texas improves water supplies. J. H. DAVIDSON. *Railway Age* **79**, 415; *Railway Eng. Maintenance* **21**, 309(1925).—A comprehensive program for improvement of water supply quality on the M. K. & T. R. R., extending over the system has shown marked improvement in locomotive performance. Prior to 1916 various boiler compds. were used with inconsistent results. At the close of 1923, 35 complete lime and soda ash softeners and 52 soda ash plants were in service, at 60% of the water stations, and 65% of water used was treated. The complete softeners are of the continuous type with various feeding arrangements. Reduction in boiler failures has amounted to between 85% and 97%. Saving in fuel varies from 6% to 14% for different class of service. Improved water conditions have helped to make possible the increase in continuous locomotive run of from 275 to 869 miles. Photographs, diagram and charts are included. R. C. BARDWELL

Providing a railroad's water supply. R. C. BARDWELL. *Railway Age* **79**, 517, 585 (1925).—Increasing attention given to water quality and pumping equipment is reducing railway transportation costs. Various features of treating and pumping equipment are discussed. R. C. B.

Water supply for textile mills. C. L. HUBBARD. *Textile World* **68**, 2891-4(1925).—Water clarification and softening for textile mills is discussed. CHAS. E. MULLIN

Treated water increases locomotive efficiency. R. C. BARDWELL. *Railway Rev.* **77**, 669; *Railway Age* **79**, 769(1925).—General paper on methods of water softening as applied to railway use. Estd. figures are given on consumption and cost data. R. C. B.

Amounts of soap and builder necessary to soften water of different degrees of hardness. H. B. ROBBINS, H. J. MACMILLAN AND L. W. BOSART. *Ind. Eng. Chem.* **18**, 27-9(1926).—An attempt is made to point out the most economical procedure to be followed where hard water must be used in laundry work. The general conclusion is that for max. economy soda ash should first be added with agitation; a little time should be allowed for it to react with the water before addn. of the soap. The amt. of soda to be added varies with the hardness of the water. EDWARD BARTOW

The "OMS" purifier, a new clarification process for industrial waste water. OTTO MOHR. *Apparatebau* **37**, 304(1925); 1 cut.—An improved Dorr thickener with a small tank attached to the bottom in which is a cylindrical vessel, open at the top into which most of the mud raked from the thickener falls and from which it is withdrawn through a pipe entering the top of the inner vessel. Part of the mud enters at the bottom of this vessel also (cf. *C. A.* **18**, 874). J. H. MOORE

Treated water in swimming pools. F. H. STOVER. *J. Am. Water Works Assoc.* **14**, 440-1(1925).—The danger of contaminated water and the harmless nature of its treatment are emphasized. D. K. FRENCH

Composition of mud balls. W. S. MAHLIE. *J. Am. Water Works Assoc.* **14**, 420 2(1925).—Org. matter, SiO₂, and oxides of Fe and Al were the principal ingredients. There was no relation between size and compn. D. K. FRENCH

Reconstruction of filters at Louisville. W. H. LOVEJOY. *J. Am. Water Works Assoc.* **14**, 352-6(1925).—A general descriptive article. D. K. FRENCH

Sensitivity of the o-tolidine and starch-iodide tests for free chlorine. A. M. BUSWELL AND C. S. BORUFF. *J. Am. Water Works Assoc.* **14**, 384-405(1925).—A

very thorough research comparing the two methods under virtually all conditions. Although the tests are equally sensitive the authors recommend the *o*-tolidine test on account of the stability of the reagent and the simplicity of the method, and because it is less affected by certain interfering substances. D. K. FRENCH

Standard methods of water analysis (rept. of Comm. no. 1). J. J. HINMAN, JR., et al. *J. Am. Water Works Assoc.* **14**, 343-7 (1925).—No important changes are contemplated in the 1915 Standard Methods. A résumé is given of research work in progress as well as of that recommended. D. K. FRENCH

The behavior of magnesium chloride in boiler feed water. J. H. VOGEL. *Kali* **19**, 394-6 (1925).—A controversial review. The deleterious effects of $MgCl_2$ in boilers are not caused by the splitting of HCl , but by other phenomena (cf. V. Die Abwasser aus der Kaliindustrie, Berlin, 1913, p. 250). WM. B. PLUMMER

Physical properties of boiler scale. G. PARIS. *Chimie et industrie* Special No., 138-42 (Sept. 1925).—A description of various types of scale according to their constituents and mode of formation. A. PAPINEAU COUTURE

Experiences with small service pipes. J. E. GIBSON. *J. Am. Water Works Assoc.* **14**, 295-308 (1925).—In a plea for better service pipes G. covers present practice of installation, and considers the many different metals used in pipe material and the uses for which they are best fitted. In the discussion, the uses of copper pipe and the "Admiralty" alloy are mentioned. D. K. FRENCH

Protection of steam boilers against scale and corrosion. R. CAILLOL. *Chaleur et industrie* **6**, 357-62, 419-24, 469-74 (1925).—A review and discussion of the relative merits and drawbacks of the various processes of feed-water purification and of protection of the inside of boilers against scaling and corrosion. A. PAPINEAU COUTURE

Iron incrustation in water pipes: the responsibility of iron algae. DAVID ELLIS. *Water and Water Eng.* **27**, 352-4 (1925).—Hard nodules found in water pipe were sepd from the pipe wall by the tar coating giving the impression that material came from water rather than from the pipe and was probably due to algae. Although the organisms were present and iron sufficient for their growth was contained in the water, formation of nodules in this way could not be demonstrated. It was shown that tar coating was porous to water and the iron came from the pipe. Soft slimy deposits may be due to bacteria and iron from water. E. has never found hard nodules in wood pipe. JACK J. HINMAN, JR.

The corrosion of iron pipe lines. GUSTAV WIEGAND. *Gas u. Wasserfach* **68**, 731-4 (1925).—Conditions existing in a no. of German cities are described and preventive measures discussed. WM. B. PLUMMER

Electrolytic conductivity and hydrogen-ion control of waste disposal. H. C. PARKER. *Water & Water Eng.* **27**, 445-8 (1925).—See C. A. **19**, 2716. H. G.

The relation between drinking water and goiter. W. VON GONZENBACH. *Gas u. Wasserfach* **68**, 667-71 (1925).—A general discussion of the distribution of goiter in Central Europe, of its effects, particularly the causation of habitual miscarriage in case both of female animals and women, and of its prevention. WM. B. PLUMMER

Iodine treatment in Michigan. E. D. RICH. *J. Am. Water Works Assoc.* **14**, 325-30 (1925).—Accepting the idea that goiter is caused by a deficiency in iodine, a comprehensive study of the state supplies was made and a map shows the distribution of available iodine. Various methods of making up I deficiencies are outlined and its general distribution in table salt is considered the best and most logical. D. K. F.

Destruction of lice (*Pediculus corporis*) on the body or on clothing by soapy emulsions of the oleoresin of the pyrethrum of Dalmatia. A. JUILLET and H. DIACONO. *Bull. sci. pharmacol.* **32**, 413-28, 464-78 (1925).—Soapy emulsions of the oleoresin of *Pyrethrum cinerarifolium* Trev. make an excellent lice killer. Insecticides made by pulverizing the heads of the plant are of little use. The oleoresin is best extd in a thermo-centrifuge with trichloroethylene as the extg. liquid. The alkyl. of the soapy emulsion is important and should be equiv. to 0.8 g. $NaOH$ per 100. Less alkyl., neutrality, and to a greater degree, acidity prevent the toxic action. K soaps are preferred to Na soaps. The quantity of pyrethrum ext. (obtained by C_2HCl_3) should not be less than 0.252 g. per 100 cc. of the prepd. emulsion. The presence of C_2HCl_3 in the emulsion is an advantage, the optimum concn. being 0.8 g. C_2HCl_3 per 100 cc. The duration of contact of the emulsion should be not less than 20 min. Pyrethrum exts. are harmless to man but toxic to insects, therefore, they are suggested as a prophylactic measure against those diseases which are transmitted by lice. L. W. RIGGS

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

Modern tendencies in soil research. G. W. ROBINSON. *Welsh J. Agr.* 1, 130-4 (1925).—A discourse. K. D. JACOB

Soil studies on the waste lands of Lleyn. H. T. JONES AND G. W. ROBINSON. *Welsh J. Agr.* 1, 142-7(1925).—The phys. and chem. characteristics of 3 types each of dry and wet waste soils of Wales are summarized. K. D. JACOB

Alkali investigations in the Sudan. A. F. JOSEPH. *J. Agr. Sci.* 15, 407-19(1925).—This investigation covers a period of over 10 yrs. and deals with the area in Sudan known as the Gerzira, the soils of which consist of a brown heavy clay rather high in water-sol. salts and possessing considerable alk., the origin of the soil being acolian. Samples taken at the same time from good and bad plots in the same area show a strong correlation between salt content and crop-yielding power. There is also a strong correlation between p_H and fertility. R. B. DEEMER

The problem of soil acidity in North Wales. RICH WILLIAMS. *Welsh J. Agr.* 1, 135-41(1925).—The typical soils of North Wales are derived from rocks devoid of CaCO_3 and consequently they are usually acid in reaction. The p_H of the ordinary fertile soils varies from 5.6 to 6.8. They are highly buffered and are considered "unsatd." with respect to Ca, the lowland soils usually contg. much more available Ca than the upland soils. K. D. JACOBS

The available phosphate in soils. E. VANSTONE. *J. Agr. Sci.* 15, 460-5(1925).—A modification of Dyer's method for detg. available P_2O_5 is proposed. Results on soils of known agricultural history obtained by shaking 20, 40, 60 and 80 g. of soil for 30 mins. in 500 cc. of a 1 and 2% $\text{C}_6\text{H}_5\text{O}_7$ soln. are compared with results by Dyer's method. The value of the ratio of sol. P_2O_5 /total P_2O_5 is especially studied. R. B. DEEMER

The exchangeable bases in some Scottish soils. A. M. SMITH. *J. Agr. Sci.* 15, 466-75(1925).—The exchangeable Fe, Al, Ca, Mg, K, and Na are reported for 20 soils from different parts of the east of Scotland, detn. is made by extn. with $\text{N NH}_4\text{Cl}$ soln. Data on p_H , "lime-requirement" and loss on ignition are given for comparison. Until a sufficient no. of soils have been examd. and classified it is concluded that it is unlikely that any satisfactory generalization on the subject will be forthcoming. R. B. DEEMER

Studies in soils reaction. III. The determination of the hydrogen-ion concentration of soil suspensions by means of the hydrogen electrode. E. M. CROWTHER. *J. Agr. Sci.* 15, 201-20(1925); cf. *C. A.* 19, 2098.—A H electrode app. is described. Closely related soils may show considerable difference in p_H value, with no change in their degrees of buffer action, as indicated by titration curves with lime water. While these lime requirements are correlated with the p_H values, in dissimilar soils no such relationship holds. Neutral salts increase the H-ion concn. of both acid and slightly alk. soils. Na salts give lower H-ion concn. than the corresponding K or Ca salts, and chlorides give lower p_H values than sulfates. The degree of buffer action is unaffected by the addn. of a neutral salt. Previous extn. with H_2O causes a considerable increase in the p_H value of its suspensions. A no. of soils showed an increase of about 0.1 p_H for twofold diln. The "salt effect" and "diln." effect appear to be of the same type. It is recommended that the soil-water ratio of 1:5 be generally adopted. The indicator methyl red gives erroneous p_H values in turbid soil suspensions because of the absorption of the red form, which is apparently a cation capable of undergoing "base exchange" with the soil. R. B. DEEMER

Cohesion in colloidal soils. F. HARDY. *J. Agr. Sci.* 15, 420-33(1925).—Resistance to (a) transverse breaking, (b) crushing and (c) parting under tensile pull of standard blocks of soil are reported in this investigation. Three highly colloidal siliceous soils contg. ants. of CaCO_3 ranging from 7.2 to 0.2% and 2 lateritic soils were examd. The most significant results were obtained by employing, in a special tenacity app., granular test-blocks, prepd. by moistening sieve-graded dry soil packed into rectangular molds. It is believed that results thus obtained furnished a reliable measure of the

cohesiveness of soil colloidal matter, especially in soil blocks brought to a const. moisture content in a humidifier. The method of prepn. simulates the effect of rain in causing the "running together" of colloidal soil particles. "The relative cohesiveness of the soils examd. appears to follow the same order as their rates of settling from aq. suspension. This observation strengthens the view that cohesiveness in colloidal soils is to a certain extent due to chem. forces that depend on the presence of active atoms or at. groups possessing powerful fields of residual affinity, although probably film tension also plays a part."

R. B. DEEMER

Percolation in colloidal soils, considered in relation to swelling and cohesiveness. F. HARDY. *J. Agr. Sci.* 15, 434-43 (1925).—The results of expts. on the rate of horizontal flow, and on the rate of gain in mass, of kerosene and of water in fine and crumb fractions of certain West Indian colloidal soils, comprising 3 siliceous soils contg. different amts. of CaCO_3 and 2 lateritic soils are described and tabulated.

R. B. D.

Studies in the physical properties of soils. II. A note on the cohesion developed by capillary forces in an ideal soil. W. B. HAINES. *J. Agr. Sci.* 15, 529-35 (1925); cf. *C. A.* 19, 2097.—"Using the conception of the 'ideal soil' a calcn. has been made of the cohesion due to the capillary attraction between the particles when wetted. Exptl. verification of this theory is afforded by cohesion tests on the ignited silt fraction sepd. from soil." **III. Observations on the electrical conductivity of soils.** *Ibid* 536-43.—H. proposes to overcome difficulties in soil resistance measurements encountered by previous workers in this field by using a fluid (Hg) contact with the soil.

R. B. D.

Soil structure in relation to non-capillary and capillary porosity and its significance in soil fertility. A. G. DOVARENKO. *Sci. J. Agronomy* (Russia) 1924, No. 7-8.—Of all the physico-chem. properties which characterize the soil in the dynamics of its biophysicochem. processes the capillary and non-capillary porosity and their relations play a decisive role. The effectiveness of either one of the above causes such processes as moisture and air penetration, moisture-holding capacity, capillary rise, evapn., relation of moisture and air, biol. activities, accumulation of available plant food, properties of the soil soln., osmotic pressure, concn. and degree of elec. dissociation, H-ion concn., gas exchange and the phenomenon of soil and atm. electricity. The various vapors, fertilization and effectiveness of long-continued grass culture are a reflection in the character of the porosity on one hand and on the corresponding dynamics of the biophysicochem. processes on the other hand. The soil structure appears to be an inherent factor of the fertility of the cultivated land.

J. S. JOFFE

The relationship between the vapor pressure and water content of soils. A. N. PURI, E. M. CROWTHER AND B. A. KEEN. *J. Agr. Sci.* 15, 68-88 (1925).—The water contents of a characteristic series of soils, when in equil. with the atm. of different humidities, were detd. by 2 methods. Results are substantially the same by both. Absorption at definite relative humidities is almost independent of temp. over the range 20° to 40° for high relative humidities, but decreases with increasing temp. for lower relative humidities. Hysteresis is noted in all soils. The apparent water content increases regularly with the temp. of heating up to 200° . Heated to temps. between 100° and 200° , soils show substantially the same water absorption at different relative humidities. Reagents known to disintegrate the soil markedly affect this absorption. Addition of salts to the soil and vapor-pressure curves of soil fractions also are reported.

R. B. DEEMER

A simple method of obtaining the size distribution of particles in soils and precipitates. DONOVAN WERNER. *Trans. Faraday Soc.* 1925, advance proof.—Use is made of a glass tube $1\frac{1}{2}$ cm. in diam. and $1-1\frac{1}{2}$ m. long. A suspension of the material is placed in the tube and the velocity of sedimentation measured as the velocity with which the height of the sediment increases. This height is read off on a scale alongside the glass tube with the aid of a magnifying glass. The measurement of this velocity of the sedimentation gives an accumulation curve and from this curve the size distribution can be calcd. by the method developed by Oden (*C. A.* 10, 2429). From tests made with sand, clay and SrSO_4 crystals, it is concluded that the method can be used for particles as large as $100-150\mu$ and as small as 10μ , or less, providing there is a sufficient quantity of the material available to permit the detn. of the increase of the sediment height.

W. H. ROSS

The movement of soil moisture. A. F. LEBEDIEV. *Ann. Don Agr. Inst.* (Russia) 3, 1-220 (1919).—A comprehensive survey with original expts. The following are discussed: theory of Folger, condensation of water vapor of the atm. in the upper soil layers, the movement of water vapor in soils and subsoils, the movement of water under the influence of mol. forces and under the influence of gravity, and the origin of subsoil water.

J. S. JOFFE

Dephenolization in soils. II. N. N. SEN-GUPTA. *J. Agr. Sci.* **15**, 497-515 (1925); cf. *C. A.* **15**, 3167.—The results and conclusions refer to the nature and the cause of the disappearance of phenol and the cresols in soils previously treated with acid. The elucidation of this cause suggests the possibility of associating the instantaneous loss in untreated soil and the slow chem. loss with the same cause. Results are, however, conflicting, but on the whole they lend support to the hypothesis that all the various types of dephenolization are due fundamentally to 1 agent, MnO_2 . R. B. D.

A method for determining the degree of humification of soil organic matter. G. W. ROBINSON AND J. O. JONES. *J. Agr. Sci.* **15**, 26-9 (1925).—Since H_2O_2 (6% soln) seems completely to oxidize soil org. matter, or at least brings it into a sol. state, and is without action upon fibrous org. substances it is proposed to use this method for estg. the approx. degree of humification of soil org. matter. In soils so far examd. the highest degree of humification is found in peats and uncultivated soils. The degree of humification may possibly be correlated with the prevalence of anaerobic conditions.

R. B. DEEMER

The determination of nitrogen in heavy clay soils. D. V. BAL. *J. Agr. Sci.* **15**, 454-9 (1925).—In the detn. of N by the Kjeldahl method certain heavy black cotton soils of the Central Provinces, India, gave higher results when the soil was moistened with H_2O prior to digestion with H_2SO_4 . Fifty cc. of H_2O were used for this moistening, CuSO_4 and K_2SO_4 being added when decompn. of the acid commenced. These soils apparently contain a cementing material probably contg. Fe insol in H_2SO_4 which protects the org. matter in the interior. It is suggested that this may be a source of error in many soil N detns.

R. B. DEEMER

Advances in the fertilizer industry in the years 1921 to 1924. G. WICHERN. *Chem.-Ztg.* **49**, 885-6, 893-5 (1925).—A review with bibliography.

E. J. C.

Soil nutrients in relation to vegetation and reproduction. E. J. KRAUS. *Am. J. Botany* **12**, 510-6 (1925).—Some phases of the problem are discussed in the light of present knowledge.

P. R. DAWSON

The lime factor of production. BACHALA. *Prog. agr. vit.* **84**, 327-32 (1925). A discussion of the role of lime in the soil, its importance as a plant nutrient, and its effects upon the assimilation of nutrients and the reaction of the soil.

P. R. DAWSON

Lime in viticulture. L. SOURSAC. *Prog. agr. vit.* **84**, 467-9 (1925). A résumé and discussion.

P. R. D

Influence of the soil reaction upon the absorption of phosphorus and potassium in the presence of various phosphatic fertilizers. ANTONIN NEMEC AND MIHOVIL GRAČANIN. *Compt. rend.* **181**, 194-6 (1925).—Flat-bottom crystg. dishes, contg. 100 g. of soil, 0.05 g. P_2O_5 , from different sources and 200 g. pure sand washed free of nutrients with HCl and water, were planted with 100 grains of rye each. After 18 days the amts. of P and K in the roots and stalks of the seedlings were detd. Much more of the P_2O_5 of superphosphate was absorbed in an acid than in a neutral medium. With Constantine mineral phosphate, bone meal, Reitmeir's reform phosphate and tetraphosphate, there was generally a greater absorption with a more acid condition. On acid soils the plants absorbed more K than in those slightly alk. Superphosphate favored the highest absorption of K, particularly on acid soils.

P. R. DAWSON

Recent experiments to determine the fertilizer requirements of a soil. FRITZ MARTIN. *Centr. Zuckerind.* **33**, 1112-5 (1925).—The familiar methods for estg. soil acidity or lime requirement are described and discussed, *i. e.*, the Comber, Hasenbäumer and Daikuhara methods. Neubauer's methods for the detn. of P_2O_5 and K in soils are similarly treated.

P. R. DAWSON

The use of high concentrations of potassic fertilizers. L. HAUMONT. *Prog. agr. vit.* **84**, 491-7 (1925).—In an expt. conducted in Belgium with forage beets manure alone yielded 33,500 kg. per hectare. The application of 1000 kg. NaNO_3 , 1000 kg. superphosphate and 1000 kg. Thomas slag per hectare increased the yield to 79,450 kg.; while the same application with the addn. of 2500 kg. of 14% sylvinit gave a return of 124,420 kg. Such results are attributed to the fact that with high concns. of K the absorbing power of the soil is exceeded and the relatively slow diffusion of this nutrient is overcome, leaving a large excess for immediate assimilation. One heavy application followed by normal concns. is recommended.

P. R. DAWSON

Fundamental investigations on basic slags. MCARTHUR. *Scottish J. Agr.* **8**, 72-3 (1925).—The results of pot and field tests indicated that under particular soil conditions the dicalcium silicate present in open-hearth, fluorspar basic slag can function as an ingredient for the correction of soil acidity. It is stated that the mol. compn. of a slag, particularly as regards the combinations of P, Si and Ca, is of more importance than the actual percentage compn. The work is being continued.

K. D. JACOB

Basic slags and mineral phosphates. E. VANSTONE. *J. Agr. Sci.* **15**, 36-46 (1925); cf. *C. A.* **19**, 2255.—The relationship between phosphate sol in 2% CaH_2O_8 and total P_2O_5 was investigated. Phosphate of known compn., basic slags and mineral phosphates were examd. This relationship when shown graphically is, in nearly all these cases, a straight line passing through the origin. In 3 slags of wide citric soly., the soly. is a const. independent of the wt. taken, if allowance is made for a small const. analytical error. Exceptions are noted. Results are confirmed by pot tests. Comparisons are made of basic slags, superphosphates and steamed bone flour with mineral phosphates. R. B. DEEMER

A new method of evaluating basic slags and mineral phosphates. E. VANSTONE. *J. Agr. Sci.* **15**, 491-6 (1925). The cause of low soly. in CaH_2O_8 of phosphates is the increasing concn. of sol. Ca citrate formed from the combined lime in the basic phosphate, and between this sol. Ca citrate and the phosphate that has become sol. a reversed reaction takes place which can be prevented by using an acid, such as $\text{C}_2\text{H}_2\text{O}_4$, which will form an insol. salt. Pot expts. with beans are given, which support the conclusion that the rate of soln. in $\text{C}_2\text{H}_2\text{O}_4$ indicates the rate at which P_2O_5 is taken up by the plant. R. B. DEEMER

Basic slag and grassland. ANON. *The Fertiliser, Feeding-Stuffs and Farm Supplies J.* **10**, 661 (1925).—The compn. of 10 samples of high-grade, and fluor spar slags varied as follows: total P_2O_5 17.2 to 42.5, P_2O_5 as fluorapatite 0 to 26.9, and citric acid-soly. 16.4 to 98.4%. The citric acid-soly. of the slags varied inversely as the amt. of fluorapatite present, the latter being calcd. from the F content. K. D. JACOB

The value of mineral phosphates to British agriculture. C. B. GREENING. *The Fertiliser, Feeding-Stuffs and Farm Supplies J.* **10**, 161-5 (1925).—A résumé of expts. with ground raw rock phosphate as a fertilizer. K. D. JACOB

Manufacture of dicalcium phosphate. R. DECKERT. *Chem.-Ztg.* **49**, 789-90 (1925).—The process of prep. CaHPO_4 from low-grade continental phosphate rock is described. The essential steps consist of preliminary drying, grinding, digestion with 20% HCl to liberate the H_2PO_4 , filtration, pptn. with milk of lime, filtration and drying. The product contains 40% citrate-sol. P_2O_5 , out of a total of 41%, is light and easy to distribute, and can be stored indefinitely without deterioration. P. R. DAWSON

Fertilizing in relation to the disease resistance of crops. BRYNMOR THOMAS. *The Fertiliser, Feeding-Stuffs and Farm Supplies J.* **10**, 487-8 (1925). In one expt. the percentage of healthy potato plants was increased from 42.7 on the control plots to 54.1 on plots receiving K_2SO_4 at the rate of 200 lb. per acre. In another expt. the percentage increased from 28.5 to 58.8. The lower-grade K_2O salts were much less efficient in this respect than either the chloride or sulfate. Application of superphosphate at the rate of 600 lb. per acre to a soil already contg. unusually large amts. of available P_2O_5 decreased the percentage of healthy plants from 59.6 on the control plot to 26.6. Although an excess of N usually decreases the disease-resisting powers of plants, T. was able to obtain a progressive increase in the percentage of healthy potato plants with applications of $(\text{NH}_4)_2\text{SO}_4$ up to 800 lb. per acre supplied as a balanced fertilizer with potash and superphosphate. Potash is the detg. factor in promoting the disease resistance of plants. N and P_2O_5 , particularly the former, are liable to exercise an adverse effect when used in excessive amts. Each variety of plant has a certain definite ratio of K_2O , N and P_2O_5 which is the optimum for increasing its disease-resisting powers. The importance of maintaining this ratio is emphasized. K. D. JACOB

A preliminary study of the relationship between fertilizing and susceptibility to disease in potatoes. H. W. MILES AND B. THOMAS. *J. Agr. Sci.* **15**, 89-95 (1925).—Influence of N, K and P, compd. fertilizer and gypsum upon potatoes was studied. Excessive N applications favor the incidence of disease in this crop. The quantity of nitrogenous fertilizer applied may be regarded as excessive only when not balanced by adequate amts. of K_2O . Also the capacity for resistance varies directly with the quantity of K_2O . Some of the forms of K_2O are more effective than others. Heavy dressings of a well-balanced compd. fertilizer tend to increase the immunity of the crop to disease. R. B. DEEMER

The value of calcium cyanamide as a fertilizer. H. J. PAGE. *Fertiliser, Feeding-Stuffs and Farm Supplies J.* **10**, 871-3 (1925).—A general discussion with particular reference to vegetation expts. K. D. JACOB

Results of tests of plant protecting agents in 1921-1924. A. KÖLLIKER. *Chem.-Ztg.* **49**, 654-5, 674-5, 700-1, 774-5, 790-2 (1925).—The results are summarized of comprehensive tests upon a wide variety of com. preps. and chem. reagents as to their

fungicidal and insecticidal efficacy against various pests. Lab. methods of evaluation are described and discussed.

P. R. DAWSON

Notes on experimental work. Weed destruction by spraying. ANON. *The Fertiliser, Feeding-Stuffs, and Farm Supplies J.* 10, 523-4(1925).—The no. of weeds on a heavily infested plot of barley were greatly reduced in comparison with the check plots by spraying with a 50% soln. of $(\text{NH}_4)_2\text{SO}_4$ at the rate of 37.5 gallons per acre. Plots sprayed twice with the same amt. of soln. as above each time were practically free from weeds at the end of 4 weeks.

K. D. JACOB

The scientific control of pests and diseases (of plants). THEODORE PARKER. *The Fertiliser, Feeding-Stuffs and Farm Supplies J.* 10, 593-4, 666-7(1925).—A discussion of certain of the chem. factors concerned in the application and effect of sprays, washes and dusts

K. D. JACOB

Dry treatment for smut diseases of cereals. KATHLEEN SAMPSON AND D. W. DAVIES. *Welsh J. Agr.* 1, 169-76(1925).—A review of exptl. work on (1) the use of dry Cu carbonate to control bunt of wheat, (2) the use of Cu carbonate to control seed-borne diseases other than bunt of wheat, and (3) the use of dild. Cu carbonate and other chem. dusts. A bibliography of 33 references is appended.

K. D. JACOB

Stinking-smut of wheat. III. Field germination tests of seed treated with formalin and Clarke's wheat protector. J. C. NEILL. *New Zealand J. Agr.* 31, 24-5(1925); cf. *C. A.* 19, 2722.—Samples of seed wheat were dipped in formalin, 1 pint of com. formalin contg. 39% formaldehyde to 40 gallons H_2O , and in a soln. of 1 lb. of Clarke's Wheat Protector in 1.5 gallons and allowed to drain and dry slowly. The formalin treatment caused an immediate loss in germination of 5% on 1-year old seed. The loss progressively increased to 26% on storage of the seed for 3 weeks prior to planting. Germination of new seed was only slightly reduced. Clarke's Wheat Protector increased the percentage germination of both new and 1-year old seed, and storage for 3 weeks had no appreciable effect on germination in either case.

K. D. JACOB

A new process for disinfecting seed. W. E. FISCHER AND K. SCHARER. *Chem.-Ztg.* 49, 757-8(1925).—The use of solvents of a lower b. p. than water eliminates the difficulties of drying dipped seed. Immersion of flax seed for 0.5 to 1 hr in C_2HCl_3 or CCl_4 produced very satisfactory results and improved germination.

P. R. DAWSON

Methods of combating chestnut blight. J. DUFRENOY. *Cuir tech.* 14, 490-5(1925).—Chestnut blight is caused by an organism (*Blepharospora cambivora* Petri) which gains entrance through the roots. Individual trees may be saved by cutting off infected roots, and disinfecting the soil with CuSO_4 . This method is impractical on a large scale. The only feasible method for combating the disease is the replacement of susceptible with immune species.

H. B. MERRILL

The preparation of emulsions of mineral oils in cupric sprays for winter treatment of fruit trees. A. PAILLOT. *Prog. agr. vil.* 84, 405-6(1925).—The formula recommended consists of 2 kg. CuSO_4 , 4 kg. $\text{Ca}(\text{OH})_2$, 10 l. petroleum and 90 l. water. Directions for prepn. and application are given. The type of oil used for automobile motor lubrication is very well adapted to this purpose, but waste oils are not as satisfactory.

P. R. DAWSON

The chemical effect of the addition of a "spreader" to the mixed lime sulfur-lead arsenate spray. W. GOODWIN AND H. MARTIN. *J. Agr. Sci.* 15, 476-89(1925).— CO_2 of the air produces sol. As in mixed lime S-Pb arsenate spray and the effects of casein, lime, lime-casein and gelatin were studied. Casein increases the amt. of sol. As but has no effect upon the polysulfide S. The addn. of lime caused a decrease in sol. As but also reduced the fungicidal value of the spray on account of the reaction with S liberated from CaS . The effect of lime-casein is influenced by the amt. of lime or casein in the mixt. The use of gelatin increased the sol. As but had no effect on the reaction of CaS . All of these reagents retard the rate of decompn. of the spray.

R. B. DEMER

Poisonous sprays and fruit contamination. ANON. *The Fertiliser, Feeding-Stuffs, and Farm Supplies J.* 10, 455(1925).—A blue powder present as a thin coating on com. apples contained CuSO_4 14.0, As_2O_3 1.5, and Ca salts, etc., 84.5%. The powder resulted from spraying with Bordeaux mixt. and was not present in sufficient amt. to be considered dangerous to health.

K. D. JACOB

Effect of sulfur upon nitrogen content of legumes. J. R. NELLER. *Ind. Eng. Chem.* 18, 72-3(1925); cf. *C. A.* 20, 87.—Both elemental S and gypsum increase the N content of alfalfa 32 to 44% and of clover 10 to 23%. Since the crop yield was increased, the total increase in fixed N was very great. The S content of the crop is sometimes increased.

J. J. WILLAMAN

A test of the tobacco powder and lime mixture for the destruction of warble mag-

gots. H. W. THOMPSON. *Welsh J. Agr.* **1**, 206-7(1925).—Two treatments with a mixt. composed of 1.5 lbs. fresh lime, 4 lbs. tobacco powder and 1 gallon H_2O applied at 3-day intervals killed an av. of 74.5% of the maggots infesting 95 cattle in 6 herds.

MURRAY, J. ALAN: **The Science of Soils and Manures.** 3rd ed. revised and enlarged. London: Constable & Co., Ltd. 298 pp. 12s. 6 d. net. Reviewed in *Industrial Chemist* **1**, 407; *Chem. News* **131**, 220(1925).

Treating seed grain. A. SCHMIDT, A. STEINDORFF, A. FLUSS and O. SCHAFFRATH. U. S. 1,565,237, Dec. 8. Equal amts. of a 0.2% aq. soln. of the hydrochloride of diaminodihydroxyarsenobenzene and a 0.2% aq. soln. of $CuSO_4$ are used for treating seeds by immersion for a period of about 1 hr., to destroy parasites. $HgCl_2$ and other org. As compds. also may be used.

16 THE FERMENTATION INDUSTRIES

C. N. FREY

Processes for the production of absolute alcohol. RENÉ PIQUE. *Chimie et industrie Special No.*, 200 16(Sept. 1925).—A review of processes proposed, more particularly of those which have been used commercially.

A. PAPINEAU-COUTURE

The dehydration of alcohol by lime. PÉRARD AND GRIMAUD. *Chimie et industrie Special No.*, 217-20(Sept. 1925).—Tables and curves are given showing the rate of dehydration at various temps. of EtOH of different strengths when mixed with different quantities of lime of various strengths (76-97% CaO). Cannot be abstracted

A. PAPINEAU-COUTURE

The dehydration of alcohol. III. L. GAY AND A. MASSOL. *Chimie et industrie Special No.*, 221-33(Sept. 1925); cf. *C. A.* **18**, 3519.—In a preliminary study of the miscibility of the gasoline-EtOH- H_2O system G. and M. detd. and plotted the miscibility isotherms at 20° and at 5°. The method used (described in detail) consisted essentially in adding to an initially homogeneous mixt. of known compn. maintained at const. temp. one of the constituents until the appearance of permanent cloudiness. The method is extremely sensitive and allowed of measuring solubilities as low as 0.003% of gasoline in the mixt. A study of the dehydrating action on aq. alc. of satd. solns. of $(NH_4)_2SO_4$, $Na_2S_2O_4$, KF and K_2CO_3 showed that the latter is the only one that is suitable. A study of the dehydrating action of satd. K_2CO_3 on EtOH-gasoline mixts. showed that with gasoline-EtOH mixts. contg. less than 15% gasoline, it is best to dehydrate separately the aq. alc. and a gasoline-alc. mixt. contg. 15% gasoline, and to mix the dehydrated liquids in the desired proportions. With a mixt. contg. more than 15% gasoline, it is best to dehydrate the mixt. directly. The results on the whole are applicable to other dehydrating agents; but the proportion of gasoline below which it is preferable to dehydrate the 2 separately will vary according to the dehydrating agent and according to the compn. of the gasoline.

A. PAPINEAU-COUTURE

Industrial alcohol from agaves. II. BOULARD. *Chimie et industrie Special No.*, 234-9(Sept. 1925).—A discussion showing the ease with which industrial alc. could be cheaply produced as a by-product from the treatment of agave for the production of textile fiber (sisal).

A. PAPINEAU-COUTURE

Composition of yellow oil obtained in the manufacture of *n*-butyl alcohol by fermentation. C. S. MARVEL AND A. E. BRODERICK. *J. Am. Chem. Soc.* **47**, 3045-51 (1925).—The high-boiling residue from the manuf. of BuOH (about 0.5 to 1% of the total yield of solvents) is a dark amber liquid with the odor of crude BuOH. It is a mixt. of BuOH, active AmOH, iso-AmOH, $C_6H_{13}OH$, and the butyric, caprylic and capric esters of these alcs. The alcs. were identified by conversion to the α -acid esters of 3-nitrophthalic acid. The *Am ester* m. 132-3°, the *hexyl ester*, 121-2°. Twelve l. of crude yellow oil gave: 5.1 l. of BuOH, 220 cc. mixed AmOH, 100 cc. hexyl alc., 700 g. $PrCO_2H$, 12 g. caprylic acid, 28 g. capric acid. The solid product suspended in the oil is a mixt. of the Fe and Cu salts of these acids.

C. J. WEST

Acid production during fermentation of sugar by yeast in the presence of calcium carbonate. S. KOSTYCHEV and L. FREY. *Z. physiol. Chem.* **146**, 276(1925); *Wochschr. Brau* **42**, 217-8. -In the presence of CaCO_3 and $(\text{CH}_2\text{COOH})_2$ and absence of N, acetic and malic acids are found. $(\text{CH}_2\text{COOH})_2$ is produced from glutamic acid by yeast as follows: $\text{CH}_2(\text{COOH})\text{CH}_2\text{CH}(\text{NH}_2)\text{COOH} + \text{O}_2 = (\text{CH}_2\text{COOH})_2 + \text{CO}_2 + \text{NH}_3$. Acetic acid is probably produced from AcH. The production of malic acid is difficult to explain. It is not believed acetic and malic acids are produced by bacteria associated with yeast. If glutamic acid breaks up in the following way: (1) $\text{CH}_2(\text{COOH})\text{CH}_2\text{CH}(\text{NH}_2)\text{COOH} + \text{O} = \text{CH}_2(\text{COOH})\text{CH}_2\text{COCOOH} + \text{NH}_3$; (2) $\text{CH}_2(\text{COOH})\text{CH}_2\text{COCOOH} \rightarrow \text{CH}_2(\text{COOH})\text{CH}_2\text{CHO} + \text{CO}_2$; (3) $\text{CH}_2(\text{COOH})\text{CH}_2\text{CHO} + \text{O} \rightarrow (\text{CH}_2\text{COOH})_2$; then possibly aspartic acid should give: (1) $\text{CH}_2(\text{COOH})\text{CH}(\text{NH}_2)\text{COOH} + \text{O} = \text{CH}_2(\text{COOH})\text{COCOOH} + \text{NH}_3$; (2) $\text{CH}_2(\text{COOH})\text{COCOOH} \rightarrow \text{CH}_2(\text{COOH})\text{CHO} + \text{CO}_2$; (3) $\text{CH}_2(\text{COOH})\text{CHO} + \text{O} \rightarrow \text{CH}_2(\text{COOH})_2$. However, carboxylase does not split $\text{CH}_2(\text{COOH})\text{COCOOH}$ as it does $\text{CH}_2(\text{COOH})\text{CH}_2\text{COCOOH}$ to 1 CO_2 per mol., but yields 2 mol. of CO_2 and 1 of CH_2CHO , the latter being then reduced to $\text{C}_2\text{H}_5\text{OH}$ or oxidized to CH_3COOH . Probably $\text{CH}_2(\text{COOH})\text{COCOOH}$ is reduced and forms $\text{CH}_2(\text{COOH})\text{CH}(\text{OH})\text{COOH}$. A small amt may arise as shown by Thunberg from $(\text{CH}_2\text{COOH})_2$, $(\text{CH}_3\text{COOH})_2$ + 2HM, M being methylene blue, and $(\text{CH}_3\text{COOH})_2 + \text{H}_2\text{O}$ yields $\text{CH}_2(\text{COOH})\text{CH}(\text{OH})\text{COOH}$. C. N. FREY

The soaking of barley. A. REBOUL. *Brasserie et malterie* **15**, 261-5(1925).—When barley is put in water the reaction of the latter gradually changes. If acid is gradually added so as to maintain the p_{H} const. at 4.5, the no. of cc is proportional to the sq. root of the time in hrs.; and if alkali is gradually added to maintain the p_{H} const. at 8.5, the no. of cc is proportional to the time. The p_{H} of the water used for soaking barley has no effect on the absorption of water nor on the germination of the barley.

A. PAPINEAU-COUTURE

The barleys of 1925. J. RAUX. *Brasserie et malterie* **15**, 275-81(1925).—Analyses of barleys produced in different parts of France are tabulated and commented on.

A. PAPINEAU-COUTURE

The stability of beer. A. FERNBACH. *Ann. brass. dist.* No. 22(1925); *Bull. assoc. inst. sup. fermentations Gand* **26**, *Ann. soc. brassieurs* **34**, 337(1925).—Acidity has a greater effect on stability than the nature and amt. of the proteins. Beer with low assimilable N will not keep well if the p_{H} is high; while even with a high assimilable N it will keep well if the p_{H} is sufficiently low. Similarly hops will exert a protective action only with a low p_{H} .

A. PAPINEAU-COUTURE

The function p_{H} in brewing. MARC H. VAN LAER. *Chimie et industrie* **14**, 511-8(1925).—A review.

A. PAPINEAU-COUTURE

Cooking of beer worts with steam. J. D. WILLEMART. *Chimie et industrie* **14**, 686-90(1925).—From a discussion of various methods of boiling worts, W. brings out the advantages of heating by means of an open coil, and the importance of proper and efficient agitation of the liquid from the standpoint of improving both the flavor and stability of the beer.

A. PAPINEAU-COUTURE

The function of hydrogen-ion concentration in the preparation and conservation of wines. J. VENTRE. *Ann. école agr. Montpellier* **18**, 88-99(1925); *Chimie et industrie* **14**, 776(1925).—General discussion.

A. PAPINEAU-COUTURE

Solutions of ammonium sulfophosphate in vinification. GASTON CHEVALIER. *Rev. vit.* **63**, 325-30(1925).—A study of the data on the subject leads to the conclusion that, while SO_2 in variable concns. appears to be indispensable in all vinifications, on the contrary NH_4 phosphate should be used only very judiciously in the case of musts deficient in this respect or in naturally slow or depressed fermentations, and not as a general practice, as must be done when NH_4 sulfophosphate solns. are applied.

P. R. DAWSON

Action of oxygen gas on wines. L. E. GRANDCHAMP. *Chimie et industrie Special No.*, 561-4(Sept. 1925); cf. Picdallu, Malvezin and G., *C. A.* **14**, 3748; G., *C. A.* **18**, 3249. —After briefly reviewing the work of Pasteur and Berthelot on the function of O in the aging of wines, G. discusses the action of O in preventing "casse" (pptn. in the wine subsequent to clarification) and its effect on the bouquet of the wine. New wine contains relatively large quantities of esters which are not easily oxidized, while the bouquet of aged wines is due to the gradual development of easily oxidizable aldehydes. Treatment in the cold of new wines with sufficient O (introduced by means of a Chamberland filter over which the wine is made to circulate slowly in a thin film) completely to ppt. the substances which can produce the "casse", followed immediately by filtration of the wine, does not prevent development of the bouquet on aging. It at most gives a slight flat taste which is not persistent.

A. PAPINEAU-COUTURE

The various methods of preserving, aging and refining wines. P. MALVEZIN. *Chimie et industrie Special No.*, 565-73 (Sept. 1925).—After briefly reviewing other methods and agents, M. brings out the advantages of the use of allyl mustard oil (cf. M. and Bidart, *C. A.* 18, 438; Delage, *C. A.* 18, 439; Roos and Hugues, *C. A.* 19, 698; Moreau and Vinet, *C. A.* 19, 699).

A. PAPINEAU-COUTURE

Variation in the sulfurous acid content of grape musts. L. MOREAU and F. VINET. *Chimie et industrie Special No.*, 578-81 (Sept. 1925).—For a given must and under given conditions, after addn. of SO_2 a certain proportion of the latter gradually combines with the constituents of the must and part remains free. The reaction is complete after 30 days (except for a very slow oxidation of residual free SO_2 under certain conditions), and it is 90% complete in 3 days. With increasing addns. of SO_2 , up to 2 g. per l., the amt. of residual free SO_2 (which alone is efficient as a preservative) increases proportionally to the total SO_2 added, above a certain min. addn. which varies with the must and conditions of treatment. M. and V. show how this can be used for detg. the amt. of residual free SO_2 which will remain after a given addn. of total SO_2 under given conditions, and conversely how much SO_2 must be added to obtain a given free SO_2 content.

A. PAPINEAU-COUTURE

Oxidation and aeration of wines in casks. J. DUBAGUÉ. *Chimie et industrie Special No.*, 606-7 (Sept. 1925).—A brief review of the modern conception of the mechanism of the action of O and CO_2 in the aging of wine.

A. PAPINEAU-COUTURE

Theory and practice of the clarification of wines. L. MATHIEU. *Chimie et industrie Special No.*, 608-14 (Sept. 1925).—A review.

A. PAPINEAU-COUTURE

Sanitation in the wine industry. H. DELAUNAY. *Chimie et industrie Special No.*, 615-8 (Sept. 1925). The chief factors of improper sanitation in wine handling and storage plants are poor ventilation, humidity and darkness, which are generally considered essential to proper aging of the wine. Sanitary conditions can be maintained without interfering with proper aging of the wine, as proved by actual conditions in some modern plants. The vapors and SO_2 given off by the wine during handling do not exert any harmful effect on the health of the workmen. There is no special disease or infirmity attributable to this occupation.

A. PAPINEAU-COUTURE

The use of sulfurous acid in the cider industry. WARCOLLIER and LÉMOAL. *Chimie et industrie Special No.*, 624-30 (Sept. 1925).—When SO_2 is added to the juice of fresh sound apples, about 50% combines with the aldehydes, sugars, etc., while with juice from damaged apples or apples having reached a very advanced stage of maturity about 90-95% of the SO_2 combines. SO_2 can be almost completely removed by boiling under reduced pressure from recently sulfited juice of fresh apples, but not from juice which has been sulfited for some time nor from the juice of damaged or over-ripe apples. SO_2 can be nearly all removed from hard cider or from cider brandy by means of charcoal, MnO_2 or PbO_2 .

A. PAPINEAU-COUTURE

The analysis of grape musts in the light of present-day knowledge and practical conclusions to be drawn therefrom. L. FERRÉ. *Chimie et industrie Special No.*, 582-8 (Sept. 1925).—A discussion of the importance, in wine making, of the total and free tartaric and malic acid contents of must and of the significance of the ratios between them.

A. PAPINEAU-COUTURE

Chemical determination of alcohol in wines and fermented liquors. ERNEST MARTIN. *Chimie et industrie Special No.*, 589-91 (Sept. 1925); cf. Astruc and Radet, *C. A.* 19, 1926.—The method consists essentially in adding 5 cc. H_2O to 1 cc. of wine, distg. (without a condenser) into standard $\text{K}_2\text{Cr}_2\text{O}_7$, and titrating the excess with standard FeSO_4 . The method is claimed to be accurate to less than $\pm 0.1\%$.

A. P.-C.

Effect of dextran on white wines made from musts affected by Botrytis (noble rot). J. C. DELAGE. *Chimie et industrie Special No.*, 592-600 (Sept. 1925).—Sauternes and Barsac wines of the 1917 vintage prepd. according to the most approved practice and bottled in 1921 became cloudy in the bottles; but if the bottles were uncorked the wine cleared up completely overnight. The compn. and taste were quite normal. The trouble was traced to a retarded pptn. of muco-cellulosic colloids which were present in the musts owing to the action of *Botrytis* on the grapes. The wines affected had been bottled after 3-4 yrs. because the stocks of bottled wines were practically exhausted, while previously they were generally bottled only after 5-6 yrs., under which conditions the dextran had practically all pptd. out.

A. PAPINEAU-COUTURE

Application of concentration to grapes and to fresh and fermented grape juice. L. ROOS. *Chimie et industrie Special No.*, 601-5 (Sept. 1925).—A brief review of work done on the concn. of wine by evapn., showing that this cannot be successfully carried out without destroying the flavor of the wine. The advantages of concn. of the fresh juice and the possible uses of the concd. juice are discussed.

A. PAPINEAU-COUTURE

Wine and medicine in antiquity. RENÉ PIQUE. *Chimie et industrie* Special No., 552-60 (Sept. 1925).—Historical, with bibliography of 94 references. A. P.-C.

Fermentation processes. A. RÖMER. U. S. 1,510,195-6, Sept. 30, 1924. See Brit. 161,870 (*C. A.* 15, 2525).

Normal butyl alcohol. F. BOINOT. U. S. 1,565,543, Dec. 15. See Can. 253,511 (*C. A.* 19, 3347).

Acetone and butyl alcohol by fermentation. G. W. FREIBERG. U. S. 1,537,597, May 12, 1925. A mash of carbohydrate material such as that from potatoes or maize is fermented with "*Bacillus butylaceticum*." Details are given of the isolation, properties and use of this bacillus. Cf. *C. A.* 19, 3347.

Yeast. S. SAK. U. S. 1,566,431, Dec. 22. A yeast-nutrient mass is filtered, the residue is washed, propagation of yeast with aeration is initiated in the wash H_2O , and, during the propagation, the original wort is added, substantially continuously.

Yeast. R. F. BACON. U. S. 1,532,858, Apr. 7, 1925. See Brit. 225,252, *C. A.* 19, 1614.

Preparation of pressed yeast. S. K. D. M. VAN LIER. Dutch 13,773, Oct. 15, 1925. Yeast on cultivation tends to metabolize first the substances that are easily assimilable, later on (forced growth) those that are more difficultly digestible. Yeast of better quality is obtained by succeeding a period of forced growth by a cultivation in an easily digestible medium (contg 10% of the totally digested sugar). Several periods of forcing either N or C metabolism may be alternately used.

Conditioning and drying yeast. F. M. HILDEBRANDT and C. N. FREY. U. S. 1,534,387, Apr. 21, 1925. In treating yeast after propagation to enable it better to retain its baking properties, the yeast is subjected to a conditioning treatment with aeration in a soln. contg sugar and nutrient salts, caused to pass into a dormant state by lowering its temp. to 0°, thawed, mixed with corn meal or the like to absorb exuded moisture, desiccated, and if desired, further desiccated after an admixt with refined mineral oil and sufficient H_2O to make a pasty mass.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Advances in the chemistry, culture and manufacture of tobacco. RICHARD KISSLING. *Chem.-Zig.* 49, 965-6, 969 (1925).—A review with bibliography. E. J. C.

Frederick Belding Power. C. L. ALSBERG. *Ind. Eng. Chem.* 18, 103 (1926).—A brief biography, with portrait. E. J. C.

Volumetric estimation of the alkaloids of opium. L. BARTHE and F. DUFILHO. *Bull. soc. pharm. Bordeaux* 63, 170-2 (1925); cf. *C. A.* 19, 2386.—The purified opium alkaloids, obtained as described in an earlier publication, and the filter upon which they have been collected are placed in a 200-cc. porcelain capsule, 25 cc. of 1 N HCl are added and the whole is triturated with a glass rod until a homogeneous mixt. is obtained. The mixt. is then transferred to a 1000-cc. graduated flask, the capsule is washed with 3 25-cc. portions of 1 N HCl and the washings are added to the contents of the flask. The capsule is then washed with 200-300 cc. of distd. H_2O in several portions, this is also added to the contents of the flask and then sufficient distd. H_2O to make 900 cc. The flask is then closed, shaken for several minutes, filled to the 1000-cc. mark and allowed to stand for 1 hr. The liquid is then filtered. To 100 cc. of the filtrate, a few drops of an alc. soln. of methyl red are added and titration is effected with 1 N NaOH. The buret reading (n) is taken and 1 cc. subtracted from this. Another 100 cc. of the filtrate is then taken, methyl red is added, followed by $n-1$ cc. of 1 N NaOH added at one time. The titration is completed by adding 0.1 N NaOH drop by drop. If, e. g., 9 cc. 1 N NaOH + 7.1 cc. 0.1 N NaOH are required, the total corresponds to 9.71 cc. of 1 N NaOH. Then $10-9.71 = 0.29$ cc. N HCl combined with the alkaloids in 100 cc. of filtrate and $0.29 \times 10 = 2.9$ N HCl combined with the total alkaloids in 5 g. of opium. Expressed as anhyd. morphine of which the coeff. is 0.285, the results for 100 g. of opium will be $0.285 \times 2.9 \times 20 = 16.53$ g. A. G. D.

Some tests for the identification of veronal sodium. CLÉMENT GÉNOT. *J. pharm. Belg.* 7, 701-5 (1925).—G. gives the various solvents in which veronal sodium is sol. and those in which it is insol., the various forms of crystals obtained from various solvents and numerous chem. tests and color reactions are given. A. G. DUMÉZ

Researches on the fermentation of dried tobacco. I. Methods for separating

nicotine and ammonia. ANDOR FODOR AND ADOLF REIFENBERG. *Biochem. J.* **19**, 827-9(1925).—The tobacco leaves are steam distd., the mixt of NH_3 and nicotine in the distillate is acidified with H_2SO_4 , pptd. with HgI_2 in KI (2 g. per 100 cc.)—under which conditions NH_3 gives no ppt.—the ppt. allowed to remain overnight and washed by decantation, and the N in it detd. The NH_3 is distd. from the filtrate in the usual way. **II. The enzymic production of volatile products from nicotine under the influence of tobacco-leaf extracts.** *Ibid* 830-5.—The fermentative effect is greater with unfermented tobacco leaves allowed to dry naturally than with tobacco obtained by drying rapidly. The greater part of the activity disappears during the fermentation process.

BENJAMIN HARROW

Thiosept oil. E. BELANI. *Petr. Z.* **21**, 1439(1925).—The shale oils of Tirol (Austria) contain S compds. They are carefully distd. in the so-called Meguin retorts, where, after a quick preliminary distn., they are transferred while still hot into special retorts with elec. heating and are further distd., with vacuum and steam. The resulting "Thiosept oil" boils between 100 and 250° and has a high content of unsatd. compds. which are valuable medicines for skin diseases caused by parasites and bacteria. The next fraction is the "Sulfoscept oil" which has a sharp odor and kills insects (flies, etc.) instantly.

M. B. HART

Dependency of medicine on chemistry. J. S. HEPBURN. *Catalyst* **10**, no. 10, 1-2(1925).—The contributions of chemistry to the progress of medicine during the past century are shown by comparison of the U. S. Pharmacopeias of 1820 and 1920.

JOSEPH S. HEPBURN

Identification of alkyl derivatives of barbituric acid. ALDO ZAMPARO. *Boll. chim. farm.* **64**, 257-8(1925).—One cc. H_2SO_4 and 2 drops of 2% NaNO_2 added to 0.1 g. substance produce no reaction with diethylbarbituric acid, a gradually appearing faint yellow color in the cold and a pink one in the heat with the diallyl deriv. and with the cold and hot ethylphenyl deriv. a rapidly appearing yellow-orange, which disappears on diln.

MARY JACOBSEN

Some tests for the identification of adaline. CLÉMENT GÉNOT. *Chimie et industrie* **14**, 679-85(1925).—The phys. and chem. properties of adaline, $\text{H}_2\text{C}_6\text{BrCONHCONH}_2$, are reviewed. The microscopic appearance of the crystals obtained by evapn. at 30° of solns. of adaline in various solvents are described and illustrated. The m. p. was found to be 117°, and the m. p. in admixt. with various proportions of bromural, hedonal, sulfonal, tetronal, trional, urethian and veronal, which are the most likely adulterants, are tabulated. A large no. of microchem. and of color reactions are described. For details, the original should be consulted, as it cannot be satisfactorily abstracted.

A. PAPINEAU-COUTURE

Some chemical properties of adrenaline. G. REBIÈRE. *Chimie et industrie Special No.*, 384-9(Sept. 1925).—Adrenaline hydrochloride, neutral and acid benzoates, neutral and acid salicylates were obtained by adding the theoretical amts. of acid (HCl gas dissolved in abs. alc., BzOH and salicylic acid dissolved in Me_2CO) to the adrenaline (I) and evapn. to const. wt. at low temp. *in vacuo*. The resultant thick sirups crystallize spontaneously in time. To prep. the picrate, dissolve slightly more than the theoretical amt. of picric acid in Et_2O , add I, shake, let stand 2-3 days in a stoppered flask with frequent shaking, and filter off the yellow cryst. I-picrate. A study of the cond. (*via* Kohlrausch) of 0.01 N HCl , H_2SO_4 , H_3PO_4 , AcOH , salicylic and benzoic acids on addn. of increasing quantities of I showed that neutralization of the acid takes place in a similar manner to neutralization by the strong bases. With H_3PO_4 there are formed both mono-adrenaline di-H and di-adrenaline mono-II phosphates. A study of the p_{H} of 0.01 N HCl , AcOH and oxalic acid gave the same indications as the cond. but the increase in p_{H} with excess of I is not as sudden as with water-sol. alkalis. The addn. of small quantities of I (0.05 g. to 100 cc. of 0.1 N acid) to HCl and oxalic acid reduced the p_{H} . With dil. FeCl_3 solns. I salts give an emerald-green, changing to violet with alkalis (Vulpian's reaction). The limit of sensitiveness of the reaction is reached with 5 cc. of 0.1% FeCl_3 and 0.01 mg. I or with 5 cc. 0.005% FeCl_3 and 0.2 mg. I. The green color changes to red on heating, while the green obtained similarly with pyrocatechol changes to dirty gray on heating. Addn. of a few cc. of I soln. to a 0.01-0.02% HgCl_2 soln. gives a rose color on heating. With a fairly concd. HIO_3 soln. I gives a yellow color in the cold, changing to purple on heating. The reaction is sensitive to 0.01 mg. I. A reagent was prepd. as follows: 10% $\text{K}_2\text{Fe}(\text{CN})_6$ soln. 10 cc., 0.1 N NaOH 100 cc., distd. H_2O to 10 cc. (this is evidently a misprint, probably for 1 l.), dil. 1 cc. to 200 cc. The reagent gives a blood-red color with I, is decolorized on heating, turning dirty green in acids and golden yellow in alkalis. 1 cc. of the dild. reagent gives a distinct color with 0.1 mg. I; 5 cc. gives a very slight

color with 0.001 mg. I, perceptible against a white background. Addn. of 5 cc. 0.01 N I-HCl and 2 drops AcOH to 5 cc. of 5% NaNO₂ gives an orange-red color in the cold. Under the same conditions pyrocatechol gives yellow, turning red on heating. On adding 1 drop of 0.001 N I-HCl to 1 cc. 0.01 N AgNO₃ and 1 drop 0.1 N NaOH and heating to boiling, reduction takes place, perceptible against a black background. The reaction is sensitive to 0.001 mg. I, and the sensitiveness would probably be increased by examg. in the dark by means of a ray of light passing through the soln. (Tyndall effect). I can be detd. colorimetrically by the HIO₃ reaction or by the Vulpian reaction. In the latter case, the intensity of the red color obtained on heating is proportional to the I content. In the Vulpian reaction there is partial reduction of the FeCl₃, which can be measured by adding K₃Fe(CN)₆ and detg. the resultant Turnbull's blue colorimetrically. Very dil. solns. of Ag, Pd or Au salts, when heated with I, are reduced with formation of colloidal solns. which can be made remarkably stable by addn. of a suitable protective colloid. Ag and Au should be reduced in alk and Pd in neutral soln.

A. PAPINEAU-COUTURE

Introduction to the microchemical investigation of essential oils. RAOUL CRI-GHELLI. *Chimie et industrie Special No.*, 397-404 (Sept. 1925).—A discussion of the importance and necessity of working on small quantities of material (even on one plant or portion of plant) in biological investigations of essential-oil-bearing plants, and of possible methods of micro-analysis including extn. of the oils, nephelometry, colorimetry, polarimetry, refractometry, spectrometry, olfactometry, ultimate and proximate analysis and the detection of the essential oil in different parts of the plant.

A. PAPINEAU-COUTURE

Oil of lavender. ETABLISSEMENTS A. CHIRIS. *Parfums de France No. 33*, 318 (Nov. 1925); cf. *C. A.* 18, 3683; 19, 873.—Analysis of 21 samples of Italian oil of lavender and of 3 samples of English oil by P. Rovesti (*Profum. italici* (1925) 208-22) gave results for total alcs. and for total oxygenated compds. (free alcs. + esters) which practically fall within the limits previously assigned for the French oils (73-80% and 81-91%, resp.)

A. PAPINEAU-COUTURE

The sources of geraniol. ANON. *Parfums de France No. 31*, 243-51 (Sept. 1925); *No. 32*, 272-80 (Oct. 1925); *No. 33*, 302-11 (Nov. 1925). (In French and English).—Brief monograph on oils of *palmarosa*, *geranium* and *citronella*. A. PAPINEAU-COUTURE

Adulteration of oil of limes. ANON. *Parfumerie moderne* 18, 254 (1925).—Distd. oil of limes is adulterated with terpenes obtained as a by-product in the production of terpeneless oil of limes, and sometimes also with the terpenes of oil of lemon. Five samples of oil of limes adulterated in this way had: d 0.856-0.858, $[\alpha] + 39^\circ$ to $+51^\circ$, n 1.4706-1.4715. They gave only about half the normal yield of terpeneless oil.

A. PAPINEAU-COUTURE

Ether for anesthesia. F. ATHIAS. *Thesis (Algiers)*, 1924; *Chimie et industrie* 14, 744-5 (1925).—The decompn. of Et₂O is due mainly to the action of atm. O, is more rapid in the light than in the dark, occurs much less in colored or opaque containers, and can be reduced by addn. of traces of hydroquinol to pure Et₂O. A. P.-C.

Estimation of atropine. P. BOURCET. *Bull. sci. pharmacol.* 32, 585-8 (1925).—One hundred g. of the drug is pulverized to pass without residue, through an 80-mesh sieve and is mixed with 20 g. of impalpably ground CaO. The mixt. is ground in a mortar to a homogeneous mass and is extd. in a Soxhlet app with Et₂O for about 4 hrs., or until a little of the ext. acidified with 2% HCl no longer gives the Valscr reaction for alkaloids. The Et₂O ext. is cooled and is acidified with HCl up to 2%. The acid soln. is decanted through a filter and the filtrate is made alk. by NaOH in slight excess. The bases set free are extd. with CHCl₃, the CHCl₃ ext. is filtered through a filter lined with dry Na₂CO₃ and is distd. from a tared flask. The residue dried at 100° and weighed represents the total non-volatile alkaloids. The tared flask with its residue is placed in the oven at 120° for 5 hrs. in order to isomerize the hyoscyamine if present. The contents of the flask are then dissolved in boiling anhyd. Et₂O, the soln. is filtered and neutralized by an Et₂O soln. of H₂C₂O₄. The resulting ppt. of oxalates is washed with Et₂O, is dried at 100° and weighed.

L. W. RIGGS

Evaluation of ergot preparations. ALFRED BRAUN. *Arch. expil. Path. Pharm.* 108, 96-105 (1925).—In the removal of the adrenaline effect upon the rabbit uterus the effects of ergotamine are dependent upon both the concn. and the time of action.

G. H. S.

Chemical changes in pure ether. S. MATSUNAMI. *J. Pharm. Soc. Japan No. 520*, 529-39 (1925).—Pure anesthetic ether was subjected to various conditions for different times and then the production of vinyl alcohol or vinyl ether tested with Nessler reagent. If the ether is distd. with inert gas, such as N or CO₂, and kept in a brown-glass bottle,

it undergoes the least chem. change. Nessler reagent detects the formation of the aldehyde (or vinyl alcohol) in ether when the amt. of the product reaches 0.00006 g. per 100 cc. ether. Sulfurous acid-fuchsin soln. can be used as a reagent instead of Nessler soln. The negative test with Nessler reagent is almost too delicate a criterion to be used for the requirement of ether as anesthetic use. S. T.

Estimation of morphine in opium. F. MACHIGUCHI AND S. SHIRONO. *J. Pharm. Soc. Japan* No. 524, 849-61 (1925).—Add 2 g. of $\text{Ca}(\text{OH})_2$ to 8 g. of opium powder dried under 60° , shake with 80 cc. H_2O for 1 hr. and filter. Add 50 cc. of the filtrate to a thick-walled bottle (100-cc.) contg. 20 cc. $\text{Et}_2\text{O}-\text{C}_6\text{H}_6$ mixt. (8:2), and 1 g. NH_4Cl , shake for 10 min. and let the mixt. stand over 20 hrs. Collect the ppt. on filter paper (9 cm.), wash 4 times with 5 cc. H_2O , dry under 60° ; cool and wash with 20 cc. $\text{Et}_2\text{O}-\text{C}_6\text{H}_6$ (1:1). Dry the ppt. at $96-100^\circ$, dissolve in 0.1 *N* HCl , and titrate with 0.1 *N* NaOH , using 3 drops of methyl red as an indicator. The amt. of the acid used by the ppt. when multiplied by 0.5704 gives the % of the morphine in opium. By this method, M. and S. obtained 18.4239%, in a sample which gave 18.2528% according to the German Pharm., 18.8232 according to the U. S. Pharm., 18.0246 according to the Brit. Pharm., and 17.18833 according to the Japanese Pharm. S. T.

Emulsion films (HOLMES) 2. Determination of camphor (GORI) 7. Detection of Bi in organic material (DANCKWORTT, PFAU) 7. Wine and medicine in antiquity (PIQUE) 16.

KRÖMEKE, FRANZ: *Friedrich Wilhelm Sertürner, der Entdecker des Morphiums*. Jena: Verlag Gustav Fischer. 93 pp. M. 5. Reviewed in *Am. J. Pharm.* 97, 785 (1925).

Medicinal mixture. J. K. LILLY U. S. 1,562,459, Nov. 24. A mixt. of phenylcinchoninic acid with the hydriodide of phenylcinchoninic acid is used for treating arthritis.

Styptic mixture. C. R. DOWNS. U. S. 1,563,346, Dec. 1. Phthalyl peroxide 60 is used with phthalic acid 40 and a filler such as talc 100 parts.

Remedy for syphilis. S. BERGEL. U. S. 1,534,832, Apr. 21, 1925. Lipoids are repeatedly injected into parts of an animal's body most capable of resistance to syphilis (monkeys or other animals susceptible to syphilis being used). Then spirochetes contg. syphilitic material and suspended in lecithin are repeatedly injected and at the same time repeated injections are made of substances which may contain gall, Na taurocholate, saponin-contg. material or sarsaparilla. The concn. and quantities of the doses of spirochetes are gradually increased and those of the dissolving agents gradually decreased. Exudants from the animal's body caused by inflammation, exts. from the lymphatic glands, the spleen and the omentum and blood serum of the animal are collected, and lecithin is sepd. from the collected substances by filtration. The filtrate may be used alone or with arsphenamine as a therapeutic agent.

Concentrated enzymic composition adapted for therapeutic use. S. A. WAKSMAN. U. S. 1,561,385, Dec. 8. A fungus-impregnated culture medium such as one prepd. with *Aspergillus oryzae* is lixiviated with H_2O and a fresh mass of fungus-impregnated culture medium is soaked in the liquid ext. and the mixt. dried.

Chemically pure ether for anesthesia. NEDERLANDSCHE GIST EN SPIRITUSFABRIEK. Dutch 13,636, Oct. 15, 1925. Benzidine dissolved in boiling, previously purified and dried ether seps. out on cooling to $+15^\circ$ in prismatic crystals, contg. $\frac{1}{2}$ mol. ether of crystn., stable at room temp. After drying, these crystals on distn. at 100° in a stream of H_2 yield chemically pure ether. *o*-Tolidine or tetramethylbenzidine may be used instead of benzidine.

Ether for anesthesia. NEDERLANDSCHE GIST EN SPIRITUSFABRIEK. Dutch 13,637, Oct. 15, 1925. The ethereal mother liquor from the benzidine crystals (cf. preceding abstr.) after distn. gives ether suitable for anesthetic purposes.

Stable analgesic solution containing novocaine and magnesium sulfate. C. W. HOOPER. U. S. 1,563,087, Nov. 24.

Disinfectant and detergent. L. F. WHITLOCK. U. S. 1,563,604, Dec. 1. A mixt. of niter cake 90-98 and vegetable ivory 2-10 parts, in powd. form.

***d*- ψ -and-*l*- ψ -Cocaine.** O. WOLFFS and H. MAEDER. U. S. 1,534,558, Apr. 21, 1925. *d*-*l*- ψ -Ecgonine methyl ester is converted by means of optically active acids

into the corresponding salts, the *l*- ψ -salt is sepd. from the *d*- ψ -salt by fractional crystn. of the latter, and the bases are isolated and benzoylated. Detailed examples are given.

Morphine solution. C. W. HOOPER. U. S. 1,563,086, Nov. 24. A sterile stable soln. is formed of NaHSO₃ 0.1, MgSO₄ 50, novocaine 2.5, morphine sulfate 0.5 and H₂O 100 parts.

Neorsphenamine. P. A. KOBER. U. S. 1,564,859, Dec. 8. Arsphenamine base is converted into a formaldehyde sulfoxylate deriv. and the latter is pptd. and filtered off from the reaction mixt., the ppt being mixed with a strong Na₂CO₃ soln., excess of free alkali being avoided. The resulting soln. is evapd. under a pressure of 2-10 mm. Hg.

Alkylated acridinium compounds. L. BENDA. U. S. 1,565,891, Dec. 15. An alkoxyacridine, e. g., 3,6-dimethoxyacridine, is alkylated in the acridine N. Production of 3,6-dimethoxy-10-methyl (also ethyl-, benzyl-, and hydroxyethyl-) acridinium chloride is described. These products have comparatively high bactericidal properties and are of low toxicity but possess substantially no dyeing properties.

Double salts of calcium dimethylxanthine and salicylic acid. H. VIETH. U. S. 1,547,698, July 28, 1925. Therapeutic compds. of high diuretic efficiency comprise double salts of Ca (or Sr) dimethylxanthine and salicylic acid. Several neutral and basic salts prepd. from theobromine and theophylline, Na salicylate and CaCl₂ or SrCl₂ are described.

Alkylamino esters of *p*-aminobenzoic acids. O. EISELB. U. S. 1,550,350, Aug. 18, 1925. By esterifying *N*-monoalkyl- and *N*-monoalkyloxyalkyl derivs. of *p*-aminobenzoic acid with amino alcohols and by alkylating the *p*-aminobenzoic acid alkylamino esters, alkylamino esters are obtained which are of stronger local anesthetic effect than cocaine. Numerous examples and details of procedure are given.

Testing antirachitic values of cod-liver oil and other substances. T. F. ZUCKER. U. S. 1,563,134, Nov. 24. Tests of the *p_H* of the feces of rats or other test animals fed with the substance being tested indicate the antirachitic value of the substance.

Vitamin preparation. I. F. HARRIS. U. S. 1,510,883, June 9, 1925. Vitamin preps., especially preps. of H₂O-sol. vitamins such as derived from yeast, are preserved from deterioration by admixt. with lactose and galactose or other relatively non hygroscopic sugars.

Dentifrice. J. T. LELAND. U. S. 1,566,218, Dec. 15. Sep. compns. which react together to produce NaI are prepd. and used together, e. g., a mixt. of CaCO₃, I and glycerol and a mixt. of NaCl, starch, menthol and liquid soap.

Perfume. A. CORTI. U. S. 1,565,796, Dec. 15. Nitrodibromobutyl-*m*-cresol methyl ether, m. 100°, has an odor resembling musk and "a true smell of ambergris." It may be made by treating dibromobutyl-*m*-cresol methyl ether with a mixt. of HNO₃ and H₂SO₄ at 5-10°.

Embalming fluid. E. BARTA. U. S. 1,565,773, Dec. 15. HgCl₂, NaCl, NaOH, thymol, camphor, "eosin rubrum," formol, "concd. formaldehyde" and oil of bergamot are used.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

FRED C. ZEISBERG

The development and present position of the Chilean saltpetrer industry. PAUL KRASSA. *Z. angew. Chem.* 38, 921-5 (1925). E. J. C.

Chili saltpetrer. EMILIO PAPASGLI. *Rass. min. met. chim.* 58, 77-9 (1925).—A description of the history, character, extent, exploitation and use of Chili NaNO₃. C. C. DAVIS

The preparation of raw potash salts. H. PAPPÉE. *Kali* 19, 174-9, 217-23, 235-41, 275-81, 321-4, 356-64, 402-6 (1925).—The various mech. and chem. methods for the prepn. of raw K salts are reviewed briefly; these include the ordinary wet methods and various processes depending on flotation, electro-magnetic sepn., differential crushing, elutriation and centrifuging. A ternary soly. diagram for KCl in satd. NaCl plus various amts. of MgCl₂ (0-350 g./kg. H₂O) is given. The ordinary method for the extn. and concn. of carnallite is described and the plant and app. are schematically represented. Clarification, i. e., removal of clay slimes, is one of the most serious difficulties. The problem of clarification is discussed quant. The rate of settling of 10 g. of slime from 1 l. of H₂O, mother liquor of sp. gr. 1.2977, end liquor of sp. gr. 1.3043, and dild. end liquor of sp. gr. 1.164, resp., is shown by curves. Expressed as % remaining in suspension at the end of 0.5 hrs. it was, resp., 1.2, 36.3, 41.0, 40.6;

at the end of 7 hrs., 1.0, 4.0, 10.3, 1.4. Data are given for the rate of settling of individual particles of the various constituents of the slimes (*i. e.*, clay, anhydrite, kieserite, NaCl, KCl) in solns. of KCl, MgCl₂ and raw salts. Large-scale expts. on the use of shaker tables and settling systems for the sepn. of slimes and the recovery of K salts from them are described, detailed data being given. Further data and discussion of the foregoing clarification expts. are also given. The raw K salts as mined in 7 districts and as used in 10 plants are classified in great tabular detail as to their compn., physical characteristics, crushability, amt. and characteristics of the slime constituents, etc.

WM B. PLUMMER

Making sodium nitrite by the arc process. H. K. BENSON. *Chem. Met. Eng.* **32**, 803-4 (1925).—See *C. A.* **19**, 2728.

Commercial status of nitrogen fixation. J. M. BRAHAM. *Chem. Met. Eng.* **32**, 862-4 (1925).—A review of com. methods now in use for the fixation of atm. N.

W. H. ROSS

Recent developments in the nitrogen-fixation industry. ANON. *Nature* **115**, 465 (1925).—A review.

F. N. S.

Commercial manufacture of hydrogen and nitrogen by means of reducing gases. Use of large quantities of ammonia. F. LEFEBVRE. *Chimie et Industrie Special No.*, 317-25 (Sept. 1925).—Essentially a description of the process recently developed by the Société l'Oxydrique Française for the production of H₂ (Brit. pats. 199,364; 206,822; 230,046; *C. A.* **18**, 310, 1183, **19**, 3355). The process is also applicable for producing practically pure N by passing air instead of steam over the reduced Fe, the small quantities of SO₂ and CO₂ which may be present being easily eliminated. A. P.-C.

The rate of solution and availability of commercial limes. R. T. HASLAM, F. W. ADAMS and R. H. KEAN. *Ind. Eng. Chem.* **18**, 19-23 (1926).—The rate of soln. (which in general det. the availability of the lime) is shown to depend on the fineness and is directly proportional to the area and to the ultimate soly. of the lime. In an acid forming a sol. lime salt, the increase in rate of soly. over that in H₂O is proportional to the concn. of acid. If an insol. salt is formed the rate of soln. is decreased. For an availability test to be of any value the test must be based on the particular process in which the lime is to be used. Thirteen graphs and 1 drawing of app. are used in the investigation.

J. G. R. ARDAGH

Diatomaceous earth. C. W. DAVIS. *Bur. Mines, Repts. of Investigations No. 2718*, 11 pp. (1925).—The compn., properties, and uses of diatomaceous earth are discussed. Its occurrence and production in Nevada, particularly for miscellaneous uses, in the building trade, as insulation, and for filtration are emphasized. This apparent d. of a dried sample is a measure of the air space and is recommended as a rapid test for valuation as an insulation material. A simple app. giving good results on small samples and its operation are described. A bibliography is appended.

Hydrochloric acid. J. H. EGGLESON. U. S. 1,563,732, Dec. 1. HCl gas and an absorbing liquid such as H₂O and dil. HCl are passed in contact within a tube which is externally cooled, the resulting HCl soln. is sepd. from the unabsorbed gases, a portion of the liquid acid soln. is removed and the remaining portion is dild. and used for further absorption of gaseous HCl in the tube.

Carbon and hydrocyanic acid. R. W. POINDEXTER. U. S. 1,562,914, Nov. 24. Natural gas, kerosene vapor or other hydrocarbon material is mixed with NH₃ and the previously unheated mixt. is introduced into an externally heated zone where it is quickly heated to reacting temp.

Treating sulfide ores and concentrates. M. DEKEYSER. U. S. 1,566,379, Dec. 22. Sulfide ores and concentrates are roasted to produce SO₂, ozone is mixed with the latter and the resulting mixt. is subjected to the action of a catalyst, *e. g.*, oxidized Fe shavings, in order to produce H₂SO₄.

Rotary sulfur burner adapted for use in sulfuric acid manufacture. H. HOWARD. U. S. 1,566,538, Dec. 22.

Apparatus for making sulfuric acid. H. HOWARD. U. S. 1,565,366, Dec. 15. Contact of SO_3 with acid (in making 98% H_2SO_4) or contact of other gases with liquids is effected in an absorption app. in which is placed a contact plate of cast Fe having numerous small perforations and formed in detachable sections.

Removing arsenic from phosphoric acid. O. WOLFE and H. MAEDER. U. S. 1,562,818, Nov. 24. H_3PO_4 contg. As is treated with PH_3 and the pptd. As is sepd.

Composition for removing ammonia from gases. R. P. MASE. U. S. 1,564,433, Dec. 8. Activated charcoal is impregnated with CuSO_4 or other anhyd. Cu salt.

Alkali silicate and aluminate from potash feldspar. S. W. SCOFIELD and J. B. LARUE. U. S. 1,563,875, Dec. 1. Cryst. feldspar is converted into amorphous feldspar, e. g., by calcining at 1350-1400°, and the amorphous feldspar is heated with caustic alkali soln. in a closed vessel; 1 to 2 times the quantity of 90% alkali based on the wt. of the feldspar and an amt. of H_2O substantially equal to that of the feldspar are used. A pressure of about 300 lbs. per sq. in. and a temp. of about 270° are employed and the digestion is continued until insol. materials are solubilized. More H_2O is then added.

Aluminium chloride. L. BURGESS. U. S. 1,566,269, Dec. 22. Material contg. Al silicide is treated with dry HCl gas at a temp. which will produce and vaporize AlCl_3 . The latter is sepd. from FeCl_3 by fractional condensation.

Magnesium chloride. R. C. LORD. U. S. 1,537,479, May 12, 1925. The NH_4Cl mother-liquor of the NH_4 -soda process is treated with dolomitic lime to provide $\text{Ca}(\text{OH})_2$ for quant. reaction with the NH_4Cl in the liquor. Liberated NH_3 is expelled and the remaining slurry treated with CO_2 at a temp. of 60-80° to convert the MgO or $\text{Mg}(\text{OH})_2$ into MgCl_2 . After removal of the pptd. CaCO_3 by filtration, the soln. is evapd. to cause sepn. of NaCl and then further evapd. to obtain solid $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$.

Separating sodium chloride, carbonate and sulfate. C. E. DOUBEAR. U. S. 1,563,613, Dec. 1. A mixt. contg. NaCl , Na_2CO_3 and Na_2SO_4 is leached with a soln. of NaCl , the soln. is sepd. from the undissolved residue and treated with CO_2 and pptd. NaHCO_3 is sepd. The soln. is then treated with NH_3 and pptd. Na_2SO_4 is sepd. NH_3 is distd. off and the final liquor is used for treating a further quantity of the mixed salts.

Calcium nitrate. C. EYER and R. GRIESSBACH. U. S. 1,564,410, Dec. 8. Solid Ca nitrate is prepd. contg. a small proportion of an NH_4 salt such as NH_4NO_3 in mol. distribution, which serves to promote satisfactory solidification.

Potassium carbonate. H. KLOPSTOCK and W. NEUMANN. U. S. 1,562,891, Nov. 24. A KOH soln. is treated with CO_2 in limited quantity so that some KOH will remain in the mother liquor to retain impurities in soln. and pptd. K_2CO_3 is sepd. from the soln.

Arsenates. T. A. MITCHELL and K. TOABE. U. S. 1,564,093, Dec. 1. As_2O_3 is oxidized to arsenic acid in the presence of a concd. soln. of arsenic acid and there is simultaneously added a metallic element such as Pb the arsenate of which is desired. The arsenate is pptd. and the rates of forming arsenic acid and of pptg. the arsenate are regulated so as to maintain a substantially uniform high concn. of the arsenic acid.

Arsenates. H. P. BASSETT. U. S. 1,562,490, Nov. 24. Arsenious compds. such as As_2O_3 in H_2O are treated with a sufficient quantity of a base, e. g., lime, capable of forming a sol. chloride and insol. arsenates to form arsenites of the base. Cl_2 is then added to form arsenates of the base and a chloride of the base, the soln. being maintained acid during the oxidation, and afterward more of the base is added to render the soln. slightly alk. and form insol. arsenates and a sol. chloride.

Separating sodium and potassium hydroxides. T. SUTTER. U. S. 1,562,805, Nov. 24. A soln. contg. both NaOH and KOH is concd. until crystn. occurs at a relatively high temp. (about 60°) and KOH crystals are sepd. at this temp., and, in order to sep. NaOH , the mixt. is dild. so that crystn. occurs only at a lower temp. and NaOH crystals are sepd. at this lower temp.

Reducing sulfates to sulfides. A. H. WHITE. U. S. 1,565,300, Dec. 15. Salts such as Na_2SO_4 or other sulfates are heated with charcoal or other carbonaceous material and a metal oxide such as lime capable of reacting with CO_2 to form a carbonate with evolution of heat at the temp. at which the reduction is carried out and in sufficient quantity to form carbonate with the principal part of the CO_2 evolved in the reduction. The temp. of heating is above 300° but below the temp. at which the carbonate formed dissociates completely (preferably about 600-900° with Na_2SO_4).

Decolorizing and clarifying hydrous magnesium silicates (revivification). M. L. CHAPPELL. U. S. 1,562,868, Nov. 24. A material from the Amargosa Valley, Nevada or other material mainly composed of hydrous Mg silicates, after use for decolorizing

and clarifying petroleum, is revived by treating with a color solvent such as acetone and alc., contg. H_2SO_4 .

Artificial cryolite. H. SPECKETER. U. S. 1,563,536, Dec. 1. In producing artificial cryolite free from Fe from solns. of AlCl_3 or other Al salt contg. Fe, there is added to the soln., while stirring, 9 mol. proportions of HF , at the most, and 3 mol proportions at least of alkali metal chloride, *e. g.*, NaCl , to each mol. proportion of Al_2O_3 and the ppt. thus obtained, in the presence of H_2O , is treated with alkali metal fluoride, *e. g.*, NaF .

Apparatus for making anhydrous metallic chlorides. F. T. WOHLERS. U. S. 1,564,302, Dec. 8. Material such as a metal is fed to a rotary uniformly heated fused silica reaction chamber, together with Cl, and reaction products are led off and condensed.

Coating salts with inert particles. L. A. BUNDS. U. S. 1,562,821, Nov. 24. A ground salt such as CuSO_4 for prepg. *insecticides*, etc. is conveyed in a current of hot air while inter-mixed with talc powder or other inert and more finely ground powder, so that evapn. from the salt particles leaves a salt residue on the particles in which the inert particles are embedded so that they serve to prevent agglomeration.

Hydrogen sulfide. E. BINDSCHEDLER and E. W. RUGELEY. U. S. 1,565,894, Dec. 15. A mixt. of hydrocarbon oil and S is heated and the H_2S thus formed is purified by passing it through charcoal or other material of high absorptive capacity.

Chlorine. E. M. PARTRIDGE and E. W. SCARRITT. U. S. 1,566,040, Dec. 15. A mixt. for generating Cl on contact with moisture comprises a pyrosulfate, a chloride and a permanganate, *e. g.*, $\text{Na}_2\text{S}_2\text{O}_7$, NaCl and KMnO_4 .

Receptacle for liquid oxygen. C. MOTT. U. S. 1,564,612, Dec. 8.

Decolorizing carbon. J. N. A. SAUER. U. S. 1,563,295, Nov. 24. Wood, peat or other carbonaceous material is subjected to a practically continuous heating operation in successive stages. Activating gases are withdrawn and reintroduced into the app. used in a continuous manner.

Activated carbon. G. W. WALLACE. U. S. 1,565,129, Dec. 8. Carbonaceous materials such as peat or wood are subjected in a closed chamber to downwardly moving hot gases coming from a flame burning above the material so that a zone of carbonization travels downwardly, and the carbonized material is cooled without access of air.

Removing suspended impurities from solutions of caliche, borax or other substances by flocculation and filtration. W. BROADBRIDGE, E. EDSEY and W. G. SELLERS. U. S. 1,562,863, Nov. 24. In treated solns. such as those from caliche, a flocculating agent, *e. g.*, oleic acid and wood tar, is added to the soln. to flocculate suspended impurities and facilitate their removal by filtration.

Activating bone char. C. B. DAVIS. U. S. 1,565,911, Dec. 15. Bone char is treated with a C-forming distillate from coal, such as one distg. at $315-450^\circ$, which is nonvolatile at ordinary temps., and passed through a kiln out of contact with air at a temp. of redness but under 1000° , cooled out of contact with air, washed with hot H_2O and then dried and kilned out of contact with air prior to use in refining sugar or for other purpose.

Filtering and decolorizing material from bone. P. L. WOOSTER. U. S. reissue 16,225, Dec. 15. See original pat. No. 1,518,289; C. A. 19, 564.

Synthetic stone resembling sapphire. D. BERTOLINI. U. S. 1,565,777, Dec. 15. Asynthetic stone having the hardness of natural sapphire and the appearance of natural aquamarine comprises Al_2O_3 86 and MgO 14% and a trace each of oxides of Co and V.

Lime putty. D. A. EVANS. U. S. 1,566,587, Dec. 22. In curing "lime putty," H_2O is allowed to settle through the putty mass and excess H_2O is filtered as it discharges from the bottom of the mass.

Hydrating lime. J. P. RICH. U. S. 1,565,107, Dec. 8. A weighed charge of unground lime is added, with agitation, to a calcd. quantity of H_2O to slake all the lime and the agitation is continued while a jet of air is supplied to assist the agitation and sepn. of impurities. The hydrated lime is withdrawn by suction.

Molding cement mixtures or other plastic materials. F. C. RUPPEL. U. S. 1,562,520, Nov. 24. Mech. features adapted for avoiding air bubbles at the surface of the finished articles. The molds are lined with celluloid or similar material.

Sheet-celluloid mold for cement mixtures or other plastic materials. F. C. RUPPEL. U. S. 1,562,519, Nov. 24.

Plant for calcining and clinkering calcite, magnesite, cement mixes and similar materials. R. D. PIKE. U. S. 1,557,873, Oct. 20.

Adhesive. F. G. OKIE. U. S. 1,565,027, Dec. 8. A waterproof adhesive adapted for use with abrasive particles comprises driers 3, white lead 4 and varnish 17 parts.

U. S. 1,565,028 specifies sand paper and similar articles made with the use of waterproof adhesives such as specified above (cf. *C. A.* 19, 565)

Adhesive from corn starch. W. R. LONG. U. S. 1,564,970, Dec. 8. Corn starch is treated with HCl and H₂O and allowed to stand for 24–48 hrs. and then agitated and subjected to heat and to steam pressure.

Porous filling material for acetylene storage tanks. A. B. RAY. U. S. 1,565,328, Dec. 15. Fragments of activated C are bonded with a sugar soln. (which is carbonized on the material) or other bonding agent which does not substantially impair the absorptive capacity of the C.

Rendering paper envelope "windows" or similar transparent material "glareless." C. E. SWETT and W. E. SWIFT. U. S. 1,566,239, Dec. 15. The material is subjected to friction while lubricated, *e. g.*, with a mixt. of a sulfonated oil and H₂O.

Translucent film containing asbestos. N. SULZBERGER. U. S. 1,556,973, Oct. 13. Films adapted for *elec. insulation* or other purposes are made from asbestos and colloidal Al silicate and coated with spar varnish.

Mat finish on asphalted asbestos board or similar materials. W. R. WHITNEY. U. S. 1,566,241, Dec. 15. The surface of the material is decomposed, *e. g.*, by treatment with H₂SO₄.

Phenolic condensation product. C. B. CARTER. U. S. 1,566,823, Dec. 22. (CH₂)₆N₄ and NH₄Cl are produced by reaction between methylene chloride and NH₃. PhOH or other phenolic substance is digested with a soln. of these products (the phenolic compd. is used in excess of equimol proportion with respect to the (CH₂)₆N₄). A fusible sol. resinous product is obtained and sepd. It is adapted for conversion into a hard infusible product.

Phenolic condensation product. C. B. CARTER and A. E. COXE. U. S. 1,566,817, Dec. 22. Phenol itself or other similar phenolic substance and methylal, *e. g.*, dimethyl methylal, are subjected to the action of heat and pressure in the presence of acid and H₂O to obtain artificial resinous products.

Foam stabilization. N. T. EWER. U. S. 1,562,878, Nov. 24. An ext. of chestnut oak bark substantially free from tannin is used for stabilizing fire extinguishing foams (cf. *C. A.* 19, 1177).

Reflocculating china clay or other substances. G. W. ACHESON. U. S. 1,563,713, Dec. 1. China clay, fuller's earth, graphite or other substances in finely divided condition are subjected to successive deflocculation and reflocculation under attrition.

Laminated material for manufacture of self-lubricating gears, etc. L. T. FREDERICK. U. S. 1,564,774, Dec. 8. Woven fabric is arranged in layers and impregnated with a phenolic condensation product capable of hardening under heat and pressure, together with graphite 5%, or less.

Copper linings in vacuum vessels, etc. M. VOLMER. U. S. 1,560,444, Nov. 3. A thin, hardly visible coating of Ag is deposited on the inner surface of a double-walled vacuum vessel or the like. Cu is then deposited over the Ag, the vessel is heated while evacuating the space in the double wall and the Cu coating is simultaneously subjected to the action of H or other reducing gas which prevents oxidation of the Cu.

Cleaning and polishing silver. C. M. HEMEN. U. S. 1,564,786, Dec. 8. A cleansing and lacquer-forming compn. is made from castile soap 4 lbs., oxalic acid 8 oz., NaHCO₃ 12 oz., cottonseed oil or other vegetable oil 1 qt., H₂O 9 gals. and sufficient Paris white substantially to absorb the liquids of the mixt.

Etching. W. A. STRAW. U. S. 1,565,869, Dec. 15. The material to be etched, *e. g.*, glass, is treated with a reagent such as a CaF₂ paste which alone will not cause etching and then immersed in an acid bath, *e. g.*, H₂SO₄, which also alone would not produce the desired etching, so that the 2 reagents together cause the etching.

Impermeabilizing gas-absorbing substances. E. A. G. STREET. U. S. 1,563,673, Dec. 1. Porous electrode substances for batteries, *e. g.*, C electrodes, or other gas-absorbing materials are treated with a concd. colloidal soln. of starch, glue, silica or other suitable nonmetallic substance to form a pectized covering impenetrable to liquids.

Gas-impervious membrane. J. G. E. WRIGHT and V. K. QUACKENBUSH. U. S. 1,532,015, March 31, 1925. The throat lining or bladder of cattle or similar internal animal membranes are prepd. for use in manuf. of bellows, diaphragms, etc., by treatment with glycerol, nigrosine and ethylene glycol, which renders the membrane pliable at low temps., impervious to gas and capable of withstanding wetting without stiffening on drying.

Dental cement. P. W. KRUGER. U. S. 1,562,834, Nov. 24. A Mg cement powder that reacts with guaiacol is mixed with guaiacol and balsam of fir. Cf. *C. A.* 20, 267.

Dental paste for temporary fillings. J. L. SMITH. U. S. 1,564,375, Dec. 8. Beeswax 1, petroleum jelly 3, calcined magnesnia 1, Na baborate 1 and NaHCO_3 2 parts.

Acid-treated cork tips for billiard cues. J. S. PIGA. U. S. 1,532,943, Apr. 7, 1925. Cork tips are treated with acid, *e. g.*, HCl , to effect a uniform slight roughening.

Belt dressing. A. GONDERMAN. U. S. 1,566,592, Dec. 22. Extra heavy lubricating oil 1 qt., rosin 2 lbs. and beeswax 3 oz.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

Operating conditions of Boetius glass furnaces. H. XINGNESSE. *Chaleur et industrie* 6, 536-9(1925).—A discussion of the operation of this type of furnace, showing its disadvantages and giving a heat balance observed in com. operation. A. P.-C.

The rapid production of vitrified clay wares by the combined effects of heat and pressure. A. J. DALE. *Trans. Ceram. Soc. (Eng.)* 24, 262-7(1925).—The application of comparatively low mech. pressures can exert a considerable accelerating effect on the rate of vitrification of certain types of materials at temps. in the region of 1050° . It appears probable that acceleration will be more marked under higher pressure values (up to 4000 lbs. per sq. in.) attainable in a no. of com. briquetting machines. This opens up the possibility of the rapid firing of tiles, building bricks and articles made from surface clays and other materials possessing fairly low refractory values; and of the briquetting, without bond, of certain calcined refractory oxides. H. F. S.

A visit to the osmosis plant at Carlsbad. S. R. HIND. *Trans. Ceram. Soc. (Eng.)* 24, 73-85(1925).—An illustrated description of the works of the Carlsbad Kaolin Electro-Osmosis Co. The process employed does not increase the purity of the product over that obtained by settling alone, but it is a convenient means of removing the clay from suspension. H. F. KRIEGE

The dehydration of kaolinite. Y. V. SAMOILOV. *Trans. Ceram. Soc. (Eng.)* 23, 338-9(1925).—From a study of the heating curves of kaolinite and other Al silicates, S. concludes that in the process of dehydration, kaolinite is decomposed into Al_2SiO_5 and SiO_2 . H. F. S.

The temperature gradient obtained by different rates of heating in unfired bricks, between 15° and 250° . L. S. THEOBALD AND A. T. GREEN. *Trans. Ceram. Soc. (Eng.)* 24, 105-23(1925).—Three com. brands of brick are examd. for their thermal response to heating during the water-smoking period. Temp. readings are taken at the interior and exterior of the brick to det. the thermal cond. and the heat absorbed during the changes produced by heating. The max. rate for the safe heating of green brick to a temp. of 250° is detd. H. F. KRIEGE

An investigation of the effects of load, temperature and time on the deformation of firebrick materials at high temperatures. A. J. DALE. *Trans. Ceram. Soc. (Eng.)* 24, 199-215(1925).—The results of the independent effects of load, temp., and time on the deformation of a typical firebrick at temps. within the subsidence range are: (1) the flow of firebrick material under stress at temps. within the subsidence range is in certain respects qualitatively analogous to the stress-flow relations of "plastic" materials at ordinary temps. (2) For any given temp. within the subsidence range, a yield load range exists; at loads below this yield load range, flow under stress is probably a viscosity effect; at loads immediately above the yield value, flow is presumed to be both viscous and plastic. During this period, the ratio is large compared with the corresponding ratio at stress values below the yield value. (3) The higher the temp. the lower is the value of the yield load. (4) Providing a certain temp. is exceeded, the deformation temp. relation for firebrick material is exponential, *i. e.*, $D = ce^{bt}$, where c and b are consts. for a given loading; below this temp. the deformation-temp. relation is approx. linear, *i. e.*, $D = kT$; the deformation-time relation previously put forward, $D = kt^m$, holds for different load and temp. values under the test conditions. Practical indications have been obtained with regard to the regulation of the rate of rise of temp. during the initial firing of a firebrick setting, the need for accurate limitation of temp. below a prescribed max., dependent on the mat. and on the load to be sustained, the general method of applying a modified Mellor and Moore load-test result to industrial considerations. H. F. S.

An investigation of the changes taking place during the industrial burning of fireclay bricks. A. T. GREEN AND L. S. THEOBALD. *Trans. Ceram. Soc. (Eng.)* 24, 124-58

(1925).—Samples of firebrick were withdrawn from 4 kilns at various stages during the burning and examd. physically. True sp. gr. detns. indicated the changes in the kaolinite mol between 450° and 570°, the polymerization of the Al_2O_3 mol. at about 900°, and defined the vitrification range. The rapid increase in porosity between 600° and 900° is due to the burning out of carbonaceous matter and the change in constitution of the kaolinite. The decrease in porosity above 900° is associated with vitrification. By detg. the loss on ignition the time factor of the dehydration of kaolinite is obtained. Vol. contraction, color changes, formation of "iron" specks and blotches, and the stages of vitrification were observed. Consideration is given the time factor for doing the necessary heat work in the kilns. H. F. KRIEGER

Observations on the elimination of carbonaceous matter from fireclay bricks. L. S. THEOBALD AND A. T. GREEN. *Trans. Ceram. Soc. (Eng.)* **24**, 159-69(1925).—No apparent change took place in half bricks or smaller test pieces on heating them up to 500°, but at 600° oxidation became noticeable. Complete elimination at this temp. could be effected by prolonged heating. If 650-900 temps were used there formed a bluish white ring surrounding the black core. This ring later gave place to a yellow area, especially in a deficiency of air. If the carbonaceous matter was burned out below 600° no yellow core formed but a uniform salmon pink color developed. The elimination decidedly affects the true sp. gr. of the brick. H. F. K

Some fallacies to be avoided in the standardization of any method of testing the load-bearing capacities of refractories, at high temperatures, and a suggested method for standardization. A. J. DALE. *Trans. Ceram. Soc. (Eng.)* **24**, 216-27(1925).—Methods which involve rapid application of load are unsuitable as standardized methods of testing the load-bearing capacities of refractories at high temps; methods which require the penetration of loaded rods into the material also are of questionable value. Any method of testing the load-bearing capacity of firebrick at high temp. is to be avoided, from the standardization viewpoint, if it involves merely one detn. of the amt. of subsidence at a fixed temp. and under a fixed load. The results from such a test will not necessarily place the materials in order of merit from the practical load-bearing point of view. Any high-temp. load-test on fireclay products which involves merely the recording of the temp. (or cone) at which collapse takes place, under a fixed load and const. rate of rise of temp., may also yield anomalous results. H. F. S.

Fractional fusion of refractories. R. HUSTIN. *Chimie et industrie* **14**, 691-2 (1925).—On changing the lining of a reheating furnace from ordinary grade of brick to a special grade, the life of the lining was increased from 1 week to 4 weeks. The special bricks fused partially during the first week, after which fusion stopped and the bricks gave good service. Analysis of the unaffected and of the fused portions of the bricks gave: SiO_2 78.80, 56.30, Al_2O_3 18.28, 31.53; Fe_2O_3 2.47, 8.97; CaO 0.56, 2.17; MgO 0.26, 0.62%, resp. The change in compn. is due to the loss of 51% (on the original wt. of the brick) of free SiO_2 , which formed fusible silicates with fluxing agents introduced with the C. The resultant increase in the Al_2O_3 content of the outside of the brick increased its refractoriness, resulting in increased life of the lining. Similar reactions might occur in the absence of external fluxing agents by reaction of the free SiO_2 with the fluxing agents in the brick itself. A. PAPINEAU-COUTURE

The relation between under-load refractoriness, ordinary refractoriness, and composition, physical and chemical, of refractory materials. II. Firebricks. A. J. DALE. *Trans. Ceram. Soc. (Eng.)* **24**, 170-98(1925); cf. C. A. **19**, 3358.—The information obtained from the ordinary refractory test is not a reliable criterion as to the behavior of refractory material of the aluminosilicate type under load conditions at elevated temps.; nor can the cone or temp. at which complete failure under load occurs be accepted as an infallible indication of rigidity at lower temps. Under the test conditions of this work, all the firebrick materials examd. exhibit a diminution in the coeff. of thermal expansion under a load of 50 lbs. per sq. in. at temps. below 1300°; in certain cases as low as 1000°, but with the majority of materials 1200° appears to be a crit. point in this respect. Complete failure under load at high temps. is preceded by deformation occurring during a more or less extended temp. range. The rate and amt. of deformation (d) under load at 1350° is related to the time (t) of heat treatment at this temp. by the equation $d = (t/a)^m$; with the units adopted herein, a value of m greater than unity is an indication that ultimate failure under load results chiefly from the effect of temp. on the property of cohesion; a low value of m accompanies deformation with marked softening or diminished internal friction of the brick substances. With 3 exptl. clay-grog mixts., the value of m was lower with the highly grogged bricks than with the bricks of lower grog content or the straight clay bricks.

A classification of firebrick materials based on their load behavior at high temps. has been suggested. H. F. S.

Furnace ash as a refractory material. H. E. WEIGHTMAN. *Power* **62**, 557-60 (1925).—The materials used in refractories are briefly described. Causes of refractory failure are given. A method is described by which a suitable refractory for patching may be prep'd. from coal ash. D. B. DILL

The influence of oxidizing and reducing atmospheres on refractory materials. I. Experiments with a cone mixture containing added amounts of a ferruginous material. A. E. J. VICKERS AND L. S. THEOBALD. *Trans. Ceram. Soc. (Eng.)* **24**, 86-97, 98-104 (1925). By using a Hirsch elec. furnace, the effect of different atms. on a cone mixt. contg. 0.25% Thiviers earth has been det'd. The softening temp. of the test pieces increased in O_2 and in air compared to the values obtained in N_2 as standard. SO_2 and CO_2 seem to act as reducing gases. H_2 acts strongly as a reducing gas, the softening temp. of the test piece with the highest Fe content being lowered some 250° . Variations in the color were noted with the different atms. With the same app. it was found that the reducing action of CO lowered the softening point 170° for the cones contg. 2.50% Fe_2O_3 and 0.085% FeO as Thiviers earth. With water vapor more striking results were observed than with H_2 . This greater activity is explained by the ionization of the H_2O vapor under the conditions maintained. H. F. KRIEGER

The heat-insulating efficiencies of some diatomaceous earth products and slag wool. A. T. GREEN AND H. EDWARDS. *Trans. Ceram. Soc. (Eng.)* **24**, 228-39 (1925).—There is a definite porosity (apparent sp. gr., consistency or packing density) for materials of the same constitution, which gives a max. insulating efficiency. Pure diatomaceous earth packed so as to possess an apparent sp. gr. of 0.34 has a greater insulating effect than the same material loosely packed (apparent sp. gr. 0.08), or the same material in slab form possessing an apparent sp. gr. of 0.46. The greatest insulating efficiency of slag wool is obtained with a packing of 10 lbs. per cu. ft. (apparent sp. gr. 0.16) in low temp. practice. H. F. S.

Regenerative furnace for melting glass (U. S. pat. 1,565,370) 1. Reflocculating china-clay (U. S. pat. 1,563,713) 18.

Melting and fining glass. A. L. HARRINGTON. U. S. 1,564,235, Dec. 8. A glass batch is preliminarily fused in a pot, the pot is transferred to an elec. furnace with its molten contents, and the operation including the fining is there completed.

Coating materials with glass. C. E. NELSON. U. S. 1,566,911, Dec. 22. Preheated powd. glass is fed to a blowpipe flame and melted as it passes through the flame and is applied to the surface to be coated.

Increasing the softening temperature of vitreous materials. W. C. SPROESSER. U. S. 1,565,598, Dec. 15. The surface of glass X-ray tubes or similar vitreous material is treated with a soln. of $Na(NH_4)HPO_4$ or other substance which will react to produce a similar effect.

Porcelain articles. E. L. DILLMAN. U. S. 1,566,841, Dec. 22. A mold is formed of plaster of Paris, asbestos and siliceous or other non-fusing compn., an impression is made in the mold, the impression is filled with fusible material such as a porcelain compn. which is adapted for producing dental plates or other articles which are being formed, and, after heating the mold and contents to a temp. which fuses the porcelain and subsequently cooling, the mold is moistened to effect its disintegration.

Dental plates. E. L. DILLMAN. U. S. 1,566,840, Dec. 22. In forming dental plates from fusible material such as porcelain a model is formed of "rare earth" or other material sol. in the presence of moisture, a porcelain plate is formed on the model and fused with it, and the model is then disintegrated and removed by moistening.

Continuous kiln for drying ceramic ware. T. LARSSON. U. S. 1,567,023, Dec. 22.

Refractory brick. R. YOUNGMAN. U. S. 1,564,394, Dec. 8. An unburned refractory brick adapted for building furnace walls comprises calcined magnesite 60, chrome ore 35 and Na silicate 5%.

Refractory material of fused silica. W. A. HARTY. U. S. 1,563,853, Dec. 1. Sand is fused in an elec. furnace beneath a layer of amorphous or cryst. $SiCl_4$.

Enamels and glazes. F. SOMMER AND M. GROTH. U. S. 1,564,907, Dec. 8. Both unburnt clay and burnt clay are used together in enamels and glazes such as may also contain ZrO_2 in order to avoid formation of blisters or bubbles.

Zirconium oxide in enamels, etc. C. J. KINZIE. U. S. 1,562,890, Nov. 24. Crude material contg. ZrO_2 as its principal constituent is mixed with a relatively small quantity

of independently vitrifiable ingredients such as a glass-yielding frit and the charge is heated to decompose and eliminate impurities and produce an enamel opacifier.

Abrasive articles. M. F. BEECHER and M. C. BOOZE. U. S. 1,567,020, Dec. 22. Grains of Al_2O_3 or other abrasive material are mixed with a vitrifiable bonding substance such as a clay and feldspar mixt. in dry condition and the unfired dry mixt. is fired to vitrify the bond. The product is adapted for use as a brick, tile or for grinding wheels.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Note on the chemical analysis of portland cement. G. BAIRE. *Chimie et industrie Special No.*, 331-4 (Sept. 1925).—B gives in great detail a technic for the detn. of SiO_2 , Al_2O_3 , Fe_2O_3 , CaO , MgO , SO_2 , sulfide S and loss on ignition, suitable for artificial portland (not for slag) cement, which gives sufficiently accurate results for ordinary work, in a reasonable time.

A. PAPINEAU-COUTURE

Note on the determination of loss on ignition of cements containing slag. G. BAIRE. *Chimie et industrie Special No.*, 335-6 (Sept. 1925).—Ignition of cement contg. slag causes partial oxidation of CaS to CaSO_4 . In order to obtain correct results SO_2 should be detd. in the cement both before and after ignition and the loss on ignition as found corrected for the O absorbed.

A. PAPINEAU-COUTURE

A new quick-hardening slag cement. P. PRÉVOST. *Chimie et industrie Special No.*, 337-8 (Sept. 1925).—"Louve" brand cement, manufd. by the Société Générale des Chaux et Ciments, has the following av. compn.: combined SiO_2 21.2, sand 12, Al_2O_3 13.8, Fe_2O_3 1.6, CaO 46.3, MgO 2.1, SO_2 0.9, undetd. 9.6%; fineness, 1% held on a 75-mesh (per in.) sieve, 10% held on a 175-mesh sieve; apparent d. 0.880, deformation at 100° 1 mm. Setting begins in about 5 hrs. and is complete in 8-15 hrs. Results of tests are given showing it to have considerably higher tensile and crushing strengths after 1, 2, 7, 28 and 90 days than slag and artificial portland cements meeting the specifications of the City of Paris. The process of manuf. is not disclosed. A. P.-C.

Action of sodium and magnesium sulfates on calcium aluminates. G. R. SHELTON. *Ind. Eng. Chem.* 17, 1267-70 (1925).—Previous work on the action of Na_2SO_4 and MgSO_4 solns. on port cement (C. A. 19, 2117) was continued by studying the action of the same solns. on $\text{CaO} \cdot \text{Al}_2\text{O}_3$, 5 $\text{CaO} \cdot 3\text{Al}_2\text{O}_3$ and 3 $\text{CaO} \cdot 5\text{Al}_2\text{O}_3$, both before and after hydration with H_2O . The hydration product of each was a mixt. of hydrated 3 $\text{CaO} \cdot \text{Al}_2\text{O}_3$ and amorphous substance. The amt. of the latter and the time for complete hydration both increased with the Al_2O_3 content of the aluminate. *Sulfoaluminate crystals* were formed from all 3 Ca aluminates, cryst. and hydrated, with Na_2SO_4 of all concns. and with MgSO_4 below 0.1 M concn., the largest quantities being formed from hydrated aluminates and dil. solns. Their max. and min. values of n were 1.463 ± 0.003 and 1.461 ± 0.003 , resp. Above 0.1 M concn., the only cryst. product from MgSO_4 was gypsum. Layers of gel, most abundant with MgSO_4 , surrounded the cryst. aluminate grains and ultimately protected them from further action. This protection was greatest with concd. solns. and with the aluminates of max. Al_2O_3 content. With cryst. aluminates and very dil. solns., hydrated 3 $\text{CaO} \cdot \text{Al}_2\text{O}_3$ crystals formed only momentarily or not at all, in contrast to the behavior of cryst. 3 $\text{CaO} \cdot \text{Al}_2\text{O}_3$ in such solns., which grew large and remained unchanged.

C. C. DAVIS

Relation between water permeability and water absorption of concrete. E. VALD ANDERSON. *Ind. Eng. Chem.* 18, 17-8 (1926).—No direct relation was found. Direct detn. of permeability is recommended.

RAYMOND WILSON

Modern roads and the chemical problems which they bring up. LÉON BALLAN. *Chimie et industrie Special No.*, 346-59 (Sept. 1925).—General discussion of the use of hydraulic cements, bitumens, and coal-tar products in road-making.

A. P.-C.

Conservation of mine timber in North American mining practice. ROBERT NOWOTNY. *Braunkohle* 24, 760-2 (1925).—A brief discussion of American methods of preservation of mine timbers.

WM. B. PLUMMER

Relation of moisture content of wood to its decay. W. H. SNELL, N. O. HOWARD AND M. U. LAMB. *Science* 62, 377-9 (1925); cf. C. A. 15, 3744.—The purposes of this study were: to det. the relation of decay of certain light woods to the air-moisture balance; to compare the air-moisture requirements of *Lenzites sepiaria*, *L. trabea*, *Trameles serialis*, *T. carnea*, *Fomes roseus* and *Leninus lepidus*; and to correlate the matters of moisture, air content and decay to the sp. gr. of the wood decayed. The max. moisture content at which decay can take place in common com. woods is 190

to 200%. Beyond this point there is not enough air to support the growth of the fungi. In general the moisture content favoring a max. decay will vary inversely as the sp. gr. It is thought that heavy woods resist decay because of the small air content and not from the presence of tannin or resins. L. W. RIGGS

Thermal decomposition of sulfates and some reactions of CaSO_4 (MARCHAL) 6. Rubber composition [as wall covering] (U. S. pat. 1,566,247) 30. Plant for calcining cement mixes (U. S. pat. 1,557,873) 18.

TAYLOR, FREDERICK W., THOMPSON, SANFORD E. AND SMULSKI, EDWARD. **Concrete, Plain and Reinforced**—Vol. I. 4th ed. rewritten. New York: John Wiley & Sons, Inc. 969 pp. \$8.

Cement. C. LEONARDT. U. S. 1,563,755, Dec. 1. In prepg. a plastic waterproof cement, limestone or other material contg. CaCO_3 is treated with HCl, asphalt and crude petroleum oil or other oleaginous substance is added, and the resulting mixt is added to ordinary port. cement.

Cement mixtures. K. WINKLER. U. S. 1,565,839, Dec. 15. Cement mixts. are gaged with a soln. of CaCl_2 of about 23° Bé. to which 3% or less of powd. Mn oxide and Cr oxide has been added. This mixt. serves to produce a quick setting highly waterproof product.

Refractory cement. F. C. F. LE COUITRE. U. S. 1,565,472, Dec. 15. Finely powd. Zr ore is mixed with org. and inorg. binders such as dextrin 0.4 and H_3BO_3 0.2% and with about 30% of substantially pure ZrO_2 .

Flexible cement composition. O. OLESEN. U. S. 1,566,917, Dec. 22. A mixt. adapted for packing in air-tight containers comprises sand 8, port. cement 4, Ca soap 4 and Zn soap 1 part.

Waterproof portland cement. C. N. MILLER. U. S. 1,566,498, Dec. 22. A mixt. of β -naphthol and a non-volatile oil such as a petroleum oil is used for waterproofing cement at the time of grinding the clinker.

Gypsum from anhydrite. M. FARNSWORTH. U. S. 1,566,186, Dec. 15. Anhydrite is ground to such a size that the largest particles are between 18 and 135 microns and the av. particle size is between 7 and 30 microns and the ground material is hydrated.

Bituminous paving mixture. G. COBB. U. S. 1,565,258, Dec. 15. Bitumen 3.5–5% is mixed with crushed rock aggregate passing a No. 200 mesh sieve not over 5%, passing a No. 10 mesh sieve 5–15%, passing a $\frac{1}{4}$ in. screen 15–25%, passing a $\frac{1}{2}$ in. screen 20–35% and passing a $\frac{3}{4}$ in. screen 20–40%.

Bituminous soap for binding and waterproofing. L. S. VAN WESTRUM. U. S. 1,565,125, Dec. 8. A product adapted for use as a binder or waterproofing agent in paving, building materials, etc., is prepd. by mixing, while hot, 30–50 parts asphalt, 3–8 parts resin, 3–8 parts linseed oil and 5–50 parts NaOH soln. until sapon. is complete.

Wall-board composition. J. W. OELHAFEN. U. S. 1,564,706, Dec. 8. Sawdust 89, molasses 1, Na silicate 5 and whiting 5%.

Preserving wood. C. T. HENDERSON AND L. ROSENSTEIN. U. S. 1,565,503, Dec. 15. An emulsion for preserving wood is formed of about 85% of an asphalt base mineral oil or a similar H_2O -repellent liquid, mixed with about 10% of a toxic inorg. salt such as ZnCl_2 or NaF in aq. soln. and with about 5% of an org. emulsifying agent, *e. g.*, sulfonic acids.

Grained finish on wood produced by charring. J. SHULER. U. S. 1,566,985, Dec. 22. Cypress, pine, oak or other wood is treated with a soln. (such as an aq. soln. of HCl and KNO_3) which will protect the softer portions against charring to a greater extent than it will protect the harder portions and the surface is then subjected to charring and rubbing.

21—FUELS, GAS, TAR AND COKE

The present status of coal carbonization in Germany. G. CANTIENY. *Combustion* 13, 209-13(1925).—See *C. A.* 19, 2873.

J. F. BYRNE

Influence of the ash constituents in the carbonization and gasification of coal, with special reference to nitrogen and sulfur. I. Preparation and preliminary examination of special cokes. C. B. MARSON AND J. W. COBB. *Gas J.* 171, 39-45(1925).—M. and C. prepd. special impure cokes by the addn. of SiO_2 , Al_2O_3 , CaO , CaCO_3 , Fe_2O_3 , Na_2CO_3 and NaOH to a coal contg. less than 1% ash, at the two temps. of 500° and 800° and compared the behavior of such cokes with each other and with the pure cokes. The heating period for coke prepn. was 5 to 6 hrs. The pure coke was spongy and swollen. The Fe_2O_3 coke was smaller in bulk, compact, finely porous, and much more resistant to crushing than the others; its sp. gr. apart from added oxide was no higher than that of the pure coke. NaOH destroyed the coking quality, while Na_2CO_3 gave a compact, finely porous coke particularly resistant to crushing. The effects of Al_2O_3 and SiO_2 were not noticeable. Fe_2O_3 , CaO and CaCO_3 reduce the N left in the coke prepd. at 800° while NaOH and Na_2CO_3 increase it. These effects are not noticeable in the cokes prepd. at 500°. The N content was lower in the pure coke prepd. at 800° than in that prepd. at 500°. Fe_2O_3 , CaO , NaOH and Na_2CO_3 in the descending order named increase the S content of the 800° cokes; Fe_2O_3 and CaO are also effective to a less extent at 500°. The S content of the 800° coke was less than that of the 500° coke. An historical review and the analytical methods used are given.

A. E. G.

Investigations on the low-temperature carbonization of coal. J. SAINTE-CLAIRE DEVILLE. *Chimie et industrie Special No.*, 164-72(Sept. 1925).—Description of the results of low-temp. carbonization tests carried out by the Sarre Mines, with a discussion of the possibilities of this process from an economic standpoint. On the whole the results reported do not bring out anything very new; but D. draws attention to the advisability of drying the coal before carbonization (e. g., by the waste gases from the retort), and to the fact that with very shaly coals the output from the retort is not greatly affected owing to the higher d. and lower sp. heat of the shale.

A. P.-C.

Low-temperature carbonization of lignites and bituminous shales. CHARLES BERTHELOT. *Chimie et industrie Special No.*, 174-80(Sept. 1925).—From a discussion of the mechanism of distn. and requirements for optimum conditions of low-temp. carbonization, B. concludes that the Salerni retort is the one best adapted for the latter process. With a small (100 kg.) intermittent retort, he obtained the following tar yields from various fuels: lignites 44-165 kg. per ton; bituminous coal 30-137 kg. per ton; bituminous shale 56-280 kg. per ton, all on the dry basis. The possible field of application of the process is discussed.

A. PAPINEAU-COUTURE

The carbonization of non-coking coals with particular reference to lignite. W. W. ODELL. *Proc. Am. Gas Assoc.* 1925, (advance copy) 7 pp.—A review and discussion of the work of the Bureau of Mines and the Lignite Utilization Board of Canada, describing in particular the construction and operation of the carbonizing app. developed by the latter workers.

WM. B. PLUMMER

The mechanism of the carbonization of coal in the by-product coke oven. N. A. ROSS. *Gas World* 83, 12-4(1925).—R. considers the carbonization theories of Illing-

worth, Beilby and Foxwell, makes comparisons, draws conclusions and gives his own theory. Before the plastic stage H_2O is driven off, β - and γ -comps. are formed by thermal decompn. of the coal, β - and γ -comps., commence to decompose and cell formation commences. During the plastic stage β - and γ -comps. decompose completely, the resultant gas extrudes molten γ -comps., plasticity is set up, and coke structure formed. Toward close of this stage the coke hardens. After the plastic stage the thick soft cell walls are further broken down and the remaining volatile matter is evolved with formation of the microstructure. A. E. GALLOWAY

Industrial furnaces. W. TRINKS. *Mech. Eng.* **47**, 1065-71(1925).—A comparison of boiler and industrial furnaces, and a discussion of: fuels for industrial furnaces, furnace efficiencies, automatic temp. control, means of detg. furnace sizes, and the selection of fuel. A chart indicates the selection of furnaces for industrial heating operations, and numerous types of industrial furnaces are illus. W. H. BOYNTON

Industrial-furnace efficiency. V. J. AZBE. *Mech. Eng.* **47**, 1061-4(1925).—Thermal efficiencies in industrial furnaces are very low. Too little attention has been given to them. Losses are the same as those encountered in boiler furnaces, but, in industrial heating furnaces, are in most cases more difficult to lessen or eliminate. No standard of comparison for industrial heating app. has been established. W. H. B.

Relation of boiler house equipment to plant economy. THEODORE MAYNZ. *Chem. Met. Eng.* **32**, 851-2(1925).—Requirements of a boiler plant may be divided in 3 main items: power, process steam and building heat. Industries using steam in process work should be equipped for the most economical operation. Accessory equipment should include: stop and non-return valves, soot blowers, flowmeters and CO_2 recorders, or boiler meters equipped with the above app. The transmitting machinery should be properly designed. W. H. BOYNTON

Institution of Gas Engineers' annual Presidential address. J. F. BELL. *Gas J.* **170**, 863-9(1925).—A review of the Institution's activities and of the progress of the industry. A statistical comparison of gas, elec., and coal consuming appliances is made. Economic phases are discussed. Thermal values of gas coal and coke, thermal efficiencies of horizontal and vertical retorts, blue water and carburetted water gas, and low-temp. carbonization are given. A. E. GALLOWAY

Gas tariffs. VAUPEL. *Gas u. Wasserfuch* **68**, 707-11(1925).—Rate systems in use in several German cities for domestic and industrial gas consumers are described and discussed. WM. B. PLUMMER

The economics of gas production on the thermal basis. GEORGE EVETTS. *Gas J.* **170**, 813-52(1925).—An extended discussion of economic phases and a strong argument for the manuf. and sale of gas on the thermal basis. The vol. of the gas must be considered in conjunction with the heat units. The following factors must influence the choice of the declared calorific value: (1) the satisfaction of the consumer; (2) the class of coal available; (3) relative values of coal, oil and residual products; (4) and (5) the capacity and type of existing plant; (6) the capacity of the distribution system; (7) latest development in mfg. processes; (8) operating costs; (9) capital costs and rate of interest on money. A. E. GALLOWAY

The manufacture of blue water gas. A. PARKER. *Nature* **115**, 501-2(1925).—A review. F. N. S.

Water-cooled water gas generator with automatic ash removal at the Rotterdam gas works. M. C. SISSINGH. *Gas u. Wasserfuch* **68**, 734-6(1925).—The generator wall at the fire zone is formed by an annular boiler, no refractory being used; the internal diam. of the generator being 2.6 m., the space between the walls of the annular boiler is 0.5 m., it being of welded construction from ordinary boiler plate. Above the fire zone the generator wall is of ordinary refractory construction. In the test described the fuel coke contained 11.6% ash and 87.3% C + S, the slack discharged by the automatic rotary grate contg. 48.8% ash, 47.5% C, 3.7% H_2O . The gas yield was 1 cu. m./0.53 kg. coke (net), its heating value 2556 kg. cal./cu. m., steam used per cu. m. gas 0.386 kg., % steam undecomposed 38.3. The generator wall boiler furnished 84.5% of the total steam required. Considerable savings in operating costs, especially labor, are indicated. WM. B. PLUMMER

Report of sub-committee on tests on and developments of oil sprays for water gas machines. J. H. WOLFE. *Proc. Am. Gas Assoc.* **1925**, (advance copy) 7 pp.—Résumé and discussion of a questionnaire returned by 21 companies. Of these 16 used a mist type spray; further details as to cooling, etc., are given. The rates of input of oil, gal./min./gross sq. ft. carburettor area, were as follows: lowest min. rate 0.18; lowest max. rate 0.20; lowest av. 0.23; highest min. 0.88; highest max. 0.96; highest av. 0.94; in 17 out of 27 cases the av. rate was between 0.30 and 0.60. The oil used varied in

gravity from 20 to 40° Bé, with 17 out of 21 using 30–40° oil. The formulas used by the various companies for calcg. oil efficiencies are listed. WM. B. PLUMMER

Report on waste heat and illuminating gas boilers. R. E. KRUGER. *Proc. Am. Gas Assoc.* 1925 (advance copy) 6 pp.—Curves are given for returns earned by such installations for various existing coal costs. The "usual" and the "Rochester" methods of cleaning illuminating gas boilers are described in detail. Some operating data are given. WM. B. PLUMMER

Operating results on vertical retorts (24-hour period) in the Hanover gas works. FRANZ KLEEMAN. *Gas u. Wasserfach* 68, 747–8(1925).—The plant consists of 10 vertical ovens each contg. 6 retorts, the whole being fired by 2 producers and equipped with regenerators. The charge is 5000 kg./retort, and the coking time 24 hrs. The gas yield is 41.9 cu. m./1000 kg. raw coal, its heating value 4625 kg. cal./cu. m., its compn. 3.2% CO, 3.2 C₂H₄, 0.8 O₂, 14.2 CO, 11.3 N₂, 14.4 inerts. Coal analysis as charged is 3.2% total H₂O, 8.8 ash, 29.2 volatile matter. Coke fired to producers is 13.8 kg. (dry coke)/100 kg. coal charged. Av. temp. in heating flues is 1235°. WM. B. PLUMMER

Liquid purification of coal gas: its interest for the sending of gas over considerable distance. CH. BERTHELOT. *Chimie et industrie* 14, 663–78(1925).—A discussion of gas-purification processes, describing in detail the process by means of soda ash soln. for the removal of S compds. and recovery of free S, bringing out its advantages over the Fe₂O₃ method and showing that when coke oven gas is used as illuminating gas it is preferable to purify it at the coke-oven plant rather than at the gas distributing station. A. PAPINEAU COUTURE

Experiences with refractories in vertical retorts. T. F. E. RHEAD AND R. E. JEFFERSON. *Gas World* 82, 625–8(1925).—Three graphs are presented showing temps. during heating up. The total expansion was 1.13% of the original height. Examn. of dismantled materials shows very little fusion near the top of most of the combustion flues, fusion in the waste-gas system was not very great until the uptake flue was reached. Conditions in the siliceous and lower firebrick belts were spalled, little changed, slightly fused, or badly fused in places. A. E. GALLOWAY

Use and development of exhaust steam regenerators. R. E. KRUGER. *Proc. Am. Gas Assoc.* 1925 (advance copy) 2 pp.—Steam accumulators for water gas plants as previously described (cf. *C. A.* 19, 2399) are in operation in various plants but reliable data as to their performance are not yet available. WM. B. PLUMMER

Report of sub-committee on developments and results on carburetors, checkered and checkerless. J. H. WOLFE. *Proc. Am. Gas Assoc.* 1925 (advance copy) 15 pp.—Statistical résumé and discussion of replies to a questionnaire on carburetor operation returned by 60 operators. Where conditions have permitted reduction or elimination of the carburetor checker brick, most reports show oil efficiencies equal to or better than av. Mist type oil spray was used by 68% of the companies, solid stream type by 23%, both types by the rest. As temp. control points 67% of the companies used the bottom of the superheater, 12% the top of the superheater, 10% the top and bottom of the superheater, 7% the bottom of the carburetor, while only 1 company used the top of the carburetor. The oil consumption for various B. t. u. values of finished gas has been plotted as an approx. straight line curve (with notation giving fuel, oil and operating characteristics for the various cases). WM. B. PLUMMER

Developments in gas calorimetry. C. V. BOYS. *Gas World* 82, 581–4; *Gas J.* 170, 933–6(1925).—B. discusses developments with his box gas calorimeter and the Boys bell meter and proposes a gasworks method of sampling. A. E. GALLOWAY

Report on oil gas machines. ROBERT LINDSAY. *Proc. Am. Gas Assoc.* 1925 (advance copy) 7 pp.—Plant construction and operating data are given for the single-shell type ("straight shot" method) and the double-shell type (Jones) plants for oil gas manuf. All by-products being disregarded the returns from each process are approx. the same, but if the light oil be recovered and if there be a market for the lamplblack (in the latter process the lamplblack yield is reduced 50% by the use of steam) the straight shot process is estd. to give 10 cents/1000 cu. ft. finished gas greater difference in value of materials and products than does the two-shell process. WM. B. PLUMMER

Report on the Chrisman down run process. H. K. SEELEY AND L. W. SELTZER. *Proc. Am. Gas Assoc.* 1925 (advance copy) 6 pp.—The process is briefly described and results are given from the operation of 3 different plants. The approx. av. of these results is: saving in generator fuel 2–3 lbs./1000 cu. ft.; oil consumption decreased 5% in one case, increased 0.3% in another; make/set/hr. unchanged or increased up to 10%. WM. B. PLUMMER

The wear of internal parts of motors using blast furnace gases. P. MARTINET.

Tech. moderne 17, 765-8(1925).—A discussion of the action of the impurities of the gas and of the lubrication on the various parts of the motor which are subjected to high temps.

A. PAPINEAU-COUTURE

Report of the uncarburetted section of the water gas committee. H. C. BLACKWELL. *Proc. Am. Gas Assoc.* 1925 (advance copy) 3 pp.—Of the 9 companies in the U. S. known to manuf. blue water gas, 8 have furnished descriptions of equipment and operating data, which are tabulated. Of these, 6 produce blue gas for mixing with natural gas, 1 for heating coke ovens, and 1 for standby purposes. WM. B. PLUMMER

Tables for the calculation of pipe lines for compressed gas. J. HOUEL. *J. usines gaz* 49, 337-42(1925).—Eight large scale charts are given which graphically represent the formula $Q = 262,500 [(p_1^2 - p_2^2) D^{5.33} / \delta L]^{0.5}$, where Q is the delivery in cu. m /sec, p_1 and p_2 are the initial and final pressures in kg., resp., D and L the diam. and length of the pipe in m., resp., and δ is the d. of the gas. These charts cover the following ranges: δ , 0.4-0.6; D , 8-220 cm; L , 1-100 km.; Q , 100-50,000 cu. m /hr.; p , up to 15 kg.

WM. B. PLUMMER

Recovery of benzene and of volatile solvents by means of solid absorbents. EDUARD URBAIN. *Chimie et industrie Special No.*, 245-51(Sept., 1925).—Essentially a discussion of the merits of activated charcoal for gasoline and solvent recovery and more particularly of U.'s process which is characterized by the use of indirect heating or cooling of the absorbent, thereby effecting better utilization of the steam injected to recover the solvent and better control of exothermic absorptions.

A. P.-C.

Relation of tar utilization to coal carbonization. S. R. CHURCH. *Chem. Met Eng.* 32, 869-70(1925).—A brief discussion advocating the use of "intermediate" carbonizing conditions, representing a compromise between high and low-temp carbonization, as giving the best combination of high yields and desirable properties of the products

WM. B. PLUMMER

Low-temperature tar yields from Hungarian coals. ERNST LASZLO. *Braunkohle* 24, 733-9(1925).—Available results from com. practice are summarized and results given for lab. expts in Fischer's small rotary assay retort. The data cover a large no. of typical coals; ultimate and proximate analyses are also given

W. B. P.

Composition of some low-temperature tars now being produced on a semi-commercial scale. J. D. DAVIS AND A. E. GALLOWAY. *Proc. Am. Gas Assoc.* 1925 (advance copy) 12 pp.—Exhaustive analytical data are given for 7 low-temp. tars, a coke-oven tar, and a water-gas tar; the low-temp. tars are not identified by the process producing them, but carbonizing conditions and yields are briefly given. The app. used for the lab. tar distns is the standard Bureau of Mines petroleum distn assay app., 300 cc. of tar being distd. in a glass flask to 275° vapor temp. when the distn is continued at 40 mm. pressure to a vapor temp. of 300°; cuts are taken every 25° during both parts of the distn. Tar acids, bases, unsatd. hydrocarbons (sol. in 95% H_2SO_4), aromatic hydrocarbons (sol. in 37 N H_2SO_4), sulfonation residue, and sp. gr. were detd. for each 25° fraction and for the total distillates. The data of the distns. proper are tabulated. Other data given include heating value and ultimate analyses of the tars, tar sp. gr., viscosity, and free-carbon content. The results are discussed from the standpoint of the effect of carbonizing conditions on tar yields and properties.

Carbonization Committee report. A. M. BEEBE. *Proc. Am. Gas Assoc.* 1925 (advance copy) 8 pp.—A general discussion of the present situation and of the program for the coming year, in particular of tests of coke reactivity and of the general characteristics of cokes produced under various com. conditions from the same coals, which tests are being carried out under the auspices of the Am. Gas Assoc. W. P. P

Report of the operators' section. D. W. WILSON. *Proc. Am. Gas Assoc.* 1925 (advance copy) 4 pp.—Further and more detailed discussion of the carbonization tests of the same coal in various plants (cf. preceding abstr.). The coal used is a Pittsburgh Seam gas coal, the plants including 2 intermittent vertical retort installations, 2 of continuous vertical retorts, 1 of horizontal through retorts, and 2 coke ovens. Tests of the cokes are to be carried out jointly by the Mass. Inst. of Tech. and the Bureau of Mines.

WM. B. PLUMMER

Study of cokes from various types of plants using the same coals. R. T. HASLAM. *Proc. Am. Gas Assoc.* (advance copy) 1925, 4 pp.—Description of methods to be used at the Mass. Inst. of Tech. in tests of coke samples from the cooperative carbonization tests (cf. preceding abstr.). Particular emphasis is laid upon the detn. of coke reactivity.

A. C. FIELDNER. *Ibid* 2 pp.—Similar description of the methods to be used in the Bureau of Mines tests of these cokes. WM. B. PLUMMER

The improvement of coke in gas works operation. GERHARD. *Gas u. Wasser-fach* 68, 699-702(1925)—A general discussion of coal mixing, etc. WM. B. PLUMMER

Low-temperature carbonization. S. R. ILLINGWORTH. *Gas World* 82, 608-10 (1925).—A review covering the following: problems and difficulties of low-temp. carbonization; blending and avoidance of swelling; overcoming the difficulty of bulk carbonization; future of the system based on small coal; yields of products; throughput; cooperation between low- and high-temp. methods. A. E. GALLOWAY

The case for low-temperature carbonization in America today. H. W. BROOKS. *Power* 62, 634-8, 680-4(1925).—Low-temp. carbonization is more profitable than by-product coke oven methods on account of lower operating and investment costs, higher oil and richer gas yields and, in certain processes recommended, the delivery of a finely divided, easily ignitable coke which may be more efficiently utilized for power generation. The Middle West is considered the most favorable location for such an installation. Its supply of cheap non-coking bituminous coals can be converted into by-products of local value and a pulverized semi-coke suitable for efficient power production. The economics of high-temp. and of low-temp. methods of carbonization are compared in detail. Also in *Power Plant Eng* 29, 1087, 1139(1925). D. B. DILL

Domestic coke and factors affecting coke formation. J. D. DAVIS AND L. C. KARRICK. *Proc. Am. Gas Assoc.* 1925 (advance copy) 6 pp.—A brief general discussion of the methods and principles of coking. High-temp. carbonization methods applied to coking coals yield the most satisfactory dense domestic fuel. Combinations of briquetting with low-temp. carbonization yield satisfactory domestic fuels, but the com. feasibility of such processes in this country has not yet been demonstrated. WM. B. PLUMMER

Rate of travel of fusion zone in coke ovens. W. P. RYAN. *Proc. Am. Gas Assoc.* 1925 (advance copy) 17 pp.—A general discussion. Further data from tests similar to those of Wilson (*C. A.* 19, 1486) are also reported. The curves for the rate of travel of the fusion zone, or of isotherms below 1100° F., through the charge are in agreement for those calcd. for the rate of heating of a solid slab of const. heat capacity and cond. which is heated by walls of const. temp. This indicates that the thermal characteristics of the coal, plastic coal, and semi-coke are all of the same order of magnitude, and that the heat effects of fusion and thermal decompn. are negligible. As the charge is heated above 1100° F., however, its heat cond. increases suddenly to several times its original value. Since the rate of travel of the fusion zone decreases as its distance from the heating wall increases, until the effect of preheating at the center of the oven causes the rate of travel to increase again as it nears the center, it is evident that the greater the oven width the lower will be the min. rate of travel reached before this increase takes place. Hence since the initial and final (at wall and at oven center) rates of travel are the same regardless of the oven width, it is seen that the wider the oven the lower the av. rate of travel of the fusion zone, *i. e.*, that a given increase in oven width will produce a disproportionately greater increase in the coking time. Treating coal with substances which facilitate breaking or mining. R. LESSING. U. S. 1,532,826, Apr. 7, 1925. Breaking up and mining of coal is facilitated by treating the coal *in situ* with 0.1% of SO₂, pyridine, aniline, quinoline or other substance which weakens the union between the constituents of the coal.

Coal briquets. E. EDSEER and W. H. BEASLEY. U. S. 1,562,876, Nov. 24. Finely divided coal is agitated as an acidified pulp with a frothing agent such as cresol and kerosene and with a pitch or tar or a similar substance having normally no affinity for the coal particles and adapted to serve as a binding medium, to effect agglomeration.

High-pressure hydrogenation of heavy mineral oils, coal distillates and slack. INTERNATIONALE BERGIN COMPAGNIE VOOR OLIE- EN KOLEN-CHEMIE. Dutch 13,594, Oct. 15, 1925. The materials are heated (300–500°) in H₂ at 50–100 atm. with the addition of about 5% alkali metal as catalyzer for the desulfuration and cracking. Porous substances, fuller's earth, charcoal, coke ash may be added to the mixt. for further refining of the product.

Fuel for internal-combustion engines. J. F. P. DE LA RIBOISIÈRE. U. S. 1,534,573, Apr. 21, 1925. A hydrocarbon fuel contg. a considerable proportion of hydrocarbons b. above 160°, and which may also contain alc. and ether, is admixed with phenyl compds. such as those of Se, Te, Th, Tl, U, W, Ti, Bi, V, or Al, dibenzyl salicylate, benzyl amines, benzyl anilines, benzyl alcs., benzylhydroxy amines or similar compds. in small quantity to increase the power developed from the fuel and decrease the consumption of fuel.

Fuel briquets. A. D. PARKER. U. S. 1,564,890, Dec. 8. Starch and borax are heated in H₂O and emulsified with hot asphalt to form a binder for culm or other material to be briquetted.

Briquetting fuels. R. KATTNER. U. S. 1,562,564, Nov. 24. Coal fines or other fuel material is mixed with MgCl₂ and MgO is then added and the mixt. is molded and pressed, H₂O also being added if necessary.

Gaseous fuel. J. HARRIS. U. S. 1,565,933, Dec. 15. A gas adapted for use in cutting metals comprises natural gas mixed with about 2½% or more of ether vapor. U. S. 1,565,934 specifies CO instead of natural gas and U. S. 1,565,935 specifies casing head gas with about 5% of ether vapor.

Fuel spreader for gas generators, etc. O. B. EVANS. U. S. 1,564,546, Dec. 8.

Phenols from gas liquors. L. W. HEFFNER and W. TIDY. U. S. 1,566,795, Dec. 22. Liquors contg. small quantities of phenols are heated to 98° or higher in the presence of sufficient NH₃ to drive off the phenol as phenolate. U. S. 1,566,796 specifies a similar distn. of ammoniacal liquors contg. phenols.

Gasoline from "wet" natural gas. H. A. MOSSOR. U. S. 1,565,749, Dec. 15. Wet natural gas is first compressed and cooled to remove as liquid a portion of its gasoline content. The compressed gas is then subjected to the action of an absorbing menstruum, the latter is sepd. from the denuded gas and the pressure on the menstruum is reduced to liberate its gasoline content as vapor. The vapor thus liberated is mixed with wet natural gas before the latter is subjected to the compression and cooling step.

Catalytic oil-gas retort apparatus. L. BLANCHET. U. S. 1,565,409, Dec. 15.

Open-hearth furnace adapted for burning tar, oil, coal or gas. W. DYRSSEN. U. S. 1,564,330, Dec. 8.

Composition for removing carbon deposits from internal-combustion engines. J. BIRD. U. S. 1,565,779, Dec. 15. Tablets are formed from (NH₄)₂CO₃ and C₁₀H₈.

Calcining petroleum coke or similar materials. A. S. WALDEN. U. S. 1,564,730, Dec. 8. A stream of the material is moved through zones of successively increasing temp., e. g., in a horizontal inclined rotary kiln, the temp. at which the solid residue begins to undergo oxidation being that of an intermediate zone. The evolved gases are burned with a deficiency of O in the zones hotter than the intermediate zone and the residual gases are subsequently completely burned in the zones of lower temp.

Coking pitch or similar materials. F. W. SPERR, JR. U. S. 1,563,595, Dec. 1. In producing a low-ash coke from materials such as pitch a portion of the material is heated to expel part of the volatile matter and produce a semi-coke. The latter is mixed with additional pitch and the mixt. subjected to a coking temp.

Oil for Canada from her tar sands. R. B. DAY. *Oil & Gas J.* **24**, No. 14, 21, 130 (1925).—A description of the Athabaska Region in Alberta is given. Methods suggested for the utilization of the bituminous sands of the Athabaska Region include the sepn. of the oil and sand by extn. with solvents, hot water, or mud; mixt. of the sands as they exist with dry sand or crushed limestone for use as paving material, the destructive distn. in closed retorts. The third method is most feasible since by cracking the heavy oil a 25% gasoline and 30% kerosene yield will be obtained with a residual oil which may be further cracked.

M. B. HART

Conservation and treatment of crude oil recovered from sand formations. M. E. LAYNE. *Oil Age* **22**, No. 6, 23(1925).—In the sepn. and recovery of gas and oil encountered in deep wells in loose sand under high pressure, controlling and balancing of this pressure are necessary. Great care should be taken that the clay-treated circulation water is free from all trash. The clay fills the openings in the sand and it can only be removed by thorough washing outside of the screen. But if the openings in the sand are partially filled with trash, this refuse will be drawn into the screen openings, clogging a large part of the same when the bringing in of the well is undertaken. It is important thoroughly to wash the outside of the screen and remove the clay wall from the sand back of the screen before the pressure is removed from the inside of the screen, by washing.

M. B. HART

Changes undergone by mineral oils in colloidal systems. F. EVERS. *Z. angew. Chem.* **38**, 659-62(1925).—Although an exhaustive analysis of the changes undergone by mineral oils in the capillaries of the materials (*i. e.*, in colloidal systems) from which transformers and switches are made, cannot now be made on account of the lack of information, E. is convinced that it is these changes that cause the deterioration of transformer and switch oils in service. The high concns. of O_2 and of H_2O in the oil in the capillaries increase the rates at which acidic substances that by dehydration and condensation give rise to sludge are formed. Analyses of a very old sample of oil from a transformer are given; the sample differs radically from gilsonite, which also is sol. in C_6H_6 . The part of the oil that is insol. in petroleum ether has the following elementary analysis: C 78.8, H 7.1 and O 14.1. The removal of acidic substances and "tar" from a used transformer oil is much less complete when silica gel is used than when silicates are used. The removal of acid is better when a given proportion of the silicate is used in successive portions rather than as a single portion. W. F. F.

Specific heats, heats of vaporization and critical temperatures of California petroleum oils. E. H. ZEITFUCHS. *Ind. Eng. Chem.* **18**, 79-82(1926).—Sp. heats were detd. by heating the oils in a sealed capsule and dropping the capsule into H_2O contained in a Dewar flask. Errors caused by differences between the sp. heat of vapor and liquid and by the heat of condensation of vapor were minimized by nearly filling the capsule with oil. Oils were heated to 371.1° as a max. A table and graphs show the heat of liquid (above 25°) vs. temperature. Other tables and graphs show calcd. sp. heats (true) as functions of the sp. gr. Critical temps. of petroleum ether, gasoline, crude naphtha, crude kerosene, gas oil and mineral seal distillate were detd. by heating samples in a Pyrex tube (2 mm. bore \times 8 mm. outside diam.). Heats of vaporization were calcd. at the mean b. p. by means of Trouton's rule. Curves showing the relation between latent heat of evapn. and temp. were plotted for pure hydrocarbons and the slopes of the tangents at the b. p. were found to be nearly equal. Curves for the oils were then drawn tangent to a line at the mean b. p. parallel to the tangents of the curves

for pure hydrocarbons and of the general shape of these curves. The curves were extended to the critical temp., where the latent heat of evapn. has the value, 0. The data are suitable for use in engineering calcs.

W. F. FARAGHER

Sulfuric acid absorption and iodine values of various petroleum products and cracked distillates obtained therefrom. J. C. MORRELL and GUSTAV EGLOFF. *Ind. Eng. Chem.* **17**, 1259-61 (1925).—Absorptions were detd. by shaking 5 cc. of oil with 4 cc. of H_2SO_4 (1.84 sp. gr.), in a 10-cc. graduated cylinder. After centrifuging, the vol. of the undissolved oil was read. Upon comparing charging stocks and crude-petroleum distillates made from them in a commercial Dubb's unit, the absorptions are greater for the stocks than for the corresponding distillates. With Hanus soln., the I nos. of oils are found to decrease by increasing the wt. of oil in a fixed vol. of soln., or by decreasing the vol. of soln. for a given wt. of oil. Nevertheless, for a given oil, const. I nos. are obtained if the ratio of wt. of oil to vol. of Hanus soln. is kept const.

W. F. FARAGHER

Thermal expansion of California petroleum oil. E. H. ZEIFFUCHS. *Ind. Eng. Chem.* **17**, 1280-3 (1925).—Refinery products from typical California crude petroleum were investigated. Glass pycnometers were used at temps. up to 200° and a steel pycnometer was used up to 410° . Sources of error are discussed. No single equation expresses the relation between sp. vol. and temp. over the whole range. California products below 25°A.P.I. have a slightly lower rate of expansion, and those above 25° a greater rate than the tables in Bur. Standards, *Tech. Paper No. 77* show (cf. *C. A.* **10**, 2983).

W. F. FARAGHER

Linton process attracts attention. C. E. KERN. *Oil & Gas J.* **24**, No. 8, 146 (1925).—The Linton process for the production of gasoline and lubricating oils is explained as being a conversion not a cracking process which converts heavy residual into light hydrocarbons, without pressure and without volumetric loss. This is accomplished by gradually pre-heating crude oil under certain conditions and letting it run in a thin film over mildly heated surfaces in a specially constructed apparatus which forms a motor spirit concentrate (or anti-knock element called canary concentrate) and a straight motor fuel. Further, a high-class lubricant, having characteristics similar to those of castor oil, is made from the topped crude.

M. B. HART

Little petroleum formed by true oil shales in nature. F. M. VAN TUYLAND and C. O. BLACKBURN. *Oil & Gas J.* **24**, No. 10, 188 (1925).—Expts. conducted to test the hypothesis that oil exists as such in shale indicate that important quantities of petroleum have not been formed from true oil shales except possibly in the vicinity of igneous intrusions where the temps. have been unusually high. Kerogen and petroleum are not genetically related but represent different end products of transformation of org. debris, probably because of differences in bacterial action, at the time of deposition. Cylinders of oil shale were caused to flow in specially constructed steel spools under pressure. Detn. of the free oil content before and after flowage indicated that no free oil was produced at elevated temps.

M. B. HART

New process for bleaching gasolines obtained by cracking or by catalysis. A. MAILHE. *Compt. rend.* **181**, 668-9 (1925).—Gasoline contg. diolefins and other easily polymerized hydrocarbons can be refined and decolorized by boiling with metallic chlorides (especially SnCl_2), or by passing the vapors over the chlorides at about 200° . The treated gasoline is washed with NaOH and with H_2O and is rectified. The SnCl_2 can be used repeatedly and when its activity decreases it is easily regenerated by treatment with HCl . The process is also applicable to crude benzenes.

A. PAPINEAU-COUTURE

Expansion methods of refining. R. K. COLLINS. *Ref. & Nat. Gasoline Mfr.* **4**, No. 8, 23 (1925).—The Collins Expansion Process used by the Sunrise Laboratories Corporation is either a batch, semi-continuous or continuous process in which the initial material is charged either direct or through a heat exchanger to the shell type horizontal stills. When recoverable straight-run gasoline is present the first stills are used for skimming, the fourth, fifth and sixth stills being equipped with Collins Expanders. Vapors from No. 4 still pass into No. 1 expander where a thermo mech. treatment has the effect of rearranging their at. and mol. structure to produce a larger yield of gasoline, naphtha or kerosene as desired. Bottoms from No. 4 still pass into No. 5 still and are treated in No. 2 expander, etc. The thermo mech. adjustment in each expander differs, producing a common product. The product is passed through dephlegmators and expanders, and is then condensed and treated as usual.

M. B. HART

Re-running eliminated in skimming plant. G. TRIPLETT. *Refiner & Nat. Gasoline Mfr.* **4**, No. 7, 32, 34, 36 (1925).—Re-running has been eliminated by cutting back the stream from the tower into the still while it is still hot. The Christman reflux tower used at the Caddo Central Oil and Refining Co. is a horizontal tower equipped

with pans and perforated baffle plates. Each pan has a pipe from the center leading from the tower. If any stream from a tower comes over in undesirable condition it can be turned back into the stills and re-run while hot. Still further saving is made possible by preheating the crude in a shell containing a manifold coil of 2-inch pipe 2000 ft. long.

M. B. HART

Better handling of gas will add much to recovery of oil. J. F. SHAW. *Nat. Petr. News* 17, No. 34, 56-9 (1925).—Tables show the vol. of free gas (sea-level basis) contained in one gallon of petroleum under given pressure, the percentage of petroleum in an underground reservoir which will be lifted to the surface by the energy of the absorbed gas; vol. of free air (sea level basis) at a given pressure which is theoretically required to raise 1 gallon of water to a given height in feet; and the gas pressure at various fields.

M. B. HART

Losses in treating crude oil for bottom settlings. H. KAYE. *Oil & Gas J.* 24, No. 9, 101 (1925).—Serious loss in the gravity of crude oil occurs between the time the oil is pumped and when it is sent on to the pipe line. Remedies suggested in connection with an improved type of treating plant are. (1) Test wells for bottom settlings to det. the quantity of tret-o-lite necessary and the temp. required to break the emulsion, which may show the efficiency of settling. (2) Oil storage tanks should be tight with a thief opening which allows 10 to 50 sq. in. of oil surface in contact with air. (3) Plants should be arranged to allow 5 to 10 lbs. pressure if desired which will allow application of heat and permit more vapors to be adsorbed. (4) Keep temp. of oil const. (5) Draw water off the flow tank as far as possible; if possible pump through the 2-inch lead line directly into an upright joint of casing and siphon the water out. (6) A ventilated shed or umbrella to divert sun rays should be used.

M. B. HART

The formolite reaction. A. M. NASTIUKOV. *J. Ind. Chem. (Russia)* I, 28-30, May-June (1925).—The following modification of the original procedure is designed to facilitate the operation of freeing the formolite ppt. of the hydrocarbons which have not reacted. Condense in the usual way the oil, H_2SO_4 and formalin in the proportion 1 4 2. Reflux 1 hr. on the water bath and add 5 times its vol. of water. If some transparent oil (free of formolite) is supernatant, carefully remove by means of a pipet. Place the mass in a flask with an inverted air condenser and heat 1 hr. in a current of steam, neutralize with ammonia in excess and filter with suction. Wash the ppt. with water and benzine (or petroleum ether), dry at 100° and weigh. To the wt. in g. of the formalite add 5.25% (to account for the persistence of moisture and for the change of wt. due to the reaction with formalin); the number obtained is the formolite number. The formolite numbers obtained are about the same as those which are obtainable by the original method. By the modified process the formolite obtained is powder-like and never sticky and is, therefore, easily filtered and dried; it shows, however, after being dried at 100°, a considerable partial soly. in benzine (or petroleum ether).

BERNARD NELSON

Vacuum assay distillation test. A. G. PETERKIN, JR. AND S. W. FERRIS. *Ind. Eng. Chem.* 17, 1248-9 (1925).—A simple app. that can be operated easily has been developed. One hundred cc. of oil is used, and the temps. are read when 1, 3, 5, 10, 20, —, 90 and 95 cc. have distd. at the rate of 5 cc. per min. A pressure of 10 mm. has been found suitable. Comparison with the Bureau of Mines method (40 min.) can be made by adding 39° to each of the temps. Volatile products are distd. at first at at. pressure until the temp. in the vapor is 285°. A special pressure regulator is described. A capillary tube (1 mm. bore), slightly longer than the barometric height, is immersed to the proper depth in a tube of Hg. Since the capillary tube is open to the air and the space above the Hg in the tube communicates with the distn. app. and the pump but not with the air, bubbles of air escape from the capillary into the space above the Hg in the tube when the pressure is decreased by a h. of mm. of Hg equal to the depth of immersion of the capillary. To the bottom of the capillary is sealed a piece of tubing 7 mm. in diam. and 25 mm. in length. This tube is provided with a lip to insure regular escape of bubbles of air. Two or three strings extend from the lip to the air space above the Hg in the tube. Since these strings are not wet by Hg they provide channels through which the bubbles rise without disturbing the surface of the Hg. The results of the distn. of three motor oils are presented.

W. F. FARAGHER

Relation between boiling point and some other properties of petroleum products. J. B. HILL AND S. W. FERRIS. *Ind. Eng. Chem.* 17, 1250-2 (1925).—Crude petroleum were distd. at reduced pressure in the lab. with no special attempt to fractionate them. Steam was admitted when the rate of distn. became slow at temps. at which cracking had to be avoided. These fractions were examd. (Saybolt Universal viscosities at 100° and 210° F., sp. gr., refractive index, and pour-point) and were distd. in the vacuum

assay app. of Peterkin and Ferris (cf. preceding abstract). The relationships between the b. p. of the fractions when 50% had distd. and the various phys. properties of the original fractions are analyzed for each crude. The range of b. p. of the fractions varied from 75 to 115°. These fractions, therefore, are "close" and may be considered to approx. closely in phys. properties "closer" fractions having the same b. p. at the 50% point. Similar data should be useful in detg. the yields of lubricating oils and in detg. the compn. of an unknown blended oil.

W. F. FARAGHER

Tetraethyl lead poison hazards. T. MIDGLEY, JR. *Ind. Eng. Chem.* 17, 827-8 (1925).—Hazards in manuf., handling and mixing with gasoline, distribution of treated gasoline and using of treated gasoline are discussed. The advantages to the public attendant upon the use of PbEt_4 in gasoline are such that "unless a grave and unescapable hazard exists in the manuf. of PbEt_4 , its abandonment cannot be justified." Serious hazards are limited to manuf. and handling of PbEt_4 itself; these hazards are recognized and can be obviated. PbEt_4 is a slow poison, 0.05 as poisonous as HgCl_2 . The symptoms of poisoning are, in order of appearance, drop of blood pressure, drop of body temp., reduced pulse-rate, sleeplessness, loss of wt., nausea or tremor and delirium tremens. In early stages, removal from exposure gives complete restoration. If sleeplessness has developed, the patient is kept in the open air and given light exercise without use of soporifics.

W. F. FARAGHER

The cracking of ozocerite. E. R. TOPORESCU. *Compt. rend.* 181, 669-71 (1925).—Treatment under pressure of ozocerite with AlCl_3 gave:

% AlCl_3 used	Distn. begins	% Distillate	% Benzene	% Kerosene	Residue %
5	163°	33	6	19	8
15	123°	51	30	5	16
25	111°	12	7	2	3

An Engler distn. test of the distillate obtained with 15% AlCl_3 gave: b. p. 34°, to 70° 33% (of the rectified distillate), to 100° 65%, to 145° 90%, to 150° 100%, residue 1, loss 8% (of the original distillate). A certain amt. of unsatd. hydrocarbons is formed.

A. PAPINEAU-COUTURE

Bituminous shales as a source of hydrogen. CAMILLE MATIGNON. *Chimie et industrie Special No.*, 181-2 (Sept. 1925).—The gas obtained by the Société Lyonnaise des Schistes Bitumineux in Scotch retorts contains about 25% H_2 , which could be raised to 50% by preventing leakage of air. Its compn. after removal of CO_2 would be approx. CO 12, C_nH_{2n} 2, CH_4 18, H_2 68%. M. suggests recovering both H_2 and C_2H_4 by liquefaction by the Claude process and converting into NH_3 and EtOH , resp.

A. PAPINEAU-COUTURE

The bituminous deposits of Lattakia. P. M. F. SCHMITZ. *Matières grasses* 17, 7323-5, 7347-50 (1925).—Essentially a résumé of Marckwald's report (*C. A.* 16, 3201), supplemented by S.'s personal observations.

A. PAPINEAU-COUTURE

The neutralizing action of activated bleaching-clays on acidified lubricating oils. O. ECKART. *Z. angew. Chem.* 38, 885-7 (1925).—German clays (particularly from lower Bavaria) that have been "opened" with mineral acids have become strong competitors of bone-black and fuller's earth in the refining of oils. These clays have greater bleaching action than fuller's earth. The best of them contain when marketed about 0.036% of mineral acid, calcd. as HCl . They do not, however, increase the amount of acid in an acid-alkali-treated oil when as much as 3% by wt. of clay is used at 95° for 10-180 min. The acid of an acid-treated oil is removed more slowly by these clays than by fuller's earth, but almost the same removal of acid is effected (10 min for fuller's earth; 45 min. for clays). Oils that are decolorized by the clays in times shorter than 45 min. darken again during 2-3 days; the oils treated with clay for 45 min. or longer are permanently decolorized. The removal of acid by the clays is effected by adsorption, whereas fuller's earth effects the removal partly by chemical action. Oils are deacidified more thoroughly by dry clay than by moist clay. The ability of a clay to remove acid from an oil is related closely to its bleaching effect. The addition of 5% of CaCO_3 to a clay gave a product that removed acid from an oil as rapidly and thoroughly as fuller's earth. The addition of 2.5% of Na_2CO_3 or CaO gave a product that was superior to fuller's earth. The commercial fuller's earths that were used were shown to contain 1.7-6.5% of $\text{CaCO}_3 + \text{MgCO}_3$.

W. F. FARAGHER

Lubrication and lubricants. X. JACODER. *Industrie chimique* 11, 396-401 (1924); 12, 351-4, 492-6 (1925).—A review covering the utility of lubrication, qualities required of a good lubricant, manuf. of com. lubricating oils and greases and control of lubricants and of lubrication.

A. PAPINEAU-COUTURE

Composition and commercial applications of a few spirits of turpentine. GEORGES DUPONT AND (MISS) M. BARRAUD. *Chimie et industrie Special No.*, 474-81 (Sept., 1925); cf. *C. A.* 16, 4339-41.—Spirits of turpentine from Austrian black pine (*Pinus laricina austriaca*) was found to have the following compn.: *l*-pinene (and traces of nopinene) 96, a *d*-hydrocarbon (*d*-limonene?) 1, sesquiterpene 1, esters, oxidation products and *d*-tail products 2%. $[\alpha]_D^{20}$ of the products obtained from different trees varied from -25.35° to -48° , which is attributed exclusively to variations in the inactive pinene content. This is the first time such variations have been observed in the product from different individuals of the same species. Spirits of turpentine from Spanish black pine (*Pinus laricio*, "pino salgareno") was found to have the following compn.: *l*-pinene 90, *l*-limonene 5, sesquiterpene 1.5, oxidation products and tails 3.5%. These 2 spirits of turpentine have practically identical compns. and in com. syntheses would behave like Bordeaux spirits of turpentine. They are the only ones known to consist almost exclusively of *l*-pinene. Reactions in which inactive pinene gives max. yields could probably be carried out commercially on a mixt. of spirits of turpentine from black pine and from Aleppo pine which has a high *d*-pinene content. Spirits of turpentine from *Pinus longifolia* was found to contain: *l*-pinene 21.8, nopinene 9.7, *d*-terpene and Δ^3 -carene 37.6, *l*-terpene 1.7, oxidation products and longifolene 20.3, residue and tails 5.9%. Owing to a relatively high content of non-volatile constituents it has poor drying properties and must be redistd., only about 75% being used. Its use in the chem. industry will depend on ultimate utilization of the chem. properties of carene, which is the most important constituent. Spirits of turpentine from *Pinus pinea* was found to contain: *l*-pinene 16.7, *l*-limonene 75.4, sesquiterpene 6.6, residue 1.7%. It could be used as a source of *l*-limonene by sepn. of the *l*-pinene by means of an efficient distn. column.

A. PAPINEAU-COUTURE

Necessity of a precise definition of spirits of turpentine. DANIEL BÉGUERIE. *Chimie et industrie Special No.*, 465-7 (Sept., 1925).

Bordeaux pine (*Pinus maritimus*) and its industries. G. DUPONT. *Chimie et industrie Special No.*, 65-74 (Sept., 1925).—An address.

A. PAPINEAU-COUTURE

The future of the wood distillation industry. G. DUPONT. *Tech. moderne* 17, 725 30 (1925).—A discussion of the improvements required in the industry to allow it to compete with the synthetic production of AcOH and MeOH.

A. P. C.

Carbonization of Moroccan conifers. R. MASSY. *Chimie et industrie Special No.*, 183-5 (Sept., 1925).—Lab. distns. of "thuya" (*Callitris quadrivalvis*) gave charcoal 27.17-32.59, pure filtered tar 7.87-12.31, pyrolygneous acid 27.33-38.28, total acidity (as AcOH) 1.08-1.40, crude wood spirits (as 100% MeOH) 0.50-0.55%. The charcoal makes a very low-grade fuel. The tar (known locally as "er-reld") (d_{20}^{20} 1.078) gave on distn.: below 150° 1.81 (1.20 H₂O), 150-240° 20.28, 240-60° 13.99, 260-80° 7.57, 280-300° 5.65, residue 48.50%, had an acidity (as AcOH) of 1.59% and gave the Hirschsohn-Pepin test for oil of cade. Tar (known locally as "gatrane er-rekik") produced by native methods from cedar (*Cedrus atlantica*) is a black mobile liquid, $d.$ below 1, acidity (as AcOH) below 1%, 65% of which distils at 150-300° at atm. pressure and which gives the Hirschsohn-Pepin test for oil of cade. On neutralizing with CaO and evapg. to a sirupy consistency, the pyrolygneous acid from both woods gives a brown acetate rich in sol. tar, which could doubtless be used in therapeutics.

A. PAPINEAU-COUTURE

Measurement of the vapor tension of gasoline, etc. (DAVIS) 2. Thiosept oil (BELANI) 17. Filter and trap for purifying gasoline (U. S. pat. 1,563,259) 1. Filter for gasoline (U. S. pat. 1,563,247) 1. Apparatus for pressing paraffin (U. S. pat. 1,560,443) 1. Dehydrating emulsions by externally charged particles (U. S. pat. 1,562,712) 13. Rotary apparatus for dry distillation of ligneous acetate material (U. S. pat. 1,566,778) 1. Apparatus for distilling methanol from wood (U. S. pat. 1,562,880) 1. High-pressure hydrogenation of heavy mineral oils (Dutch pat. 13,594) 21.

American Petroleum Supply and Demand. By Comm. of Am. Petroleum Inst. New York: McGraw-Hill Book Co. 269 pp. \$3. Reviewed in *Mining Met.* 6, 590 (1925).

Treating natural petroleum emulsions. C. G. HINRICHS. U. S. 1,566,008, Dec. 15. A natural petroleum emulsion is mixed with a Cl deriv. of ricinoleic acid or other Cl addn. product of a liquid fatty acid in sufficient quantity to effect a sepn. of the

constituents of the emulsion. U. S. 1,566,009 specifies the use of KCNS or other H_2O -sol sulfo cyanide.

Electric dehydration of aqueous petroleum emulsions, etc. H. C. EDDY. U. S. 1,565,992, Dec. 15. After preliminary elec. treatment and sepn. of H_2O and solids the oil residue is filtered to effect further sepn. of H_2O .

Electric and centrifugal separation of oil and water in petroleum emulsions, etc. C. W. GIVIN. U. S. 1,565,997, Dec. 15.

Heat interchanger for petroleum oils and vapors. G. EGLOFF. U. S. 1,566,528, Dec. 22.

Distilling petroleum oils. F. M. CLARK. U. S. 1,566,828, Dec. 22. The heat from a fire-heated still and setting is utilized, at the end of a pressure-distillation of a heavy oil for the production of gasoline, for the treatment of the residues of the distn. which have a d. of about 20° Bé. After the still fire is withdrawn, steam is passed through the residues and the evolved vapors are condensed until about 60% of the oil of the residues has been removed and condensed. The residual material is then withdrawn from the still.

Cracking petroleum oil. B. T. BROOKS. U. S. 1,563,012, Nov. 24. A petroleum oil is cracked under conditions which produce a product rich in olefins. This material is treated with strong aq. H_2SO_4 of somewhat less than 66° Bé strength, the oil is sepd from immiscible substances, treated with alkali and distd. It is suitable for use as a "motor spirit" (This pat. was applied for May 1, 1918.)

Cracking hydrocarbon oils. F. G. NIECE. U. S. 1,565,326, Dec. 15. Vapors and gases from a cracking chamber are subjected to a condensing temp. Other hydrocarbon material such as fuel oil is fed to a body of molten Pb or similar molten material through an inner chamber in the molten body and at the same time gases and vapors remaining uncondensed from the condensing operation first mentioned are also heated by the molten material. U. S. 1,565,327 specifies an app. for carrying out this process.

Cracking oil and freeing it from carbon. L. D. WYANT. U. S. 1,563,818, Dec. 1. Oil is heated to cracking temp. and agitated to maintain C in suspension. Portions of the oil carrying C are ejected from the main body of oil in the heating chamber by the action of pressure directly generated through the gases and vapors evolved from the oil in the process and devices are provided for sepg. and discharging C from the oil in the still.

Apparatus for cracking hydrocarbon oils. F. G. NIECE. U. S. 1,566,341, Dec. 22. The app. is adapted for cracking oils by passing them through molten Pb or similar molten material.

Apparatus for cracking hydrocarbon oils by passing them through molten lead or similar material. F. G. NIECE. U. S. 1,566,416, Dec. 22.

Dephlegmator adapted for use in distilling hydrocarbon oils. J. W. HANCOCK. U. S. 1,564,464, Dec. 8.

Oil still. J. PRIMROSE. U. S. 1,566,921, Dec. 22. The still comprises banks or groups of tubes exposed to hot gases in different parts of their course and connections for taking off, returning to and causing to reflow through the hottest tubes only oil that has already passed through the still.

Apparatus for distilling petroleum and separating carbon from the products. W. H. STILSON. U. S. 1,564,984, Dec. 8.

Still for distilling and coking crude petroleum. P. YOUNG. U. S. 1,564,312, Dec. 8.

Petroleum still. M. F. DEBAJLIGETHY. U. S. 1,562,690, Nov. 24.

Oil and gas separating apparatus. C. J. WOLFE. U. S. 1,565,135, Dec. 8. The app. is adapted for sepg. gas and oil at wells.

Oil from shale. C. S. FOGH. U. S. 1,563,271, Nov. 24. Oil shales and oil sands are heated while being passed through a practically gas-tight rabble furnace, by contact with substantially non-oxidizing gases to vaporize volatile constituents and products in continuous flow. After sepn of a condensate from volatilized substances, the fixed gases are reheated and passed through the furnace as the heating agent.

Oil-shale retort. S. H. CORFIELD. U. S. 1,562,541, Nov. 24.

Retort for distillation of oil shale. J. T. POPE. U. S. 1,564,271, Dec. 8.

Preventing evaporation losses of gasoline or other substances from storage tanks. R. E. WILSON. U. S. 1,566,944, Dec. 22. A body of silica gel is connected with a vapor escape pipe from the tank and the silica gel is attemperated to a temp. at least as high during suction into the tank as that prevailing during expiration from the tank.

Revivifying fuller's earth. F. W. HALL. U. S. 1,562,550, Nov. 24. Spent material used in refining mineral oils is subjected to the distg. action of a carrier gas, e. g., steam, and is then heated in the presence of air to a higher temp. (cf. C. A. 20, 268).

Vanadium. H. L. BALDESCHWIELER. U. S. 1,563,061, Nov. 24. V is recovered from *petroleum ash* by treating it with an alk. reagent such as a hot 20% NaOH soln.

Lubricating oil. R. W. HANNA, O. E. CUSHMAN and T. W. DOELL. U. S. 1,566,000, Dec. 15. A lubricating oil of green fluorescence is obtained from a petroleum oil (such as one with an asphaltic base) normally yielding an oil of different fluorescence, by combining with the oil an oil from the residuum of a cracking process.

Refining lubricating oils. J. W. WEIR. U. S. 1,564,501, Dec. 8. Lubricating oil stock is treated with H_2SO_4 , allowed to settle and the major portion of the sludge is removed. A comminuted solid adsorbent material such as bauxite or fuller's earth is then added and the mixt. is heated sufficiently to decompose the remaining sludge and liberate SO_2 . The adsorbent material is then sepd.

Viscous oily liquids from acetylene and coal-tar hydrocarbons. L. LILIENFELD. U. S. 1,563,203, Nov. 24. C_2H_2 is brought into contact with coal-tar hydrocarbons b. above 140° in the presence of $AlCl_3$. Products are obtained which are clear to yellow oils of high viscosity and possess *lubricating properties*.

Packing asphalt. H. R. DILLEHAY and A. R. LUKENS. U. S. 1,565,798, Dec. 15. Asphalt is prevented from adhering to the inner surface of paper cartons by lining them with a mixt. of Fe oxide, lampblack and clay or similar materials.

Distilling and refining asphalt or similar materials. D. PYZEL. U. S. 1,562,723, Nov. 24. Liquid bituminous substances such as asphalt or asphaltic residuum are mixed with sand, sawdust, coke, coal or other solid matter and the mixt. is passed through a rotating kiln in the form of coherent balls in contact with hot non-oxidizing gases which serve to effect distn. and coking.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

The determination of α -cellulose. C. G. SCHWALBE. Tech.-Wiss Teil, *Papierfabr.* **23**, 697-705(1925); cf. C. A. **20**, 283.—A detailed report of the German Fiber Analysis Comm. on the detn. of α -cellulose in sulfite pulp. Comparative tests on 4 sulfite pulps from different countries in 7 German labs. using the Jentgen, the Waentig and the Comm. methods demonstrated that accurate check analyses were not possible: the Waentig procedure gave the most deviating values; the Jentgen method gave the highest and most const. figures; and the other method came between these two. The Comm. method: Treat 3.5 g. air-dry pulp, cut into pieces 1 cm. sq., with 75 cc. 17.5% NaOH soln. (less than 2% Na_2CO_3) in a 250cc. beaker for 1 hr. at exactly 20° by using a thermostat or a water bath. Then crush the mass in a porcelain mortar until homogeneous, cover with a crystg. dish and allow to remain for 30 min. at room temp. (20°). Filter on a Buchner funnel, without filter, refilter, soak for 2 min. in 8% NaOH soln. at room temp., suck off and so treat until 200 cc. are consumed. Wash with distd. water till free from alkali, add 50cc. AcOH soln. (5%), suck off after 2 min. and wash until neutral. Dry in a glass weighing bottle at 105° to const. wt., and det. the ash content. The influence of time, temp. and the method of mixing are discussed. Substitution of the mixing operation by a beating or a rasping of the pulp is not advised. The use of Turkey-red oil as an aid to uniform mercerization is suggested. Three suggested α -cellulose methods were also compared with the others. It is recommended that a compromise be made between the Jentgen procedure and one of the modified methods, which latter consists in treating 3.5 g. air-dry pulp with 50 cc. 17.5% NaOH soln. for 45 min. with frequent stirring. Filter on a porcelain funnel without filter, wash with 400 cc. 8% NaOH soln., with distd. water to neutrality (2 l.), with 100 cc. AcOH and finally with water. Before drying to const. wt. at 105° , wash the mass with abs. EtOH.

J. L. PARSONS

Cable paper. E. BELANI. Tech.-Wiss Teil, *Papierfabr.* **23**, 728-9(1925).—The properties and manuf. of paper for cable insulation are briefly described. Its use as a carrier of thin sheets of metals, as permalloy (78% Ni, 22% Fe), etc., is mentioned. The application of the Schoop metallizing process is discussed. J. L. PARSONS

Reeds for the manufacture of pulp in Russia. V. IUFIRIEV, M. MILJEANT and A. KOGAN. *Zellstoff u. Papier* **5**, 445-6(1925).—*Phragmites communis* from the Dniest River region in Russia yields a stalk of relative high density and an ash content of approx. 6% (of which 84.4% is SiO_2 , 2.7% Al_2O_3 and Fe_2O_3 , 1.5% $Ca(OH)_2$, 0.8% $Mg(OH)_2$ and 10.6% alkalis, H_3PO_4 and Mn). Ultimate analysis gave 5.3% H, 42.8% C and 37.8% N and O. The pulp content (method of Henneburg and Stomann)

of the stem was 51.8% (ash 9.29%) and of the leaf portion 25.2% (ash 0.79%). By the soda process, a yield of 33.3–36.1% pulp from the stems and 21.3–24.2% from the leaf portion was obtained. The digested fibers were 2–3 mm. long and thin and cylindrical in shape, resembling silk. They possess qualities suitable for the manuf. of bag paper.

J. L. PARSONS

Review of the patent literature on chemical processes for the purification and refining of pulps and fibrous materials, 1898–1925. A. SCHROBE. Tech.-Wiss. Teil, *Papierfabr.* 23, 655–8, 687–9(1925).—Brief abstracts of 66 German and foreign patents.

J. L. PARSONS

Roots of the licorice tree as raw material for paper. ANON. *Zellstoff u. Papier* 5, 400(1925).—The licorice tree (*Glycyziza glandulifera uralensis*) grows abundantly in Turkestan, its roots contg. about 20% licorice, of which 18–19% is extd. The extd. residue cooked 4 hrs. in an autoclave with 15% $\text{Ca}(\text{OH})_2$ or 5% NaOH at 3 atm. resulted in pulp fibers similar to esparto, 3–4 mm. long and 0.015 mm. thick. The yield of paper stock, based on the dry wood, was about 50%. Paper made in this manner appeared suitable for packing purposes. Phys. tests on hand-made sheets yielded a tearing length 1050–2040 m., a % stretch 2.7–6.5 and a folding endurance 5–16.

J. L. PARSONS

Paper and pulp from beech wood. ANON. *Zellstoff u. Papier* 5, 401(1925).—Beech wood yields a superior sheet and a pulp which is softer than spruce pulp. It finds use in the manuf. of artificial silk, explosives and celluloid. As a by-product of the digestion process, a N substance is available for fertilizer purposes.

J. L. P.

Effect of heat on the strength properties of bag paper. W. HERZBERG. *Wochbl. Papierfabr.* 56, 1393–5(1925); Tech.-Wiss. Teil, *Papierfabr.* 23, 748–50(1925).—The results of a large no. of tests on the effect of heat on bag papers used for holding cement, etc., are summarized as follows: (1) compared with the paper sheets under ordinary conditions, paper made from soda pulp yielded a 22% and an all sulfite paper a 11% higher tearing length after a 24 hr. exposure to 80° and immediate testing; (2) similarly the % stretch was reduced to 51 with the soda paper and to 63 with the sulfite sheet; (3) the folding endurance was decreased to 15% with the soda and to 2% with the sulfite and (4) the bursting strength was 7% less with both papers. It was shown that cement bags made from soda pulp are preferable.

J. L. PARSONS

Differentiation between sulfite and soda pulp fibers in paper. KORN. *Wochbl. Papierfabr.* 56, 1417–20(1925).—In using the Lofton and Merrit stain for the differentiation and estn. of unbleached sulfite and soda pulp fibers in paper, the red coloration of the former is more intensive than the blue color of the latter, thereby leading to an over-estn. of the sulfite pulp constituent. A modified form of Wisbar's staining method permits of a more accurate microscopic examn. Further testing of the Alexander staining method showed that all sulfite pulp fibers, as well as soda pulp fibers from deciduous trees, straw, esparto and grass in the bleached condition, give the characteristic coloration. Soda pulp fibers from many coniferous woods, especially pine, cannot be distinguished with certainty from sulfite fibers. The method may be simplified by omitting the Congo red staining treatment and the use of a more concd. $\text{Ca}(\text{NO}_3)_2$ soln.

J. L. PARSONS

Lignin (KÜSTER, SCHNITZLER) 10. Homogeneity of α -lignin (HAGGLUND) 10. Constitution of pine wood lignin (KLASON) 10. Relation of moisture content of wood to its decay (SNELL, *et al.*) 20. Drying and oxidizing paper (U. S. pat. 1,564,565) 13.

Cellulose ether compositions. L. LILIENFELD. U. S. 1,563,204, Nov. 24. Moldable compns. are formed from ethyl cellulose, benzyl cellulose or other alkyl, aryl or aralkyl ethers of cellulose, plasticized by the addn. of oily products obtained by the action of C_2H_2 on tar oil constituents b. above 140° in the presence of AlCl_3 . Cf. C. A. 19, 3592.

Esterifying cellulose. N. B. GRILLET. U. S. 1,566,398, Dec. 22. In esterifying cellulose, *e. g.*, to produce cellulose acetate, the reaction is carried out in the presence of a liquid solvent of the desired reaction product in a comparatively large closed vessel which is rotated to agitate the mixt.

Recovering acetic values from cellulose acetate mixtures. E. S. FARROW, JR. U. S. 1,536,334, May 5, 1925. Cellulose acetate particles contg. less than 50% HOAc are agitated with an excess of EtOH at 75° until the HOAc is removed from the particles and converted to EtOAc . Air is blown into contact with the particles to take up and carry away vapors of the residual alc. and EtOAc and the latter are condensed and sepd. Other alcs. may be used instead of EtOH . An app. is described.

Fuel, etc. from sulfite cellulose lye. C. G. SCHWALBE. U. S. 1,564,142, Dec. 1. Sulfite cellulose lye is mixed with sawdust and chlorides of Mg, Ca or Na and the mixt. is heated to 150–200° under pressure to produce a material adapted for use as a fuel after leaching out sol. salts, etc.

Cooking pulp. W. D. GREGOR, W. M. OSBORNE and A. J. KEMZURA. U. S. 1,565,090, Dec. 8. A digester is partially filled with cooking liquor such as acid sulfite soln. and the material to be pulped, *e. g.*, wood in chip form, is fed into the partially filled digester in such amt. as will permit its circulation during the cooking, additional cooking liquor being then introduced to complete the charge.

Fiber board. A. L. CLAPP. U. S. 1,566,309, Dec. 22. A dry moldable material is produced by heating out cellulose in the presence of animal matters such as waste hair or hide scraps and H₂O until the cellulose is hydrated to the point of sluminess. The material is then formed into sheets. U. S. 1,566,310 specifies making dense hard fiber board by heating cellulosic material such as waste kraft paper until the fibers are well hydrated, sheeting, drying and subjecting to high pressure.

Rotating digester for wood pulp. E. MORTERUD. U. S. 1,566,339, Dec. 22.

Film-forming composition. H. A. GARDNER. U. S. 1,564,664, Dec. 8. Nitrocellulose or other "organo oxy-cellulose compd." is used with a toluene sulfoamide-aldehyde resin.

Reducing viscosity of nitrocellulose. N. S. KOCHER and V. E. KIMMEL. U. S. 1,564,689, Dec. 8. Nitrocellulose is treated with a soln. contg. HCl or other inorg. acid together with an alkali metal chlorate, *e. g.* KClO₃, to reduce its viscosity characteristics. The reaction is stopped before the demitration reduces the N content below 9.5%. The resulting product is adapted for forming solns. for spraying.

Removing pyridine from nitrocellulose. L. W. EBERLIN. U. S. 1,564,765, Dec. 8. Colloidized nitrocellulose contg. pyridine is treated with a chlorinating agent such as Cl₂ gas in the presence of a mixt. of H₂O and a penetrant, *e. g.*, acetone 20 and H₂O 80%, until the pyridine is substantially decomposed. The nitrocellulose is then removed from the mixt. and treated with Na₂S₂O₃ or other "anti-chlor" soln. to neutralize free Cl.

Celluloid printing plates. H. RENCK. U. S. 1,565,815, Dec. 15. The surface of a celluloid plate is softened by glacial HOAc or other suitable solvent, the softened surface is coated with an aq. soln. of gelatin contg. glycerol and HOAc or other softening agent for celluloid, the gelatin coating is dichromated, exposed and developed.

Branding carbon paper. H. W. A. DIXON. U. S. 1,565,310, Dec. 15. Different parts of the backing sheet are heated to different temps. to cause absorption of different proportions of the transfer material and produce a marking after cooling.

Preventing f. oth on paper machines. W. E. METCALF. U. S. 1,532,597, April 7, 1925. Mech. features.

Rubber rolls for paper-making machines. R. B. ADAMS and F. R. WOODWARD. U. S. 1,563,943, Dec. 1. The surfaces of top press rolls are formed of rubber and sugar, NaCl or other H₂O-sol. substance.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

Safety in the manufacture of nitric, sulfuric and mixed acids and nitrate of ammonia as used in the manufacture of explosives. S. H. KERSHAW. *Ind. Eng. Chem.* **18**, 4–9(1926).—The safety methods developed by the Hercules Powder Co. are described in considerable detail. F. C. Z.

A comparison of the theory of explosive waves with recent tests. E. JOUGUET. *Compt. rend.* **181**, 546–8(1925).—Previous calcs. of velocities of explosive waves, to compare with observed values, have used the sp. heats of Mallard and Le Chatelier. A table gives a comparison with those obtained from the Kast formula from tests by Pier and Bjerrum, the degree of dissociation being detd. by extrapolating present knowledge of dissociation of H₂O and CO₂ and assuming no residual combustion. Presence of a reversible residual combustion lowers the calcd. velocity a little. The agreement between the calcd. and the exptl. results is satisfactory for H₂ but less so for CO but the divergence is insufficient to condemn a theory evidently approx. and whose causes can be explained. The high values of abs. temp. show that the calcn. requires great extrapolation of the dissociation law and sp. heats and is, therefore, very uncertain. It is now known that the Mallard and Le Chatelier formulas rise too rapidly while perhaps that of Kast may rise too slowly. E. M. SYMMES

Shock waves and residual irreversible combustion (of explosives). E. JOUGUET. *Compt. rend.* **181**, 658-60(1925); cf. preceding abstract; Audibert, *C. A.* **18**, 3478.—When partial combustion takes place within an explosion wave, it is because the rate of reaction is enormously high; while in residual combustion the rate of reaction, though still very high, is not enormous. The transition from very high to enormous rate of reaction is doubtless continuous, but probably rapid. From a mathematical discussion J. shows that if the expansion of the gases is decreased a point is reached at which residual combustion becomes instantaneous and the explosion wave proper is formed. This is the case of the preliminary waves which, in Lafitte's expts., precede the explosion wave in a mixt. of gases fired by an elec. spark. The transformation of these waves into an explosion wave is facilitated by anything that retards expansion back of the wave front, e. g., friction against the walls, which explains why they are formed more rapidly in narrow than in large tubes. It is conceivable that a wave might have a uniform velocity, unaffected by conditions back of the wave front; but such a wave would be extremely rare, as it would follow that there must be compression of the fluid back of the wave front.

A. PAPINEAU-COUTURE

Production of colored smoke signals. A. B. RAY. *Ind. Eng. Chem.* **18**, 10-7 (1926).—Colored smokes were prepd. by volatilizing colored org. materials and the black smoke by thermal decompn. of an org. material of high C content, like anthracene. Volatilization is by a smothered combustion, with chlorates as oxidizers and cheap dyes. Special containers are required to regulate rate of burning. Fair smokes are obtained by exploding containers of rouge or ultramarine but large amts. are necessary. Gaseous reactions were unsatisfactory. Smokes from As_2S_3 or I_2 fade rapidly. Satisfactory parachute and non-parachute rocket, rifle grenade, Very pistol, hand grenade for aviators and smoke pot signals were developed.

E. M. SYMMES

Explosive. N. A. UNGER. U. S. 1,566,784, Dec. 22. An explosive which is suitable for blasting comprises NH_4NO_3 50-85, Si 10-40 and nitroglycerin (gelatinized with nitrocellulose) 1-15 parts

Propellent explosive. C. R. FRANKLIN. U. S. 1,564,549, Dec. 8. Nitrocellulose contg. about 12.6% N is mixed with a large excess of H_2O and nitroglycerin is then agitated with the mixt., the excess of H_2O is wrung out and a stabilizer such as diphenylamine and a flash-reducing compd., e. g., hydrocellulose, are added. The material is passed through heated pressure rolls, seasoned, mixed with acetone or other volatile solvent, again passed through heated rolls, cut and dried. Cf. *C. A.* **19**, 3021.

Explosive charges containing liquid oxygen or air. G. WEBER. U. S. 1,565,766, Dec. 15. Mech. features of forming cartridges in mine holes.

Detonator for liquid-oxygen explosives. C. MORR. U. S. 1,563,219, Nov. 24. Mech. features.

Blasting powder. C. D. PRATT. U. S. 1,563,924, Dec. 1. The constituents of black powder are mixed with a carbohydrate material such as starch 5-35 and a metallic chloride, e. g., NaCl 1-15%. U. S. 1,563,925 specifies a similar powder except that Na K tartrate and NH_4 oxalate or other tartrates and oxalates are used instead of chloride. U. S. 1,563,926 specifies the addn. of non-explosive substances deficient in O such as starch, paraffin and rosin, in similar explosive powders.

Fastness of dyes on cotton and wool. G. A. SACKETT. *Textile World* **68**, 2629-31, 3221-3, 3281(1925).—An English translation of the German "Second Public Report of the Fastness Committee," *C. A.* **11**, 2963.

CHAS. E. MULLIN

Relation of Monel metal to dyeing and textile machinery. J. F. HAERRY. *Chemicals* **24**, No. 19, 23(1925).—Monel metal is advantageous for most vat, direct, acid and Cr dyes. While it does not affect most S dyes, it is severely attacked by the sulfide. It is suitable for black and most other developed colors, but is not suited for use with naphthol AS and BS colors as the traces of metal in soln. decompose the diazonium compds. very rapidly, giving poor, dull dyeings. When used for stripping with Na hyposulfite, the soln. should be kept alk.

CHAS. E. MULLIN

Method for producing white and multicolor effects on fabric dyed with sulfur colors. ARTHUR SCHEUNERT AND JOSEPH FROSSARD. *Bull. soc. ind. Mulhouse* **91**, 551-7

(1925).—Sealed notes 1775 of Oct. 18, 1907, 1794 of Dec. 16, 1907, 1799 of June 2, 1908, 1813 of March 10, 1908. *No. 1775*.—Better results were obtained by printing a resist of Mn chloride and ZnO instead of ZnSO_4 and ZnO. It is applied on the white, thoroughly dried, mercerized fabric, which is then dyed with a S dye, dissolved either in alk. hyposulfite or in Na_2S and Na_2CO_3 . Light colors are dyed cold and deep colors at 60–70°. For black and white, print the white reserve and aniline black, put through a Mather-Platt, and dye as above. To obtain red, garnet, or azo black, jig the mercerized fabric in Na naphtholate and print the diazo dyes with resist for white; to make the resist colors as concd. as possible use the double salts of the diazo dyes with ZnCl_2 or with $\text{Al}_2(\text{SO}_4)_3$, or the nitrosoamines. The reserve alone on Na naphtholate gives a perfect white. The development of the azo shade, which forms rather slowly in the acid medium, is accelerated by drying thoroughly and passing for 45–60 sec. in a Mather-Platt. *No. 1794*.—In order to get yellow, blue, violet and green, which cannot be obtained with diazo dyes, dyes were selected which are not pptd. by ZnCl_2 or Mn chloride and which can be fixed by passing 1–2 min. in a Mather-Platt. As basic dyes are nearly all pptd. by ZnCl_2 , AcOH and PhOH or resorcin was added to prevent pptn. For yellow, Nietzsky yellow with ZnCl_2 and Cr bisulfite was used; for violet, Sandoz' pure plum dissolved in PhOH with ZnCl_2 and Cr bisulfite; for blue, setocyanine dissolved in glacial AcOH and PhOH with ZnCl_2 and tannin; for green, a mixt. of Mietzky yellow and of setocyanine. All these dyes are fixed better if the fabric is treated with Na naphtholate, the alk. of the latter neutralizing the acidity of the ZnCl_2 . The white and colored resists also give good results with many dyes which are converted into sol. leuco derivs. by alk. hyposulfite, e. g., indanthrene, flavanthrene, dianthrene blue, algol blue, algol rose, thioindigo red, thioindigo scarlet. *No. 1799*.—Of the last-mentioned colors, dianthrene blue gives the best results. *No. 1813*.—Good resist colors were obtained by fixing basic colors on Zn tungstate as follows: add 100–150 g. Na tungstate to the Na naphtholate, apply to the fabric by jigging, print with a soln. of the basic colors in a mixt. of lactic acid and AcOH contg. the resist and ZnCl_2 , dry, pass twice in a Mather-Platt, dye in a Na_2S soln. of the dye, rinse, acidify and wash. **Report.** C. ZUNDEL and X. VOGT. *Ibid* 557–8—Ger. pat. 130,628 of May 30, 1901, to L. Casella & Co., covers the use of Zn, Cu, Mn, Pb or Ni salts for resists, but does not give any details as to the method of using them. Ger. pat. 215,128, of Nov. 23, 1907, to Fellmayer & Co., Schwechat, Austria, covers a process for reserving under an indigo vat, characterized by the use of manganous salts in the resist. L. Baumann and G. Thesmar published an article along similar lines (*C. A.* 2, 2623). No priority was found for the fixation of basic colors by means of Na tungstate; but Z. and V. did not obtain a very satisfactory fixation, owing to pptn. of the dyes by the ZnCl_2 .

A. PAPINEAU-COUTURE

Use of sodium silicate for printing vat dyes. EMILE ZUNDEL and LOUIS LANTZ. *Bull. soc. ind. Mulhouse* 91, 559–60(1925). Sealed Note 2088 of May 22, 1911.—A 35° Bé. soln. of Na silicate can be used instead of Na_2CO_3 or K_2CO_3 , a given alk. being thus obtained more cheaply than with the carbonates. **Report.** PIERRE BINDER. *Ibid* 560–1.—No anteriority was found. P. found the process gave good results on a small scale, but doubts if it would give satisfactory results with thin printing mixts because of the jelling of the water glass on dilm.

Water-retaining properties of wool fabrics. B. G. B. SLOCOMBE. *Canadian Colorist & Textile Processor* 5, 270-2(1925).—The results of various expts. with hydro-extractors in the removal of H_2O from wool fabrics are given in 4 tables. Lining the extractor cage so as to allow the free passage of air and water materially increases the drying efficiency. CHAS. E. MULLIN

Chemistry and physics of the wool fiber. F. A. HAYES. *Textile World* 68, 2083-5 (1925); cf. *C. A.* 19, 3023.—A general discussion of the constitution, reactions and phys. properties of wool. CHAS. E. MULLIN

Problems relative to the washing of woollens. H. L. TIBA 3, 1021-7, 1149-53 (1925).—After briefly reviewing the various theories suggested to account for the cleansing properties of detergents, L. reviews L. Rinaldi's expts. and results on the deterative action of glue and similar colloids, which showed that : (1) for scouring raw wool glue gave a 4-5% higher yield of wool, was easier on the fiber and gave a better feel than NaOH and can be used to advantage in admixt. with soap; (2) in dyeing, glue is better than Na_2SO_4 for obtaining proper penetration and evenness of dyeing and protects the fiber with resultant increase in yield and strength of the dyed fiber; (3) felting of the wool is facilitated and accelerated by addn. of glue instead of NaOH to the soap. Starch paste also improves the deterative properties of soap, but is more difficult than glue to remove subsequently. Addn. of glucose increases the deterative properties of soap considerably and also exerts a protective action similar to that of glue.

A. PAPINEAU-COUTURE
A "rustling" dressing for cotton. CHARLES SUNDER. *Bull. soc. ind. Mulhouse* 91, 561-2(1925).—Starch dressing contg. a triglyceride (but no Na soap) can impart to cotton "rustling" properties somewhat similar to those characteristic of silk which has been slightly acidified before drying. Such a dressing can be prepd. as follows: melt 180 parts of coconut oil with 10 parts of oleic acid, let cool, add with stirring 20 parts of 10° Bé. NaOH, and finally add water with gentle stirring to 400 parts. Use about 1 l. to 100 l. of starch dressing. A. PAPINEAU-COUTURE

"Philanization." (Production of wool effects on cotton.) CHARLES SCHWARTZ. *Tiba* 3, 1129, 1131(1925).—By action of strong HNO_3 (exact concn. not stated) at 0° on cotton fibers in presence of starch, incrustants, or proteins (e. g., by action on unbleached cotton) the fibers are given a decided woolly effect, which it is extremely difficult to obtain with bleached cotton. A. PAPINEAU-COUTURE

The chemical nature of artificial silks and of hydrocellulose. ROBERT HAZARD. *Tiba* 3, 1217-21(1925).—Brief review of recent work on the subject. A. P.-C.

The use of artificial (synthetic) fatty acid esters as textile fats for textiles. WELWART. *Seifensieder Ztg.* 52, 861(1925).—Referring to P. Spiess' recent article (*Spinnerei u. Weber* No. 41) on Me and Et esters as textile fats, W. reports that they had been successfully used in 1904 and that olein and the fatty acids from rape, olive, coconut

and palm kernel oil and from S oil can be used for producing such esters. In certain woolen goods the cheaper mineral oils are used instead; they can easily be washed out again with the aid of a little "hydraphtal." P. ESCHER

Comparison of the shades of cottons of different growths when dyed together in the same bath. D. A. CLIBBENS and B. P. RIDGE. *J. Textile Inst.* **16**, 305-10T (1925).—The differences of shade cannot be ascribed to chem. differences in the bleached cottons, but must be due to some characteristic variation from growth to growth in the structure of the individual hairs. For certain growths it was found that the order of shade in simultaneous dyeing is identical with the order of wall thickness of the hairs as measured by the hair wt. per cm. of length. The fine Sea Island and Egyptian Sakel cottons dye the lightest, and the coarser American and Indian cottons the darkest shades. Abnormally thin walled immature or "dead" cotton dyes a very light shade when compared with mature cotton in the same dye bath. L. W. RIGGS

Micro-technic of textiles. F. J. HOXIE. *Textile World* **68**, 3087-9 (1925).—A brief discussion of the uses and methods of using the microscope in a textile plant. CHAS. E. MULLIN

The inside story of Ford textile experiments. D. G. WOOLF. *Textile World* **68**, 2773-5 (1925).—A general description of the linen and woolen plants. C. E. M.

Variations in yarn structure. BROMPTON. *Textile World* **68**, 2807, 2819 (1925).—A consideration of the characteristics imparted to woolen and worsted yarns by the various systems of manuf. and their effect upon the fabric. CHAS. E. MULLIN

A dictionary of stain-removal. A. CHAPLET. *Tiba* **3**, 1011-51, 1155-63 (1925).—Numerous formulas are given for removing various kinds of stains. A. P.-C.

Preparation of sodium chlorate in dye-houses. H. SUNDER. *Chimie et industrie Special No.*, 374-8 (Sept., 1925).—When NaClO_3 is not readily available it can easily be prepd. by absorbing Cl in NaOH soln. (Na_2CO_3 should not be used), with cooling, to distinct acid reaction (but not to satn.), letting stand overnight, and adding a slight excess of aq. NH_3 . When properly conducted, a practically quant. yield of NaClO_3 is obtained. Efficient means should be provided for carrying off the toxic fumes given off when the hypochlorite soln. turns acid, and especially during addn. of NH_4OH . A. PAPINEAU-COUTURE

Dyeing and tanning in relation to one another (KÜHL) **29**. Fungi dyestuffs (KÖGL, POROWSKY) **10**. Water supply for textile mills (HUBBARD) **14**.

Dyes. G. DE MONTMOLLIN and G. BONHOTE. U. S. 1,534,506, Apr. 21, 1925. Non-hydroxylated nitrodiazo compds. (e. g., those prepd. from *m*-nitroaniline, 2,4-dinitroaniline or 2,6-dichloro-4-nitroaniline) are combined with ethylbenzylamine-sulfonic acid or other aromatic monamine of the benzene series not derived from metanilic acid and substituted at the N atom by a residue contg. a benzene nucleus (only one of the components contg. a sulfonic group). The dyes formed are orange to violet blue and greenish black powders which yield on acetylcellulose, when dyed in a dil. acid or neutral bath, yellow to bluish red and brown tints of good fastness to washing and to light.

Vat dyes. H. NERESHEIMER. U. S. 1,562,468, Nov. 24. In the manuf. of a chlorinated dibenzanthrone vat dye, dibenzanthrone is treated with Fe, Sb or other chloride which is capable of being converted into a chloride of lower valence during the reaction. Trichlorobenzene may be used as a diluent.

Vat dyes containing sulfur. E. HOFFE and H. HEYNA. U. S. 1,537,928, May 12, 1925. 9-Halo-3(2)- α -naphthothiophenone derivs. are condensed with reactive α -substitution products of isatins. The dyes produced give a blue color on cotton and are of good fastness.

Monoazo dyes. K. THIESS. U. S. 1,540,664, June 2, 1925. Dyes which dye wool greenish yellow to reddish yellow fast tints correspond to the formula $\text{CHO}-\text{R}-\text{N}:\text{N}-\text{R}'$, in which R is a benzene residue, which may be substituted in any way, contg. the aldehyde group in *m*-position, and R' stands for arylpyrazolones, their derivs. and substitution products. Several examples of specific dyes are given.

Monoazo dyes. K. THIESS. U. S. 1,540,665, June 2, 1925. Monoazo dyes giving yellowish red, bluish red, and violet red to brown fast tints on wool are obtained by coupling the diazo compds. of *m*-aminobenzaldehyde and its substitution products and compds. capable of splitting off *m*-benzaldehyde with the α -naphthol-mono- and poly-sulfonic acids in which 1 H of the amino group may be replaced by alkyl, aryl or acetyl. Several examples are given. U. S. 1,540,666 relates to similar dyes in which

naphthol-2,6,8- and 1,4,7-disulfonic acids and naphtholtrisulfonic acids are used as components.

Disazo dyes. W. BERGDOLT and L. HAUCK. U. S. 1,538,373, May 19, 1925. A diazo compd. of the benzene or naphthalene series is combined with 4-methyl-2-aminobenzoic acid, further diazotized and combined with a 2-amino-5-naphthol-7-sulfonic acid compd. The dyes formed dye cotton directly violet to blue shades fast to light which by after-treatment with CuSO_4 or similar metal salts change to bluish violet to violet-blue shades of great fastness.

Diphenyldicarboxylic acid disazo dyes. R. STÜSSER. U. S. 1,538,414, May 19, 1925. Azo dyes are made from 4,4'-diaminodiphenyl-3,3'-dicarboxylic acid and 1 mol. proportion each of 2 other components (*e. g.*, *N*-phenyl-2-naphthylamine and 1-*o*-hydroxyphenyl-3-methyl-5-pyrazolone) one of which contains a group augmenting the soly. These dyes dye cotton generally yellow to orange to violet to brown shades which by an after-treatment with Cu salts generally change to deeper shades fast to light and washing.

Trisazo dyes. A. I. LASKA and A. ZITSCHER. U. S. 1,540,485, June 2, 1925. Dyes giving black-violet to black tints of good fastness to washing are obtained by combining the tetrazo compd. of a diaminoazo compd. which does not contain a sulfo group, with an arylide of 2,3-hydroxynaphthoic acid. Numerous examples are given and among the components which may be used are *m*- and *p*-nitroaniline and their derivs., such as chloronitroanilines, nitrotoluidines, nitroanisidines, nitrothioanisidines, nitronaphthylamines, the corresponding monoacyldiamines, *m*-toluidine, *p*-xylydine, *p*-cresidine, acetyl-*m*-tolylenediamine, α -naphthylamine and such of its derivs. as are adapted to combine in the 4-position.

Brown trisazo dyes. B. VOSSEN. U. S. 1,565,344, Dec. 15. Dyes adapted for use on leather are obtained by prepg. monoazo dyes from diazotized amines or their substitution products with resorcinol or its substitution products, *e. g.*, chlororesorcinol, 1,3,4-resorcylic acid and similar compds., and then coupling with a diazotized aminonaphthol or its substitution products and finally causing diazotized amines or their substitution products to react upon these products. Sulfanilic acid, picramic acid and other starting materials are specified as suitable.

Tetraisazo dyes. J. P. PENNY. U. S. 1,549,214, Aug. 11, 1925. Two mol. proportions of a diazotized aminoazo compd. (or 1 mol. proportion each of 2 different compds. of this character) are coupled with 1 mol. proportion of 5,5'-dihydroxy-2,2'-dinaphthylurea 7,7'-disulfonic acid (the symmetrical urea of 2,5-aminonaphthol-7-sulfonic acid). Aminoazo compds. are used which are derivable from a β naphthyl-aminedisulfonic acid and, as second component, a primary amine of the benzene series having a free *p* position. The dyes produce, generally, bluish red shades on cotton.

Pyrone dyes. M. WEILER. U. S. 1,532,790, Apr. 7, 1925. 2,4-Dihydroxybenzoic acid compds. or their mixts. with aromatic aldehydes substituted in the *o*-position to the CO group or such aldehydes as contain neither substituents in the *o*-position nor an OH group in the *o*- or *p* position to the CO C atom are condensed and the resulting leuco compds. are oxidized or sulfonated. Dyes are obtained which dye wool from acid baths yellow-orange to red and after chroming from red-orange to brown-red fast to alkali, fulling and potting.

Dyes of the anthraquinone series. J. BADDILEY and W. W. TATUM. U. S. 1,540,733, June 2, 1925. Dyes giving brilliant blue shades on wool are obtained by condensing diaminoanthraquinones, *e. g.*, 1,4-diaminoanthraquinone, with a carboxylic acid of an alkylene oxide, *e. g.*, phenylglycidic acid. The dyes may be used for dyeing "acetyl silk."

Sulfonated "oxy-dianthraquinonylamine" dyes. W. MIEG and H. RAEDER. U. S. 1,564,091, Dec. 1. 1,1'-Dianthraquinonyloxazinesulfonic acids substantially free from dianthraquinonylaminesulfonic acids, which may be prepd. by heating 1,1'-dianthraquinonylamine to 120–125° with fuming sulfuric acid, dye wool from an acid bath brownish violet shades. The same shades are obtained by after-chroming or by dyeing chrome-mordanted wool.

Quinonimide dyes. A. G. GREEN, K. H. SAUNDERS and E. B. ADAMS. U. S. 1,551,147, Aug. 25, 1925. Dyes of the quinonimide class derived from the general

formula $\text{C}_6\text{H}_4 \begin{array}{c} \text{N} \\ \diagup \quad \diagdown \\ \text{C}_6\text{H}_4 \end{array}$ in which A stands for N, O or S are prepd. by applying a

standard reaction for the prepn. of oxazines, thiazines and azines, to intermediates contg. at least 1 hydroxyalkyl group attached to N in turn attached to 1 of the benzene rings. Numerous detailed examples are given.

Dyes containing chromium. F. STRAUB. U. S. 1,551,073, Aug. 25, 1925. Dyes contg. Cr (such as those described in U. S. 1,480,640; C. A. 18, 909) are combined with dyes of the triarylmethane series (e. g., dyes as described in U. S. 1,387,596; C. A. 15, 4053) by heating the components together. The resulting dyes are as easily sol. as the azo dyes contg. Cr used as starting materials and yield on wool in an acid bath very level shades of good brightness.

Halogenated naphthazine dyes. W. HERZBERG, G. HOPPE and H. OILENDORF. U. S. 1,538,400, May 19, 1925. Dyes producing golden yellow colors on cotton are produced by introducing 4 atoms or less of halogen (e. g., Br) into compds. such as those of the type made by fusing 1,1',2,2'-dinaphthazine-8,8'-disulfonic acid with alkali.

Indophenol sulfur dyes. A. GORSCHKE. U. S. 1,534,518, Apr. 21, 1925. Dyes contg. S are obtained by treating with alkali polysulfides the indophenols which may be prepd. by condensation of nitrosophenols with diphenylamine derivs. having, on the one hand, at least 1 CH₃ group in *o*-position to the NH group, and, on the other hand, at least 1 free *p*-position to the same NH group, e. g., *o*-tolylphenylamine or *o,o'*-ditolylamine. These dyes form dark blue powders and dye cotton blue.

Sulfurized dyes. O. SPENGLER. U. S. 1,536,731, May 5, 1925. Dyes producing fast violet shades on cotton are obtained by sulfurizing 4-phenylamino-3,5-dichloro-4'-hydroxydiphenylamine, 1(*p*-methoxyphenylamino)-3,5 dichloro-4'-hydroxydiphenylamine or similar compds.

Bluish sulfurized indophenol-benzidine dyes. I. HAAS. U. S. 1,565,736, Dec. 15. Leuco derivs. of the indophenols obtained by condensation of nitrosophenols with carbazole in the presence of benzidine are sulfurized to produce dyes giving fast blue shades.

Cyanuric intermediates for dye manufacture. H. FRITZSCHE and P. SCHAEDEL. U. S. 1,551,095, Aug. 25, 1925. Cyanuric halides are condensed with α -naphthol to form nuclear condensation products for dye manuf. AlCl₃ or H₂SO₄ may be used as condensing agents, with or without inert solvents or diluents such as CS₂, petroleum ether, C₂H₅Cl, or PhNO₂. Numerous examples are given.

Benzanthrone derivatives. A. LÜTTRINGHAUS, H. WOLFF and H. NERESHEIMER. U. S. 1,564,423, Dec. 8. Condensation products are formed by treating a benzanthrone compd. or benzanthrone itself with an alk. condensing agent, e. g., KOH, at temps. below those at which dyes are formed. The products are *dye intermediates*.

Benzanthrone derivatives. G. KALISHER, R. MÜLLER and F. FRISTER. U. S. 1,565,229, Dec. 8. α -Naphthaleneazobenzene-*m*-carboxylic acid or its substitution products are reduced to hydrazo compds. and the latter, in acid soln., are transformed into 4,4'-diaminonaphthylphenyl-2'-carboxylic acids and these are condensed with acid condensing agents to produce benzanthrone derivs. These products constitute intermediates for production of dyes of the violanthrone and isoviolanthrone series. Several examples are given.

Dye intermediate of the anthraquinone series. G. KRÄNZLEIN, M. CORELL and R. SEDLMAYER. U. S. 1,564,584, Dec. 8. Compds. corresponding to 3,4,8,9-dibenzo-pyrenequinone (which may be substituted in various ways) are prepd. by condensation of benzanthrone with benzoyl chloride or other aromatic acid chloride.

Aromatic derivatives of cyanuric chloride (dye intermediates). H. FRITZSCHE and P. SCHAEDEL. U. S. 1,566,742, Dec. 22. New nuclear condensation products are obtained by causing 1-2 mol. proportions of α -naphthol and 2-1 mol. proportions of any other aromatic compd., adapted for yielding nuclear condensation products, to react, in any desired sequence, on one mol. proportion of a cyanuric halide. Details are given for the production of 2,4-di-*p*-hydroxynaphthyl-6-xylyl-1,3,5-triazine, 2-*p*-hydroxynaphthyl-4,6-di- β -hydroxynaphthyl-1,3,5-triazine, 2,4-di-*p*-hydroxynaphthyl-6-resoreyl-1,3,5-triazine, 2,4-di-*p*-hydroxynaphthyl-6- β -hydroxynaphthyl-1,3,5-triazine, 2,4-di-*p*-hydroxynaphthyl-6- β -methoxynaphthyl-1,3,5-triazine and 2,4-di-*p*-hydroxynaphthyl-6-anthracene-1,3,5-triazine. These compds. are in general of red or reddish color.

1-Aryl-5-pyrazolones. H. FRITZSCHE and E. REBER. U. S. 1,534,512, Apr. 21, 1925. Dye intermediates are formed by diazotization and reduction of 3-aminobenzene-1-sulfamide, 3-aminobenzene-4-methylsulfamide or other amide of a sulfonic acid of a primary aromatic amine, and condensing the hydrazone thus obtained with acetoacetic ester or oxalacetic ester or other derivs. of ketonic acids. Numerous examples are given.

Sulfaminoazo compounds. K. HEUSNER and M. SIMON. U. S. 1,532,627, April 7, 1925. The α -naphthylsulfaminic acid described by Piria (*Ann.* 78, 31 *et. seq.* (1851)) as a thionaphthamic acid is combined with various diazo compds. and the entry of the

diazo group occurs almost quantitatively in the *p*-position to the sulfamino group. Dyes are obtained in better yields than from α -naphthylamine.

Dyeing black silk piece goods. J. SEYER. U. S. 1,565,515, Dec. 15. See Brit. 219,995 (C. A. 19, 736).

Dyeing silk piece goods. J. SEYER. U. S. 1,565,516, Dec. 15. Goods weighted in the skein with a Sn compd. are treated with a Na_2HPO_4 soln. contg. a direct dye.

Dye vat and dye liquor circulating devices. J. H. THOMPSON. U. S. 1,565,037, Dec. 8.

Stencil dyeing of furs and pelts. H. M. BECHER. U. S. 1,566,066, Dec. 15.

Apparatus for dyeing wound yarns on spindles. JOHN, THOMAS and JOSEPH BRANDWOOD. U. S. 1,562,736, Nov. 24.

Apparatus for handling skeins or hanks in dyeing rooms. B. MAYOUX. U. S. 1,532,707, Apr. 7, 1925.

Apparatus for testing fastness of colors by exposure to ultra-violet rays. L. J. BUTTOLPH. U. S. 1,558,786, Oct. 27.

Artificial silk. H. DREYFUS. U. S. 1,566,384, Dec. 22. In forming artificial silk threads and filaments from cellulose derivs. such as cellulose acetate, spinning solns. are employed contg. acetone or other volatile solvent and also contg. a liquid of higher b. p. such as acetone-alc., acetyl acetone or diacetone-alc. which is a solvent of the cellulose deriv. (the use of toxic Cl derivs. being avoided), in order to regulate the solidification of the filaments and facilitate the spinning of fine deniers. Cf. C. A. 19, 404.

Recovering silk from silk crop waste. V. PIANA. U. S. 1,565,196, Dec. 8. Silk crop waste is treated in a closed chamber heated from the outside to a temp. at which the vegetable matter usually mixed with silk crop waste is rendered dry and friable. The waste is then subjected to a crushing operation and the silk is sepd. from the pulverized vegetable matter.

Weighting silk. A. PEPPER. U. S. 1,565,390, Dec. 15. Fabric is treated with SnCl_4 , then washed and treated with a soln. of Na phosphate, again washed, treated with HOAc soln., washed with cold H_2O , treated with a soln. of Pb acetate, washed and treated with a cold soln. of Na phosphate.

Viscose solutions. E. S. HUMBOLDT. U. S. 1,562,885, Nov. 24. A viscose soln. is ripened by the action of heat and the ripening is arrested by the application of a cold pptg. bath followed by redissolving of the ppt.

Fabric impervious to petroleum hydrocarbon vapors. R. E. WILSON and E. P. BROWN. U. S. 1,566,943, Dec. 22. A continuous coating of a mixt. of glue and glycerol is applied to a textile fabric and dusted with finely divided talc or other inert substance.

Linen-like finish on cotton fabrics. E. R. CLARK. U. S. 1,564,943, Dec. 8. Cotton fabric is impregnated with a viscose soln. of low alkyl., the excess soln. is removed and the cellulose is pptd. from the viscose on the fabric by the use of a pptg. bath such as dil. H_2SO_4 .

Waterproofing fibrous sheet material. T. W. MORSE. U. S. 1,563,642, Dec. 1. Immediately after forming a sheet from fibrous material on a forming cylinder an emulsion of asphalt or similar waterproofing material is deposited on the surface of the sheet and the coating and sheeted stock are united by vacuum action.

Moth-proofing wool, furs, etc. W. LOMMEL and H. MÜNZEL. U. S. 1,562,510, Nov. 24. The material is treated with pyrazolone, ethylidenephénylcarboxylic-acid-ethyl-ester hydrazone, triphenylguanidine or other compd. of the "general formula $-\text{N}(\text{R})-\text{X}:\text{Y}$, in which R represents H or a radical, X represents N or C and Y represents N, C or a nuclear radical." C_6H_6 may be used as a solvent.

Waterproofing straw hats, etc. C. J. KUNTZ and J. SIMONS. U. S. 1,566,798, Dec. 22. A pliable adhesive solid waterproofing coating is formed from nitrocellulose and sandarach gum.

Bleached and dyed furs. H. STERN, W. E. AUSTIN and I. LIEBOWITZ. U. S. 1,564,378, Dec. 8. Furs are treated with protective agents such as dil. FeSO_4 soln. to prevent harmful action by bleaching agents such as H_2O_2 .

Centrifugal machine for treating textile materials on perforated drums with liquids or gases. H. WOLFER. U. S. 1,564,503, Dec. 8.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Use of tunny oil (*Thynnus pelamys*) in the paint industry. PÉRARD AND GRIMAUD. *Chimie et industrie Special No.*, 424-6 (Sept., 1925).—A com. oil of known purity had the following consts: d_{4}^{20} 0.9338, n_D^{20} 1.4825, acidity (as oleic) 1.351%, sapon no 183, Hehner no. 94.8, sol. acids (as butyric) 0.58%, Reichert-Meissl Volny no 0.77, I no. 174.83, Ac no. 13.7, unsaponifiable 0.58%, mean mol wt. of total fatty acids 314.48, I no. of fatty acids 180.44, m p. of fatty acids 29.8°; solid fatty acids 31.0%, mean mol wt 228.31, I no. 0.7, m p 37.3°; liquid fatty acids 69.0%, mean mol wt 396.82, I no. 187.98, Ac no 88.7. The Livache test (1.0192 g Pb, 0.5788 g oil) gave a max. increase in wt. of 15.35% in 16 days, compared with 12% in 16 days for linseed oil. On exposure to air and light tunny and linseed oils gave the following results: gain in 150 days 10.60, 5.61%; wrinkles appeared in 28 and 123 days; solidified in 40 and 150 days, resp. Comparative painting tests with tunny and linseed oils showed no difference between the two.

A. PAPINEAU-COUTURE

The size of pigment particles. R. AUDUBERT AND H. RABATÉ. *Chimie et industrie Special No.*, 486-93 (Sept., 1925).—A discussion of the effects of the degree of subdivision of pigments on sp. surface, apparent d., cond., color of mixts., proportion of vehicle required, phys. stability of the paints, ease of application, covering power, thickness of the paint film, drying, adhesive power, hardness, impermeability, durability and optical properties of the dry paints.

A. PAPINEAU-COUTURE

The chemist his place in the varnish factory. L. HAMBRICK. *Can. Chem. Met.* 9, 240 2 (1925).

E. H.

Abietic acid. G. DUPONT AND R. UZAC. *Chimie et industrie Special No.*, 482-3 (Sept., 1925). Abietic acid was prepd. by boiling a soln. of rosin in alc. with HCl, and recrystg. repeatedly from alc. Rosins obtained from gum turpentine of *Pinus maritimus*, Aleppo pine, Austrian black pine (*P. laricio*), *P. longifolia* and *P. pinca* (all of known purity) gave practically identical yields of the same abietic acid, m 173°, $[\alpha]_D^{25}$ about -105°, rotatory dispersion about 1.156. Abietic acid cannot exist in rosin in the form of anhydride because rosin can be converted into abietic acid in the dry way and because rosin does not give a ppt. of the acid soap $3(C_{20}H_{30}O_2) \cdot C_{20}H_{30}O_2 \cdot Na$ as does abietic acid when treated with one-quarter of the NaOH required for complete neutralization. D. has shown (*C. A.* 15, 3093) that abietic acid is the final product of the isomerization at high temp. or under the action of strong acids of the acids constituting the gum turpentine obtained from various pines. This isomerization takes place in 2 or more stages and rosin consists of these intermediate acids, which are insomorphous with abietic acid. Rosin is, therefore, considered to be a reciprocal soln. of these acids, quite comparable to a glass which is a reciprocal soln. of isomorphous silicates. Com. isomerization can be obtained by passing a slow current of HCl gas through fused rosin at 150° for 15 min., giving a rather crude product which can be purified by recrystn. from alc. It can also be obtained by boiling an alcoholic rosin soln. with concd. HCl, neutralizing the HCl and one-quarter of the abietic acid, sepg. the liquor from the pptd. acid soap and decomp. the latter with a strong acid.

A. PAPINEAU-COUTURE

Rosin esters. P. F. LAFON. *Chimie et industrie Special No.*, 468-73 (Sept., 1925) --- Rosin cannot be used as such in paints with basic pigments because of its acid nature; but it can be used if the acid function has been blocked, by forming either metallic salts or esters. Fused metallic resinate are still too acid for use in paints and the prepn. of neutral pptd. resinates is complicated and expensive. A suitable glycerol ester is prepd. by gradually heating 100 kg. of rosin, 11 kg. glycerol and 0.5 kg. slaked lime in an Al container to about 290°. About 100 kg. of ester is obtained, with a color equiv. to water-white rosin, acidity of about 5%, harder and more brittle than rosin and with higher m p. than the latter. It can be sold at about the same price as the lower grades of copals, and possesses the advantage over gums that it is completely and easily sol. in the usual varnish solvents. The Ca resinate formed during heating catalyzes esterification. Zn resinate is a more active catalyzer, but gives an appreciable greenish color. Without catalyzer, L. could not obtain esters with less than 12.5% acidity.

A. PAPINEAU-COUTURE

Emulsion films (HOLMES) 2.

Paint. H. J. DUFFEY. U. S. 1,566,957, Dec. 22. A paint adapted for use on

wood or metal comprises a filler and pigment and waste used lubricating oil such as is obtained from engine crank cases.

Automobile body finish. W. Y. TIME. U. S. 1,565,122, Dec. 8. A priming coat comprises red lead mixed with 25% of coach japan and 50% of raw linseed oil. A second coat comprises white lead in oil mixed with 70% of boiled linseed oil and sanded. A third coat comprises white lead in oil mixed with 50% of boiled linseed oil and 50% of finishing varnish and also sanded.

Lithopone. J. L. MITCHELL. U. S. 1,565,185, Dec. 8. Lithopone is quenched in a soln. of Ba sulfide or other sol. alk. earth salt to form a coating and this coating is rendered insol. e. g., by calcining to convert the Ba sulfide into BaSO₄.

Ink. C. L. CUNNINGHAM. U. S. 1,562,544, Nov. 24. A penetrative ink adapted for use on shellac or other varnish or paint is formed from alc., diethyl phthalate, and Et ester such as Et lactate or oxalate which acts as a solvent for softening and penetrating varnish, paint or other hardened non-hygroscopic coating and coloring matter.

Transfer ink. E. GORCY. U. S. 1,564,234, Dec. 8. An ink adapted to be transferred under heat comprises mutton fat 49, black soap 14 parts and coloring substances.

Polish for varnished surfaces. B. BUHR. U. S. 1,566,576, Dec. 22. A mixt. of boiled linseed oil 16, gasoline 10 and skunk oil 2 parts

Vulcanizing oils in situ as varnishes. J. H. VAN DER MEULEN. U. S. 1,566,785, Dec. 22. Leather, artificial leather or other materials are coated with linseed oil or other vulcanizable oil and the latter is then vulcanized *in situ* by the action of S chloride vapor.

Acid-resistant shellac substitute. J. R. KUHN. U. S. 1,564,002, Dec. 1. Meta-para-cresol is treated with about 1½ times its wt. of S chloride in the presence of a hydrocarbon diluent such as C₆H₆ or toluene to form a resinous substance in soln. and the soln. is blown with heated air at a temp. below 156° (preferably about 150°) to remove the diluent and HCl. The deodorized resinous product is dissolved in an alc. solvent and a small quantity of H₃PO₄ is added to change the soln. from a brown to a yellow color.

Stove polish. M. LEVIN. U. S. 1,563,421, Dec. 1. Resin is dissolved in cold mineral oil, pulverized graphite and carbon black or other pigment is stirred into the soln. and more oil is then added to give the desired consistency.

Artificial resin compositions from naphthenates. F. ZERNIK. U. S. 1,537,572, May 12. Compns. adapted for prep. lacquers and for other purposes are obtained from naphthenates of Mg, Ca, Al, Zn, etc., mixed with each other or with other resinous substances. The naphthenic acid used as starting material is purified by distn. or otherwise and, when drying is required, is dried at temps. not exceeding 160° (to avoid discoloration).

Preventing sticking of resinous materials to molds. H. M. WEBER. U. S. 1,558,440, Oct. 20. A dusting powder comprising Al palmitate, Zn stearate or other metallic soap is applied to molds in which resinous substances such as synthetic products from PhOH and CH₂O are to be molded.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL.

Annual review in the field of fats, oils and waxes for 1923. W. HERBIG. *Z. deut. Oel-Fett-Ind.* **44**, 527-9, 544-5, 557, 572-3, 582-3, 594-6, 606-7, 620-2, 632-3, 643-5, 655-7(1924); **45**, 2-3, 18-20, 43-4, 53-5, 67, 91-3, 107-8, 123, 136-8, 153-4, 164-5, 192, 208, 219-20, 248-9, 264-6, 276-7, 290-1, 334-5, 347-8, 360-2, 374-5, 387-9, 402-3, 418-20, 430-2, 448-9, 479-80 496-8(1925).—A review under the following captions: A. Physical behavior. B. Chem. behavior. Constants. C. Analysis. D. Special analytical investigations of fats and oils. E. Investigations of individual old and new vegetable oils and fats. F. Investigations of animal fats and waxes. G₁. Technical production and applications. G₂. Refining fats. G₃. Splitting fats. G₄. Soap manufacture. G₅. Special products. Several hundred references to the literature are given in footnotes. P. ESCHER

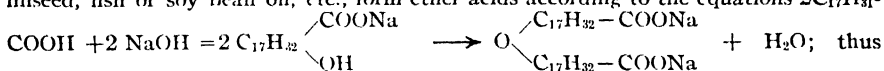

The application of the rapid iodine number method to fish oils. B. M. MARGOSCHES, I. FRIEDMANN AND K. FUCHS. *Z. deut. Oel-Fett-Ind.* **45**, 605-6(1925).—The rapid method for detg. I no., developed by the authors, gave erratic results when used for fish oils. An excess of at least 70% I soln. is necessary to obtain normal Hübl values in 5 min. With very dark oils 2-3 cc. of CCl₄ is added just before the titration

is finished. Exposure to the I soln. for longer than 5 min. leads to "super-I-values."

P. ESCHER

Method of separating saponifiable fats and oils from unsaponifiable mineral oils.

C. STIEPEL. *Seifensieder Ztg.* **52**, 949-59(1925).—The German pat. 293,167 by S. is now in industrial use. Recovered mixts. of vegetable or animal oils with mineral oils are first saponified fully with a metallic base; ZnO is excluded since its soap breaks down at high temp., the mixts. are then made anhyd. and finally distd. at 300° or above by means of indifferent vapors to sep. the mineral oil from the soaps. The resulting glycerol distills over simultaneously without essential decompn. Next the residual soap is decomposed with acid and the liberated dark fatty acids are redistd., furnishing light-colored acids of 96-97% purity. At this high temp. the highly unsatd. acids from linseed, fish or soy bean oil, etc., form ether acids according to the equations $2C_{17}H_{31}$

they lose their original character and yield acids with the following consts.: sapon. no. 193-206, acid no. 197-203, I no. 83-9

P. ESCHER

Determination of unsaponifiable matter in distillate fats. J. GROSSER. *Seifensieder Ztg.* **52**, 853-4(1925).—Attention is called to the presence of volatile products of decompn. in distd. fatty acids and in overheated fats, which in the analytical detn. of unsapon. matter are partly lost if the final drying takes place at 100°; G. dries at 60°, using gasoline of corresponding b. p. for extrn.

P. ESCHER

Deodorization of fish oils and similar fats. J. GROSSER. *Z. deut. Oel-Fett-Ind.* **45**, 622-4, 639-40(1925).—For high-grade fish oils the deodorization by hydrogenation is complete. For lower grades deodorizing the sepd. acids by means of concd. H_2SO_4 is in general use. High losses in the form of pitch residues constitute the drawback; while a detn. of the hexabromide no. gives a measure of the loss to be expected because the highly unsatd. acids are the carriers of fish odor and are removed by the H_2SO_4 . The simultaneous destruction of less satd. acids may be great, either by the use of too much acid, too high a temp., or too long a treatment; the presence of hydroxy acids also increases the loss. It is not known whether the acids with 3 or 4 double C bonds are simply removed or whether in the reaction they are converted into less satd. acids. Sandberg's method of using 10-15% H_2SO_4 at 40° avoids the undesirable side reactions of higher temps., but does not remove the highly unsatd. acids completely and the process has not come into general use.

P. ESCHER

Characteristics of fish and allied oils. A. R. LANGE. *Ind. Eng. Chem.* **18**, 9 (1926).—Phys. and chem. characteristics on a season's production of fish and allied oils are given.

E. SCHERUBEL

Tall oil. DUESBERG. *Seifensieder-Ztg.* **52**, 873-4(1925).—The following consts. for tall oil are given: source, Finland; color, orange with green fluorescence; liquid at 17°; acid no. 164.4; sapon. no. 174.9; unsapon. matter 6.05%; total org. acids 91.3, of which there are aliphatic acids 58.0% and rosin acids 32.0%. *Aliphatic acids*: I no. 100.0; sapon. no. 187.0; mean mol. wt. 298.7. *Rosin acids*: sapon. no. 169.8; mean mol. wt. 329.9. Analysis of purified tall oil: color light yellowish red; solidifies at 0°; acid no. 154.6, corresponding to 77.7% calcd. as oleic acid; sapon. no. 173.4; H_2O 0.32%; ash 0.08%; unsapon. matter 5.4%; total fatty acids 93.4%; rosin acid 37.1%.

P. ESCHER

The determination of the acid and lime stability of sulfonated oils. W. HERBIG AND H. SEYFERTH. *Z. deut. Oil-Fett-Ind.* **45**, 526-7, 548-52, 561-3, 574-6(1925).—The detailed expts. are given which led to the development of the method described in C. A. **17**, 220, and the method itself is modified by first neutralizing the soln. toward methyl orange prior to the titration for turbidity.

P. ESCHER

Continuous press for the treatment of oil seeds. ANDRÉ DUPIRE. *Chimie et industrie Special No.*, 428-30(Sept., 1925).—The chief drawback of the continuous screw press is that it gives a dark oil cake due to the heat developed during pressing, which in turn affects the quality of the oil. This has been overcome by a preliminary drying in a current of air heated to 70-80° and by cooling the rotating parts as much as possible by circulation of cold water through the shaft. This is claimed to increase the yield of oil and decrease the proportion of foots, and the preliminary air-drying carries off light husks.

A. PAPINEAU-COUTURE

Factors influencing variations in the physical and chemical constants of a given fat. S. WOLFF. *Chimie et industrie Special No.*, 431-2(Sept., 1925).—A brief discussion of the effects of climate, nature of soil and of feed, age of the animal or maturity of the grease, action of hydrolysis and oxidizing agents on animal fats.

A. P.-C.

Palm oil in French West Africa. PAUL AMMANN. *Chimie et industrie Special No.*, 433-4 (Sept., 1925).—Brief outline of possible improvements in the production of palm oil by the natives. A. PAPINEAU-COUTURE

Determination of oil in peanut oil cake. G. BRÉDON AND A. DUBOIS. *Chimie et industrie Special No.*, 437 (Sept., 1925).—The method proposed consists in detg. the I no. *via* Hübl, with Et_2O instead of CHCl_3 as solvent. A blank should be run on the extd. cake. The detn. can be run in about 2 hrs., it gives results agreeing to within a few tenths % with the ordinary extn. method, and is considered valuable for works control. It is applicable to other cakes, except those of the coprah group which have too low I nos. A. PAPINEAU-COUTURE

Autoclave-saponification and autoclaving methods. C. STIEPEL. *Z. deut. Oel-Fett-Ind.* 45, 637-9 (1925).—In 1844 Schönwald published in his "Reisetaschenbuch" an account of expts. in England on boiling soap in autoclaves for 2-3 hrs. and S. supposes that the inability of visually following the operation has probably caused abandonment of the process, but he considers success possible with present day facilities. Soaps of unsatd. acids, when exposed in alk. soln. to higher temps. and pressures, have OH groups joined at their double bonds: Na linolate with an I no. of 174 for its acid has its lowered to 83.4 after 3 hrs. in an autoclave at 270° . A table is given showing the effect of time, temp. and concn. on soap solus. which are autoclaved. References are made to the following Ger. patents on soap autoclaving: 349,593, 365,271 and 287,660 P. ESCHER

Fundamental principles of detergent action revealed by the graphite test. R. M. CHAPIN. *Ind. Eng. Chem.* 17, 1187-91 (1925).—The graphite test for detergent efficiency is shown to be valuable for investigating the fundamental principles of deflocculation and detergency. Concn.-temp. curves of various soaps are presented which afford data for a more complete theory of deflocculation and detergency than heretofore established. The data and theory cover the effect of (a) crystalloidal soap, (b) colloidal soap, (c) free fatty acids, (d) acid soap, (e) nature of fatty acid, and (f) nature of alkali. In particular it is shown that the colloidal fraction of a soap is inert as a detergent at equil. F. SCHERUBEL

Detergents and soaps. E. A. F. *Parfumerie moderne* 18, 255-60 (1925).—Brief historical notes on the development of detergents and soaps from Biblical times to the present day. A. PAPINEAU-COUTURE

The use of artificial fatty acid esters as textile fats for textiles (WEIHWART) 25.

Apparatus for filtering sugar solutions, etc. W. HOEHN. U. S. 1,564,351, Dec. 8. **Soluble-starch product.** R. HALLER. U. S. 1,564,955, Dec. 8. By reaction of a chloramide, *e. g.*, *p*-toluene sulfochloramide, upon starch a product is obtained which is sol. in hot H₂O.

Treating starch with hydrochloric acid or other modifying reagents. P. A. SINGER. U. S. 1,564,979, Dec. 8. A hot liquid spray contg. starch and a small quantity of aq. HCl is projected into a highly heated reaction chamber where modification of the starch is effected while the minute starch particles are in suspension.

29—LEATHER AND GLUE

ALLEN ROGERS

General principles of leather manufacture. LOUIS MEUNIER. *Gerber* 51, 181-3 (1925).—An address. H. B. MERRILL

Sole leather manufacture. Slow tannage with fir bark. DOHOEGNE. *Halle aux Cuirs* 1925, 309-11.—A description of the process as carried out in Czechoslovakia. H. B. MERRILL

British section chrome leather analysis subcommittee. The control of chrome liquors in the one-bath chrome tanning process. D. WOODROFFE. *J. Intern. Soc. Leather Trades' Chem.* 9, 480-5(1925).—The basicity value of a chrome liquor is not a reliable guide as to its tanning properties nor does this value bear any definite relation to the pptn. figure. The *p*_H value seems to be the most likely variable controlling tanning properties. J. A. WILSON

Preparation of leather for analysis. L. BALDERSTON, *et al.* *J. Am. Leather Chem. Assoc.* 20, 583-9(1925).—General discussion. J. A. WILSON

Machine for preparing leather samples for analysis. A. C. ORTHMANN. *J. Am. Leather Chem. Assoc.* 20, 579-83(1925).—Working drawings. J. A. WILSON

Contribution to the study of the estimation of fat and water solubles in leather. A. COLIN-RUSS. *J. Intern. Soc. Leather Trades' Chem.* 9, 455-78(1925).—Attempts were made to devise methods for detg. the amts. of fat and water solubles in leather without having to make a complete extn. In making successive extns. with fat solvent or with water, when the leather had reached equil. with the solvent, it was assumed that the ratio of sol. material in the external solvent to that retained by the leather was const. The value of the const. was assumed to be characteristic of the sample of leather, but independent of the dilution. The assumption seemed to be verified in the fat extns., but complicated in the extns. with water by the hydrolysis of the leather. J. A. WILSON

Destructive action of sulfuric and hydrochloric acids upon leathers. J. A. WILSON. *Ind. Eng. Chem.* 18, 47-50(1926).—In contact with acid solns. of increasing strength, chrome leather is destroyed much more rapidly than vegetable-tanned leather. Thin sheets of leather can be made by coating the surface of chrome leather with vegetable tannin and then soaking it in 6 N H₂SO₄ which will dissolve away all except the tannin-coated film. Chrome leather has a greater capacity for combining with acid than vegetable-tanned leather. It is only the volatility of HCl that makes its presence in leather less harmful than H₂SO₄. Chrome leather is easily destroyed by either HCl

or H_2SO_4 , but more quickly by HCl in solns. stronger than 3 N and more quickly by H_2SO_4 in solns. weaker than 3 N . J. A. WILSON

The swell and shrink of upper leathers. J. A. WILSON. *Hide & Leather* 71, No. 1, 15(1926).—A table is given which shows the area changes with relative humidity of calf, kid and side leathers. J. A. WILSON

Comparative resilience of leather and rubber heels. J. A. WILSON. *J. Am. Leather Chem. Assoc.* 20, 576-9(1925).—The resilience of leather is measured by the percentage rebound of a brass plunger dropped from a definite height onto the leather backed by a resilient maple block. In a series of tests on com. healing materials, oak-tanned sole leather was most resilient (37-39%), rubber heels intermediate (20-37%), and chrome sole least resilient (17-19%). J. A. WILSON

Tests with various hide powders using a buffer solution of $p_{\text{H}} = 4.6$. J. GORDON PARKER AND J. T. TERRELL. *J. Intern. Soc. Leather Trades' Chem.* 9, 479-80(1925).—Certain discrepancies in tannin detn. found when hide powder from different sources were used can be eliminated by pretreating all hide powder with an acetate buffer soln. of $p_{\text{H}} 4.6$. J. A. WILSON

The definition of swelling and plumping of hide. P. PAWLOWITSCH. *Collegium* 1925, 583-6.—A review. I. D. CLARKE

Bacteriology of calfskin soaking. G. D. McLAUGHLIN, et al. *J. Am. Leather Chem. Assoc.* 20, 597-600(1925); cf. *C. A.* 19, 2572.—Discussion. J. A. WILSON

Some principles of depilation. G. D. McLAUGHLIN, et al. *J. Am. Leather Chem. Assoc.* 20, 590-6(1925); cf. *C. A.* 19, 2279.—Discussion. J. A. WILSON

Colloid chemistry in tanning. W. D. BANCROFT. *J. Am. Leather Chem. Assoc.* 20, 565-73(1925).—An address. J. A. WILSON

Dyeing and tanning in relation to one another. HUGO KÜHL. *Ledertech. Rundschau* 17, 153-5(1925).—Dyeing and tanning are discussed as colloidal adsorption processes. I. D. CLARKE

Report of the international committee on quantitative analysis of tanning materials. G. G. HUGONIN. *Chimie et industrie Special No.*, 513-8(Sept., 1925); cf. *C. A.* 18, 3290. Collaborative results on galls, sumach, natural and solubilized quebracho, wattle, mangrove and chestnut show that: (1) the present official method for detn. of insol. in tanning exts. by filtration through a Berkefeld filter is subject to considerable error and is not rational because substances which are of value for tanning are filtered out; (2) the sedimentation (2 hrs.) and centrifuging (20 min.) methods give consistent and practically identical results, which are lower than those by the Berkefeld filter, centrifuging being preferable because it is quicker; (3) the sedimentation and centrifuge tubes should be stoppered and the latter opened only after cooling to room temp.; (4) acidification greatly increases the insol. in natural quebracho; (5) addn. of 100 cc. of 0.01 N HCl per l. of soln. gives a p_{H} of approx. 3, except with solubilized quebracho (3.4-3.6) and mangrove (1.6-5); (6) the p_{H} of the detanned ext. is in most cases appreciably higher than the isoelec. point of hide powder ($p_{\text{H}} 4.8$), showing that hide powder No. B-11 contains an amount of alkali (probably in the form of Ca collagenate) equiv. to 16-18 cc. of 0.1 N NaOH per 6.5 g. of powder. Acidification of the soln. eliminates errors due to variations in the adsorption coeffs. of different lots of hide powder, and the increase in insol. sometimes caused by acidification is prevented by acidifying only the portion used for the detn. of tannins. A. PAPINEAU-COUTURE

Synthetic tannins: ultraviolet absorption spectra and color and precipitation reactions. A. DE LA BRUÈRE. *Chimie et industrie Special No.*, 519(Sept., 1925).—See *C. A.* 18, 3736. A. PAPINEAU-COUTURE

The fluorescence test; a new test for synthetic tannins in vegetable tanning extracts. O. GERNGROSS, N. BAN AND G. SANDOR. *Collegium* 1925, 565-72.—In ultraviolet light natural tannins in a diln. of 1:1000 show very slight or no fluorescence, while the important syntans all show a blue or violet fluorescence even in dilns. greater than 1:100,000. The fluorescence is not changed by small addns. of acid or alkali. The weak fluorescence of quebracho (*C. A.* 19, 3034) is removed by small amts. of acid or alkali. Although natural tannins decrease the fluorescence, 10-20% of syntan can almost always be detected in mixts. There was no relation between fluorescence and the Procter-Hirst test. In the discussion Noerr stated that vegetable leathers fast to light do not fluoresce while others do. I. D. CLARKE

Effect of vegetable tanning on the combination of collagen with acid. J. A. WILSON AND A. W. BEAR. *Ind. Eng. Chem.* 18, 84(1926).—An increasing degree of vegetable tannage causes a corresponding decrease in the capacity of collagen to combine with H_2SO_4 . J. A. WILSON

The astringency of vegetable tanning materials. E. CREDE. *J. Am. Leather*

Chem. Assoc. 20, 573-6(1925).—The astringency of a tan liquor is defined as the ratio of tannin as detd. by the Wilson-Kern method to tannin as detd. by the A. L. C. A. method. It is assumed that the difference in tannin values given by the 2 methods represents nonastringent tannin rather than nontannin. J. A. WILSON

Determination of free acid in vegetable-tanned leather. T. BLACKADDER, *et al.* *J. Am. Leather Chem. Assoc.* 20, 600-8(1925); cf. *C. A.* 19, 2279.—Discussion. J. A. WILSON

Tanning with quinone. H. SCHMIDT. *Ledertech. Rundschau* 17, 162-3(1925).—In quinone solns. buffered at different p_H values there was little or no tanning in 6 hrs. if the p_H was below 5. At p_H 5-12 the skins were well tanned and increased in wt. from 10 to 20%. With increasing time of tanning the max. increase in wt. changed from p_H 8-10 to p_H 5-6. Addn. of hydroquinone repressed tanning. I. D. CLARKE

Biology and prevention of salt stains. H. PERICAUD. *Cuir tech.* 14, 496-7(1925); cf. *C. A.* 19, 2423, 2885.—An address. H. B. MERRILL

Recent advances in methods of glue evaluation. W. L. JONES. *Mech. Eng.* 47, 1072-4(1925).—The difficulties of glue testing are discussed, also the standard methods of making viscosity and jelly-strength tests. Comparisons with so-called standard glues will disappear and glues will soon be described in terms of absolute viscosity in millipoises and jelly strength in g. The standard viscosity pipet, Bloom gelometer, and a curve showing the relation between viscosity and jelly strength of certain glues are given. W. H. BOYNTON

Glue for polishing metals (DIVINE) 4. Fluorescence of vegetable coloring materials (MEUNIER, BONNET) 3. Drying and conditioning leather (U. S. pat. 1,564,566) 13. Drying and oxidizing hides (U. S. pat. 1,564,565) 13. Rubber composition [as leather substitute] (U. S. pat. 1,566,247) (U. S. pat. 1,563,872) 30.

Leather for shoe soles. A. I. DUPREY. U. S. 1,562,624, Nov. 24. Shoe soles are cut from thoroughly tanned leather from which all uncombined tannin and extraneous matter have been removed. The cut soles are immersed in hot H_2O to expand the fiber of the leather and packed in boxes to permit the moisture to become evenly distributed throughout the material, then treated, under vacuum and heat, with a rubber soln. and with a 2% soln. of $S-Cl_2$, dried, washed and dried again.

Tanning composition. J. BREEDIS. U. S. 1,563,010, Nov. 24. Marrikino gum or other natural tanning material is heated with sulfite cellulose liquor in the presence of free alkali, e. g., aq. NaOH soln., until chem. reaction occurs, and the product is then acidified, to produce a substance which has better tanning properties than the constituents.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Maturation (slab) rubber. C. C. DAVIS. *Rubber Age* 18, 163(1925).—A summary and discussion of an article by Bruni and Levi (cf. *C. A.* 20, 303), including nearly all the original data. C. C. DAVIS

The spraying of rubber latex with protective colloids, particularly glue. W. CECIL DAVEY. *J. Soc. Chem. Ind.* 44, 515-7T(1925).—In expts. on the prepn. of sprayed rubber contg. glue, glue in twice its vol. of H_2O was added to NH_3 -preserved latex at 40° (1 part of glue to 3 parts of rubber) and the mixt. was sprayed in a chamber at 75°, yielding a fine white powder contg. about 1.5% H_2O . This rubber-glue mixt. (rubber 100 S 8, glue 10) was then milled with more rubber and S and the resulting mixt. (I) was cured and tested in comparison with a mixt. of the same compn. made by milling sprayed rubber, S and H_2O -softened glue (II). The stress-strain curves showed I to have lower elongations at given stresses and to have a higher breaking strength than II. Furthermore the rate of cure of I was slower than that of II, probably because of the formation of a retarding agent in the rubber-glue powder during storage. These rubber mixts. contg. glue deteriorated on standing and after several weeks they were less tough and had lower coeffs. of vulcanization than the same freshly prepd. mixts. vulcanized for the same periods. To make a suitable rubber-glue powder by spraying, at least 10% glue is necessary. Further expts. with other protective colloids showed that a powder is formed on spraying with 15% or more of casein or of Na lysal-

binat and with 5% of saponin, though the latter forms a powder which gradually coheres. Soaps have no influence. Vulcanized latex requires only about 0.5 as much protective colloid to form a powder on spraying. Thirty-nine references to patents and original articles are included.

C. C. DAVIS

An outstanding discovery in rubber compounding. MOORE AND MUNGER. *Rubber Age* 18, 164(1925).—*Catalpo* clay, a rubber compounding ingredient, differs from other clays in that it is prepd. by peptizing an ordinary clay. Because of the stability of the sol thus obtained, extraneous material may be removed to an extent not possible by the usual methods of mfg. clays. The extremely fine state of division obtained by this method renders the clay of unusual reinforcing value in rubber.

C. C. DAVIS

The Vultex process. Vulcanization of latex. PHILIP SCHIDROWITZ. *India Rubber-World* 73, 140 1(1925).—Vulcanized latex rubber (cf. Schidrowitz, C. A. 17, 1351, 2798, 3430; 18, 1589) is superior in its aging properties to vulcanized rubber prepd. by the dry process from ordinary raw rubber, whether this aging is artificial or natural. Not only has the former rubber the higher tensile strength when vulcanized, but it is much more resistant to sunlight and to a temp. of 150° F. than rubber vulcanized in the ordinary manner. This superiority holds true whether the rubbers are compared after hot or cold vulcanization. The unusual resistance to heat and light renders all kinds of goods prepd. from vulcanized latex rubber particularly suitable for use in the tropics.

C. C. DAVIS

Drying and oxidizing rubber (U. S. pat. 1,564,565) 13.

Rubber composition. B. W. ROTE. U. S. 1,563,872, Dec. 1. Cotton is satd. with a minor proportion of rubber soln., the solvent is removed and filling, pigment and vulcanizing substances are compressed into the dried mixt. of cotton and rubber and the compn. is vulcanized. It is adapted for use as a *leather substitute*.

Rubber composition. A. L. FREEDLANDER and W. G. GOODWIN. U. S. 1,565,995, Dec. 15. A compn. adapted for making molded articles comprises rubber 61³/₄ lbs., rosin oil 29 oz., (NH₄)HCO₃ 12 lbs., lime 49 oz., ethylidene-aniline 20 oz., S 18.4 lbs. and gas black 24 oz.

Rubber composition. J. M. GILLET. U. S. 1,566,247, Dec. 15. A relatively small quantity of cotton, asbestos or other fibrous material is mixed with a rubber solvent, a small quantity of rubber is dissolved in the solvent and pptd. on the fibers, SO₂ and H₂S are introduced, the fibers are strained out in matted formation and dried. The product is suitable for use as a *leather substitute* or *wall covering*.

Molding rubber articles. F. C. JONES. U. S. 1,564,310, Dec. 8. Layers of self-vulcanizing rubber-contg. solns. of different strength are poured into the space between an exterior mold and an interior core, and allowed to gel.

Incorporating rubber in non-aqueous liquids. J. M. WEISS. U. S. 1,563,410, Dec. 1. A colloidal aq. soln. of rubber (e. g., latex) is added to melted paraffin or other non-aq. liquid having a b. p. of at least 110°, the addn. being made at temps. of 110–150°.

Vulcanizing rubber. H. ORTME. U. S. 1,565,812, Dec. 15. Zn(OH)₂ is used to assist in the combination of S with rubber.

Vulcanizing rubber. S. M. CADWELL. U. S. 1,532,225, April 7, 1925. Various compds. including the group X:CSSC:X are used in vulcanization; e. g., an (O-alkyl deriv. of thiocarbonic acid disulfide, dibutoxy ester of carbonyl disulfide, thiobenzoyl disulfide, thiophenylacetyl disulfide, thioacetyl disulfide, acetyl disulfide, benzoyl disulfide, dibutylthiol ester of thiocarbonyl disulfide, dimethyldiphenylthiuram disulfide, diethyldiphenylthiuram disulfide and di-*p*-methylphenylenedimethylthiuram disulfide. Basic substances preferably are employed as accelerators with these vulcanizing materials. U. S. 1,532,226 specifies the use of compds. contg. the group CC(X)SS(X)CC, e. g., compds. in which "X" may be S and of the same type as those of the preceding pat. U. S. 1,532,227 specifies the use of Ba, Na, Pb, Zn, Li, Mg, Ca, NH₄, Fe, Hg or K alkylxanthates, alkoxy ester of K thiocarbonate, Zn dithiobenzoate, Pb dithiophenylacetate, Cd, Hg, Cu or K dithiobenzoate and a large number of similar compds. in vulcanization.

Vulcanizing rubber. S. M. CADWELL. U. S. 1,564,824, Dec. 8. Thiometal-formaldehyde or other thioaldehyde is used as an accelerator. U. S. 1,564,825 specifies the use of an alylated thioaldehyde, e. g., thiobenzaldehyde.

Superficial vulcanizing of rubber. J. B. DICKSON. U. S. 1,564,050, Dec. 1. A small quantity of a vulcanization accelerator is used with the surface portion only of

rubber articles to effect a relatively high degree of vulcanization at the surface and prevent adhesion to molds.

Apparatus for vulcanizing rubber in the form of tubing, etc. J. L. G. DYKES. U. S. 1,564,473, Dec. 8.

Rubber cement. B. P. TAYLOR. U. S. 1,566,566, Dec. 22. A compn adapted for cementing, coating, etc., is formed of latex, furfural and a "rubber stabilizer" such as a mixt of Cl derivs of $C_{10}H_8$.

Hard rubber boxes covered with wood impregnated with a phenolic condensation product. G. W. BULLEY. U. S. 1,566,815, Dec. 22. A box body of cellular hard rubber and an exterior covering of impregnated wood are united by vulcanization.

CHEMICAL ABSTRACTS

Vol. 20.

FEBRUARY 20, 1926

No. 4

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Barometric jet condensers. H. SIMONS. *Centr. Zuckerind.* **33**, 1450-1(1925) — A discussion of the advantages of counter-current operation over parallel current. For barometric counter current condensers, with H_2O at 10-15° and a vacuum of 650 mm., for an hourly condensation of (a) kg. steam the diam. of the shell in mm. should be (b): (a) 2000, (b) 600; (a) 3000, (b) 700; (a) 4000, (b) 800; (a) 5000, (b) 900; (a) 7500, (b) 1000; (a) 10,000, (b) 1100; (a) 12,500, (b) 1300; (a) 15,000, (b) 1400.

W. L. BADGER

The improved Twisselmann extraction apparatus with automatic recovery of the solvent. ANON. *Chem.-Ztg.* **49**, 902(1925), 1 cut — Cf. *C. A.* **18**, 1069. J. H. M.

A large-scale laboratory extractor. W. E. PATTERSON. *Can. Chem. Met.* **9**, 239-40(1925) — P. has designed a simple and ingenious device requiring only app. to be found in any well-equipped lab. No glass-blowing other than making bends in tubing is necessary. The material to be extd. is placed in a tubulated $CaCl_2$ jar, 2 ft. high, in which it is continuously exposed to the vapor of the solvent and subjected to an intermittent discharge of the liquid solvent. Sketch E. G. R. ARDAGH

Extraction apparatus with glass filter plates. P. H. PRAUSNITZ. *Z. angew. Chem.* **38**, 1014-5(1925) — Various types of extrn. app. are described, made by Schott (Jena) and having porous glass plates, made from pulverized glass partially sintered together, in place of thimbles of the usual types. Also in *Analyst* **50**, 440-4(1925).

WM. B. PLUMMER

Normal slide table for inorganic acids and lyes. ANON. *Chem.-Ztg.* **49**, 997(1925) — The table is so arranged that when a pointer is set at the sp. gr. of the soln. the % content is shown J. H. MOORE

The use of porcelain centrifugal tubes for chemical analysis. I. PINCUSSEN AND B. ARINSTEIN. *Chem.-Ztg.* **49**, 980-1(1925), 1 cut — Round-bottom porcelain tubes permit the ppts. to be ignited and weighed in the tubes, and are especially useful in biological work J. H. MOORE

High precision fractional distillation in the laboratory. W. A. PETERS, JR. AND THEODORE BAKER. *Ind. Eng. Chem.* **18**, 69-72(1926) — The still used was a modified Hempel type which is described in detail with illustrations. Sharper cuts were obtained than ever before in lab. stills. L. A. PRIDGEON

Calorimeter bombs of a different material. W. KOHEN. *Chem.-Ztg.* **49**, 935-6(1925) — A new steel, "Antinit," contg. 0.14% C, 0.496% Si, 16.5% Cr and a trace of Mn has been found very suitable for bombs. J. H. MOORE

A new micro-buret. OTTO DAEFERT. *Chem.-Ztg.* **49**, 917(1925), 1 cut. — Improvements in the I. Bang buret are described. J. H. MOORE

Calculation of the contents of partly filled horizontal cylinders. HACK. *Chem.-Ztg.* **49**, 936-7(1925), 3 cuts. — Cf. *C. A.* **18**, 1352. J. H. MOORE

Spiral springs of quartz. K. ŠLIUPAS. *Nature* **115**, 943(1925). — A spiral spring of quartz of four turns of about two cm. in diameter giving an extension of one cm. with 0.03 g. was made. FLORENCE N. SCHOTT

Spiral springs of quartz. C. V. BOYS. *Nature* **115**, 944(1925). — B. describes the production of a helical spring made of spun glass. FLORENCE N. SCHOTT

Spiral springs of quartz. H. G. SMITH. *Nature* **116**, 14-5(1925). — Spirals of fused quartz fibers of from 0.1 to 0.2 mm. diameter, having from 15 to 30 coils of diameter 0.5 to 1.5 cm., were prepd. in considerable number. These were used as "sorption balance" (cf. Bakr and McBain, *C. A.* **19**, 760). FLORENCE N. SCHOTT

Melting-point apparatus for several simultaneous determinations. M. SPETER. *Chem.-Ztg.* **49**, 981(1925), 1 cut. — The app. consists of a narrow glass tube, enlarged and perforated at the lower end, in which the thermometer stands. Around the top of the enlargement are several small holes through which the m. p. tubes pass, the lower

ends resting on the perforated bottom by the thermometer bulb. This tube is suspended in a larger tube contg. the heating liquid. J. H. MOORE

The decimal dropping bottle as a technical titration apparatus. C. BLACHER. *Chem.-Ztg.* **49**, 959-61(1925); 7 cuts.—The nipple of the "normal dropping bottle" is made of the proper size to give drops of 0.1 cc. of H_2O solns. Its advantages for rapid titrations, especially for the detn. of hardness in boiler feed H_2O , are enumerated, with 12 references (cf. Winter, *Apparatebau* 1923, 161). J. H. MOORE

New technical uses for the filter pump. E. A. VUILLEUMIER. *Ind. Eng. Chem.* **17**, 1278(1925).—The use of exhaust H_2O with its entrained air is recommended for purifying water contaminated with sewage, adding spreading power to insecticides applied with pumps, stirring precipitates, increasing the pleasurable sensation of a shower bath, improving the taste of drinking water, and increasing the amt. of dissolved O in aquariums. W. C. EBAUGH

Filter with continuous operation. K. W. GEISLER. *Z. Ver. deut. Ing.* **69**, 1437-41 (1925); 19 cuts.—Descriptions of the filters made by the Fullnerwerk, R. Wolf, and Fr. Gröppel. I. H. MOORE

A compressed air meter. WELISEK. *Physik. Z.* **26**, 811-6(1925).—See C. A. **19**, 3390. H. G.

A precise automatic pressure regulator. L. E. DAWSON. *J. Phys. Chem.* **29**, 1408-11(1925). The automatic pressure regulator previously described by D. (cf. C. A. **18**, 1069) has been modified to adapt it to the regulation of pressures above that of the atm. as well as those below atm. Pressures up to 50 cm. of Hg have been regulated to ± 0.1 mm. H_2O with this device. The regulator consists of some form of trap (a, j) connected by means of 2 vertical tubes of different diam. and lengths (b and c) with a reservoir of Hg (d). The regulator is connected to the tank in which the pressure is to be maintained const. through the tube (f or g), depending on whether the pressure is to be above or below atm. Its action depends upon the passage of a small, controlled quantity of air through the tube of small diam. (b). When enough Hg to uncover the lower end of the smaller tube has been forced through both tubes into the trap, air begins to pass through with the Hg. The passage of this air alters the pressure in the system. The quantity of air passing is then checked by a rise of the Hg in the reservoir (d), due to its return through the larger tube (c) under the changed pressure, thus more or less closing the end of the tube and controlling the quantity of air passing through the tube of smaller diameter. The range of pressure can be varied by altering the length of the 2 tubes, or, for small variations, by tilting the entire instrument. R. L. DODGE

Spray head for washing and absorption towers. P. MAHLO. *Gas u. Wasserfach* **68**, 791(1925).—A brief description of the app. manufd. by Adolf Ott Co. under Ger. 404,767; sketches are given. WM. B. PLUMMER

Economical pulverizing and mixing by the use of high-capacity pulverizing and mixing machines. HELMUT OSTREITER. *Chem.-Ztg.* **49**, 1018-20(1925). A general discussion, with special reference to H. Hildebrandt's new centrifugal ball mill. J. H. MOORE

The ultra-balance. FRIEDRICH HOLTZ. *Chem.-Ztg.* **49**, 916-7(1925); 1 cut.—Recent improvements are described. J. H. MOORE

New electric heater. ANON. *Chem.-Ztg.* **49**, 980(1925); 3 cuts.—The app. is for lab. use and is made by Strohleim & Co. J. H. MOORE

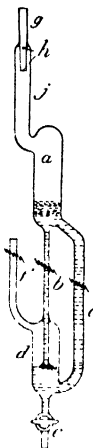

A new electric heating and fusing oven for high temperatures. H. SEIBERT. *Chem.-Ztg.* **49**, 1020(1925); 1 cut. J. H. MOORE

Almag ring mill. ANON. *Chem.-Ztg.* **49**, 997(1925). J. H. MOORE

The principles for the calculation of Venturi-meters. OTTO VON KÁLMÁN. *Siemens Z.* **5**, 473-8(1925).—A description of Venturi-meters from Die Wassermesser Fabrik der Siemens & Halske A. G., and the theory and calcus. for measuring of water, steam, gas and air. D. THUESSEN

A new potentiometer. E. MISLOWITZER. *Biochem. Z.* **159**, 68-71(1925).—A modified Poggendorff compensation potentiometer is described. This is a simple potentiometer which measures potential differences to about 0.7 mv. W. D. L.

Hydrogen-ion measurement with quinhydrone. A new double electrode in the form of a beaker. E. MISLOWITZER. *Biochem. Z.* **159**, 72-6(1925).—A vessel resembling a double-walled beaker is used to det. the p_H of solns. A soln. of known acidity is used as reference, and for it is substituted a quinhydrone soln. Many detns. of p_H may be made against the same reference electrode. W. D. L.

Measurement of the rate of flow of fluids by the rotameter. W. H. SIMMONS AND F. C. SUTTON. *Ind. Chemist* 1, 473-4(1925).—The rotameter consists of a top-shaped float contained in a tapered glass tube. The liquid to be measured in passing through the tapered tube lifts and spins the float. The spinning prevents the float touching the walls; hence there is no friction, and the height of the float adjusts itself to the flow which passes through the annular space between float and wall of tapered tube, which can be readily calibrated for any liquid. Temp. changes in liquids introduce scarcely any error, but for gases the densities (hence temp. and pressure) must be taken into account. Three types are illustrated and a no. of uses, present and proposed, discussed. E. G. R. ARDAGH

Use of methyl salicylate in a flowmeter. R. H. K. FOSTER. *Ind. Eng. Chem.* 18, 82(1925).—Certain properties of Me salicylate, such as its ability to dissolve oil or grease and its low vapor pressure, render it superior to H₂O, Hg or glycerol in a flowmeter. A design of flowmeter particularly suitable for this liquid is illustrated. C. C. DAVIS

Cylinder gage "Manoskop." ANON. *Chem.-Ztg.* 49, 979(1925); cf. C. A. 19, 1356. J. H. MOORE

Storage tank construction with the smallest quantity of material. STEIGLITZ. *Chem. App.* 12, 221 2, 229-31(1925); 6 cuts—Mathematical, with formulas for calcg. the size and material required for Fe tanks of given capacities. J. H. MOORE

Progress in the construction of tank cars. FR. BÜRK. *Chem. App.* 12, 209-11, 232 5(1925); 10 cuts. J. H. MOORE

Porcelain crucible (U. S. pat. 1,567,654) 19.

Acetylene generator. J. CHATWIN. Brit. 233,014, Jan. 24, 1924.

Thermometer. A. V. GROUPE. U. S. 1,567,321, Dec. 29.

Thermostat. L. J. GREENAWALT. U. S. 1,567,589, Dec. 29.

Thermostatic valve control device. F. W. ROBERTSHAW. U. S. 1,567,081, Dec. 29.

Radiation pyrometer. C. E. FOSTER. Brit. 233,606, Nov. 15, 1924.

Pressure gage for use with hydrogen. T. M. FINLEY. U. S. 1,567,794, Dec. 29.

Apparatus for measuring streams of steam, etc. A. GRAMBERG. U. S. 1,567,940, Dec. 29.

Distillation apparatus. K. S. NORDSTROEM. Swed. 58,555, April 15, 1925. Mech. features.

Distillation apparatus. ANDERS ELGESEM. Norw. 41,330, May 11, 1925.

Atomizer for liquids. AAGE NYROP. Danish 34,541, May 25, 1925.

Apparatus for circulating and standardizing solutions. J. F. WHITMAN. U. S. 1,568,117, Jan. 5. The app. is adapted for maintaining a uniform saline content in swimming tanks.

Apparatus for neutralizing and bleaching oils under a vacuum. E. BATAILLE. Brit. 233,345, April 30, 1924.

Filter. AKTIEBOLAGET SEPARATOR. Swed. 59,187, Aug. 5, 1925.

Filter with loose filtering material and concrete or similar foundation. W. PATERSON. Brit. 233,031, Jan. 29, 1924.

Oil filter. C. BREIER. U. S. 1,568,796, Jan. 5.

Filter for milk and other liquids. R. SELIGMAN. U. S. 1,568,001, Dec. 29.

Apparatus for producing hypochlorites or for other absorptions of gases in liquids. H. D. GOLDING, J. W. PRITCHARD and UNITED ALKALI CO., LTD. Brit. 233,490, March 21, 1924.

Apparatus for pulverizing gums. F. X. DOMENECH. Brit. 232,977, April 28, 1924.

Color-change indicator for warning of overheating of machine parts, etc. ROUSSEL ET CIE. Brit. 232,988, April 25, 1924.

Apparatus for cleaning centrifuge drums. AKTIEBOLAGET SEPARATOR. Swed. 59,475, Sept. 16, 1925.

Charging device for metallurgical and similar furnaces. F. THARALDSEN. Norw. 41,237, April 14, 1925. The feeding of a screw conveyor is regulated by shifting the feeding opening in the direction of the axis.

Rotary channel kiln combined with a smelting furnace of the electric or the blast-furnace type. PATENTAKTIEBOLAGET GROENDAL-RAMÉN. Swed. 59,401, Sept. 2, 1925.

Grid-shaped screen for X-ray apparatus. G. BUCKY. U. S. 1,567,833, Dec. 29.

Thermionic valves. EDISON SWAN ELECTRIC CO., LTD. Brit. 232,978, April 28,

1924. An incandescent cathode or auxiliary electrode is coated with Ca hydride or other compd. adapted to disintegrate gradually and produce ions which neutralize the space charge. Brit. 232,979 relates to activation of electrodes.

Thermionic valves. W. R. BULLIMORE. Brit. 233,375, Nov. 12, 1923. Filaments are formed with a base of nichrome wire, Mo, W or other refractory metal or alloy of high specific resistance and m. p. coated with a noble metal or alloy such as Pt or Pd. Details of applying the coating are given.

2—GENERAL AND PHYSICAL CHEMISTRY

GEORGE L. CLARK AND BRIAN MEAD

A pioneer investigator. S. W. PARR. *Ind. Eng. Chem.* **18**, 948 (1926). An appreciation of the life and work of Walter Rogers Johnson, born 1794, teacher, author, investigator, first secretary American Association for the Advancement of Science (1848), educationa reformer, etc. Special emphasis is laid upon a 606-page report on coal presented to the U. S. Govt. in 1844, in which analyses, evaporative tests, sp. gr., etc., of more than 40 kinds of coal are given in detail. W. C. EBAUGH

The discovery of benzene. J. F. THORPE. *Nature* **115**, 915-7 (1925).—A sketch of Faraday's scientific life in commemoration of his discovery of benzene in 1825. F. N. S.

The discovery of benzene. E. H. TRIPP. *Nature* **115**, 909 (1925).—A statement in Lunge's "Coal Tar and Ammonia" attributing the discovery of benzene to Schlenz, is refuted. Credit for discovery of benzene is due Faraday. FLORENCE N. SCHOTT

Revision of the atomic weight of germanium. II. **The analysis of germanium tetrabromide.** G. P. BAXTER AND W. C. COOPER, JR. *J. Phys. Chem.* **29**, 1361-78 (1925); cf. *C. A.* **18**, 2272. Ge was recovered from wastes contg. $\text{Ge}(\text{OH})_4$ by double distn. of GeCl_4 with HCl , hydrolysis, and reduction with H at red heat. GeBr_4 was prepd. from Ge and Br_2 dild. with N_2 at 250°, and purified by 13 fractional distns. in a special app. in which the liquid was entirely confined in a high vacuum throughout. The first and last fractions were isolated in each distn. after the 4th, and analyzed. The last 10 at. wt. detns. were all between 72.599 and 72.609. No Si nor As could be found even in the first fractions. The analysis was made by breaking the sealed glass bulbs contg. the fractions under excess NaOH , acidifying with HNO_3 , and pptg. with AgNO_3 . The final value, 72.60, agrees with the previous work on GeCl_4 ; it is 0.1 higher than the accepted value. ALFRED W. FRANCIS

The metastability of matter and our physical "constants." ERNST COHEN. *Z. Elektrochem.* **31**, 539-42 (1925); cf. *C. A.* **18**, 1930; **19**, 1512, 1981. —In some cases errors up to 10% occur in older detns. of physical consts. because the investigated substances were mixts. JOHN T. STERN

Coördination and covalency. J. A. V. BUTLER. *Trans. Faraday Soc.* **1925**, (adv. proof).—The nature of the coordination bond is discussed. The formation of coördinated complexes cannot be due in general to the tendency of the central atom to attain the configuration of the next higher inert gas. The electrons contributed by the coördinated groups form a distinct group round the central ion. A distinction is made between (a) covalency, the mutual sharing of electrons by two atoms so as to complete already existent groups, therefore involving negative valences, and (b) coördination, the formation of new groups of electrons outside the last group represented in the ion. It is proposed to use the specific term "coordination valency" for the number of coördinated groups. It is assumed that the coordination electrons enter the main "quantum group" next to that represented in the central ion. Two factors which det. the actual coördination valences are (1) the symmetry of the force field of the central ion, and (2) a correlation between the coordination valency and the electrovalency of the ion. The constitution of the oxy acids is discussed from the same point of view.

The density at zero absolute and the total expansion for organic compounds. W. HERZ. *Z. anorg. allgem. Chem.* **149**, 230-4 (1925); cf. *C. A.* **13**, 2787; **15**, 3574; **16**, 1191, 1343.—H. has recalcd. the d. at zero abs. of 54 common org. compds., using van Laar's equations $d_0/d_k = 2/(1 + \gamma)$ and $2\gamma = 1 + 0.038 \sqrt{T_k}$, where d_0 = the d. at zero abs., d_k = the crit. d., and T_k = the crit. temp. There is also included in the table the total expansion of the compds., defined as the difference between the mol. vol. at the crit. pt. and the mol. vol. at zero abs. R. L. DODGE

The thermal expansion of a few alkali halides at low temperatures. II. F. A.

HENGLEIN AND G. HÄHNEL. *Z. physik. Chem.* **117**, 285-92(1925); cf. *C. A.* **19**, 1369.—Detns. of the sp. gr. at 0° , -79° and -184° are extended to Li and Rb and to the fluorides of Li, Na and K. The values differ slightly from those of Baxter, because the salts were crystd. from fusion and sometimes slightly decompd. The expansion coeffs. are calcd. and given in systematic tables.

JOHN T. STERN

A calculation of some characteristic constants of free ammonium. A. BALANDIN. *Z. physik. Chem.* **118**, 114-8(1925); cf. *C. A.* **18**, 3141; **19**, 2581.—On the basis of formulas previously derived, B. calcs. for the heat of formation of free NH_4 from its elements, $-17,800$ cal.; for its mol. vol., 47.9 cc.; for its d. in the solid state, 0.356 .

R. J. HAVIGHURST

Some critical constants of furfural. W. V. EVANS AND M. B. AYLESWORTH. *Ind. Eng. Chem.* **18**, 24-7(1925).—The b. p. and n_D value of highly purified furfural were found to be 161.7° (760 mm.) and 1.52608 , resp. The crit. soln. temp. curve for the system furfural- H_2O was detd., the crit. soln. temp. being 120.9° and the crit. soln. concn. 50.7% furfural. The vapor pressure curve was also detd. (for the first time) from 40° to 170.6° , viz., over the pressure range $8-966$ mm. Some of the data agree, other data disagree with earlier work by other investigators.

C. C. DAVIS

The properties of active hydrogen. K. F. BONHOEFFER. *Z. Elektrochem.* **31**, 521-2(1925).—A review of work previously given in detail (cf. *C. A.* **19**, 915, 2915).

E. R. SCHIERZ

Linear compressibility of fourteen natural crystals. P. W. BRIDGMAN. *Am. J. Sci.* **10**, 183-98(1925).—Linear compressibility was measured at 30° and 75° in the pressure range $0-12,000$ kg. cm^2 for the following natural crystals: Cubic-fluorite, magnetite, cobaltite, galena, pyrite, argentite, sphalerite; trigonal-tourmaline, quartz, calcite; tetragonal-rutile; orthorhombic-celestite; monoclinic-spodumene, crocoite. For the non-cubic crystals, linear compressibility was measured in several directions, so that cubic compressibility could be calcd. For all the crystals except quartz, the relation between pressure and change of length may be represented by a second-degree equation, the rate of change being less at higher temps. There is no observable connection between linear compressibility and crystallographic axial ratios. Above 30° and 9000 kg. cm^2 , argentite and sphalerite undergo a change, probably a polymorphic transition.

R. J. HAVIGHURST

Very thin transparent metal foils. CARL MÜLLER. *Sitzb. preuss. Akad. Wiss.* **1925**, 464-70.—Films of Ni, Au, Pt, Ag and Fe of a thickness of 0.01μ were prepd. by electrodeposition on thin metallic supports. In order to protect the film from the action of acids (used to dissolve the support) it has deposited on it a 0.01 -mm. layer of the supporting metal. Before etching then, the desired film is sandwiched between two films of readily sol. supporting metal. The etching acid does not come in contact with the film until the very end of the operation. In this way it has been possible to obtain films of Au and Ni 6 cm. in cross-section and 0.04μ thick. Films of smaller cross-section had a thickness of 0.01μ . The thickness was calcd. from the wt. and the generally accepted values of sp. gr. Under the microscope the films appeared glass-like and without structure and with but few scattered holes. The Ni films were very elastic and those of 0.04μ thickness carried a current of 0.3 amp. sq. cm. in air without being oxidized. Spectrographic measurements are given.

E. R. SCHIERZ

Crystal structure and chemical constitution. K. WEISSENBERG. *Z. Elektrochem.* **31**, 530-6(1925).—Schoenflies has shown that the whole knowledge of crystals is governed by a single hypothesis—that in every crystal the material particles build a homogeneous domain with sharp periodic discontinuities in 3 directions. W. develops this both from the geometrical (static) and the dynamical structure viewpoints, using the terms island and dynad, resp., to designate unit quanta of particles structurally equiv. and separable. Islands (or dynads) are classified in 4 types—micro, chain, net, space lattice. Only those of the micro class contain a finite no. of atoms and a finite vol. The other 3 groups contain an indefinite no. of micro units arranged according to the group name. If J_0 = vol. of a micro-island (or dynad), n = the no. of chem. mols. of the crystal substance exptly. observed in the elementary unit, and $n_R, q_{\min.}$ = the smallest no. of structurally equiv. points in the elementary unit permissible in the space group of the crystal, then $J_0 \leq n/n_R, q_{\min.}$; that is, the crystal contains in the elementary unit at least as many structurally equiv. micro-islands (or dynads) as the smallest no. of structurally equiv. point positions indicated in the elementary unit. Three tables (including elements, inorg. and org. compds.) constructed from data in Ewald's "*Kristalle und Röntgenstrahlen*" show the identity of n and $n_R, q_{\min.}$ in nearly every case.

R. H. ABORN

Determination of the structure of some simple inorganic substances. H. MARK,

W. BASCHE AND E. POHLAND. *Z. Elektrochem.* **31**, 523 (1925).—By use of the app. of Keesom and de Smedt or Simon and Simson modified to suit the properties of the substances being investigated M., B. and P. have detd. that the unit cube of CO_2 in which $a = 5.62$ A. U. contains 4 mols. The unit cell of NH_3 also contains 4 mols. The structures of B_2H_6 and C_2H_6 are very similar and differ only in the size of the unit. BaSO_4 , SrSO_4 , PbSO_4 , KMnO_4 and KClO_4 crystallize in the space group I^{h}_{16} , while CaSO_4 belongs to group I^{h}_{17} . It has not been possible to det. the structure definitely, but it is probable that the SO_4 groups are not uniformly distributed around the heavy metal but that one has a special position. E. R. SCHIERZ.

The crystal structure of primary potassium phosphate and isomorphous salts. O. HASSEL. *Z. Elektrochem.* **31**, 523 (1925). KH_2PO_4 , the corresponding NH_4 salt, and the corresponding K and NH_4 arsenates all crystallize isomorphous in tetragonal scalenohedral class. In this report only the K and NH_4 phosphates were subjected to X-ray analysis. Single crystals prepd. from slowly cooled aq. solns. were used in the rotation-diagram method employing both Cu and Ni K radiation. From measurements of specimens on the diagrams, the base edge a of the KH_2PO_4 unit was found to be 7.42 A. U., the height $c = 6.97$ A. U., and $c/a = 0.939$. For the NH_4 salt $a = 7.48$ A. U., $c = 7.56$ A. U., and $c/a = 1.01$. The unit is body-centered tetragonal contg. 4 mols. Intensity comparisons indicate the positions of the mol. components which are shown in an accompanying sketch. R. H. ABORN.

X-ray reflections from mercuric iodide. R. J. HAUGHURST. *Proc. J. Sci.* **10**, 556–8 (1925).—Powder-method photographs and ionization spectromet. measurements on single crystals were used in the study of tetragonal HgI_2 . The unit cell contains 2 mols of HgI_2 with $c = 12.349$, $a = 4.356$ A. U., and $c/a = 2.835$. The data were not sufficient to det. the a positions. R. J. HAUGHURST.

Confirmation of the presence of a non-tetrahedral carbon atom in crystals of pentaerythritol. M. L. HUGGINS AND S. B. HENDRICKS. *J. Am. Chem. Soc.* **48**, 1647 (1926).—Additional data confirming the crystal structure of pentaerythritol, $\text{C}(\text{CH}_2\text{OH})_4$, as previously reported by Mark and Weissenberg, *Chem. Abstr.* **18**, 347, have been obtained. These data verify the non-tetrahedral arrangement of atoms at the central C atom of the mol. GEORGE L. CLARK.

The crystalline structure of perovskite. G. R. LEVI AND G. NATTA. *Atti accad. Lincei* [6] **2**, 39–46 (1925).—Perovskite is cubic in angle but its phys. properties indicate it to be rhombic. X-ray study by the Debye-Scherrer method shows it to be cubic. The elementary cell is a cube 7.68 A. U. wide, contg. 8 mols. of CaTiO_3 . The Laue diagrams showed, however, that at ordinary temps. its pseudocubes are broken up into 2 rhombic forms. Other instances of such crystallographic pseudo-symmetry are cited. E. J. WITZEMANN.

An X-ray examination of some ammonia catalysts. R. W. G. WYCKOFF AND E. D. CRITTENDEN. *J. Am. Chem. Soc.* **47**, 2866 (1925).—X-ray photographs, prepd. in the usual way for powder photographs, were obtained (1) from various fused Fe oxides having compns. near to Fe_3O_4 and other richer in iron (Fe than Fe_3O_4), (2) from artificial magnetites contg. various amt. Al_2O_3 and K_2AlO_4 as promoters, and (3) from the Fe catalysts obtained by reducing the iron oxides. One function of the promoters of Al_2O_3 and K_2AlO_4 in reduced Fe oxide catalyst for the catalysis of NH_3 is suggested. The length of the edge of the unit cube a_0 of magnetite was found to be $a_0 = 8.37 \pm 0.010$ A. U. In magnetites contg. mixtures of FeO the substance occurs as a sep. phase. This phase disappears when the equiv. amt. of the promoter, Al_2O_3 , is added. The compn. of the oxide thus adjusted toward Fe_3O_4 with the formation of FeAl_2O_4 , which is apparently in solid soln. in the magnetite. The value of a_0 for magnetite contg. K_2AlO_4 differs so little from 1. for pure Fe_3O_4 that it is impossible to decide whether or not there is solid soln. of one in the other. a_0 for the α -iron obtained by the reduction of Fe_3O_4 is 2.879 ± 0.004 A. U. The size of the unit cell of Fe in the reduced material contg. the promoters differs from that of pure Fe by less than 0.1%. The presence of the composite promoter, K and Al oxides, in the reduced catalysts has been found to maintain a large surface of Fe by preventing the rapid growth of the Fe crystals. R. L. DODGE.

X-ray examination of inner structure of strained metals. IV
ained in extension.

kind of model is characterized by a certain lattice axis placed along a fixed direction, about which the rotation of the lattice takes place freely. Thus the rearrangement of the axis is linear. This kind of model may be used to represent a fiber structure regularly formed, though a slight deviation of the axis from the fiber direction may occur in the actual case. In the second kind the rearrangement of the axis of rotation is planar, being allowed to occupy any direction in an assigned region of a plane, and the lattice rotates about this axis within a certain range. In the mid position of the lattice, another axis which is perpendicular to the axis of rotation stands along the fiber direction. This kind of model may be taken for representing the fiber structure in which a particular axis of the lattice deviates from the mean fiber direction to a greater extent than the structure represented by the first kind. The X-ray examn. of α -iron plastically strained in extension, compression and torsion was worked out by taking the diffraction figures of the specimens taken from the strained metal in various directions. The patterns of extension and compression specimens were analyzed and explained by reference to the two kinds of model structures. The pattern of torsion specimens was also explained by referring to one of the models. The particulars of the model structures are as follows (coordinates refer to lattice axis more or less regularly rearranged in the axial direction of test piece): Extension, (110); rearrangement deviating, symmetry of second kind, 001 in lateral direction; compression, (111) fairly regular, first kind, compression, (100), deviating, second kind, 011 in lateral direction; torsion, (110) and (121), deviating, second kind, (111) in tangential direction. V. **The mechanism of crystal rearrangement, and the cause of strain-hardening.** *Ibid* 287-305. The crystal rearrangement as was observed in the X-ray examn. of metals, crystd. in the cubic lattice both of the face-centered and cube centered type, and strained plastically in extension, compression and torsion, is reviewed by reference to the 2 kinds of models of the crystal structure. The mechanism of the crystal rearrangement was investigated by taking the slip and rotation as the cause of distortion, and by assuming the slip direction for each kind of lattice. The structure as was to be expected from the theoretical consideration in the respective cases of the straining action, was found to conform to the exptl. results. Next the cause of the strain hardening, which cannot be explained geometrically as the direct consequence of the rearrangement, was explained by considering the nature of the slip resistance. As the result of the calcn., the slip resistance was found to depend on the crystal size, n/z , the finer the crystal, the higher the slip resistance. This agrees with the well-known fact that fine grained material is usually hard and strong. G. L. C.

The glowing of the oxides of certain metals. J. BOHM. *Z. anorg. allgem. Chem.* 149, 217-22 (1925). When pptd. Se_2O_3 , Fe_2O_3 , Cr_2O_3 , TiO_2 , ZrO_2 , Ce_2O_3 and Ta_2O_5 are heated to dull redness, the material begins to glow brightly for a short time. The temp. at which this change takes place and its extent depend on the method of prepn. of the oxide. Various explanations of this phenomenon have been advanced: allotropic transformation, increase in size of particles, and transition from amorphous to cryst. state. By Debye Scherrer X-ray spectrograms made on samples of the oxides before and after glowing B. has shown that the third explanation, the transition from the amorphous to the cryst. state, is the correct one. The explosive devitrification of certain glasses such as CuB_2O_6 , $\text{Co}_2\text{B}_2\text{O}_7$ and MnB_2O_7 on heating to 700-800° is also caused by a similar transition. The disruption of Gore's explosive Sb is another analogous phenomenon. R. L. DODGE.

Aluminium hydroxide and iron hydroxide. I. J. BOHM. *Z. anorg. allgem. Chem.* 149, 203-16 (1925). Several natural and artificial hydroxides of Al and Fe were studied by means of the Debye Scherrer X-ray spectrograms. The empirical formulas of the pure hydroxides were detd. by chem. analysis. Three cryst. hydroxides of Al occur in nature: diaspore, bauxite and hydrargillite. The various artificially prepd. hydroxides were identified by comparing their X-ray spectrograms with those of the 3 natural hydroxides. The formulas of diaspore and hydrargillite are AlOOH and $\text{Al}(\text{OH})_3$, resp. The formula of the artificial bauxite was found by analysis to be AlOOH . Al hydroxide gel, made by pptn. from cold solns., was amorphous. That prepd. by pptn. from boiling solns. gave the characteristic bauxite spectrogram. The hydroxide pptd. from alkali aluminates showed the characteristic hydrargillite spectrogram. Dialyzed Al sols. showed the bauxite spectrum, although the chemical formula was $\text{Al}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$. The exceptional width of the spectrum lines indicates that they are due to very small crystals of bauxite distributed through the sol. Two cryst. Fe hydroxides occur in nature, goethite and brown iron oxide, both having the formula FeOOH . Limonite, brown hematite, lepidokrokit, and xanthosiderite, all minerals commonly regarded as chem. individuals, are in reality finely cryst. goethite. Arti-

ficial. The hydroxide gels pptd. either cold or hot are amorphous. Aging of the gels results in no synthetic, cryst. hydroxide, but invariably causes dehydration to Fe_2O_3 . Artificial goethite was prepd. by digesting the gel with 2N KOH in an autoclave at 150° . R. L. D.

Collagen. R. O. HERZOG AND H. W. GONNELL. *Ber.* 58B, 2228-30(1925).—X-ray examn. was made of collagen from 6 widely varying sources, including 3 from connective tissue and 3 from cartilage. The diagrams for all except fish scales were cloudy, showing the presence of amorphous material with the cryst. In some cases digestion with trypsin soln. removed the amorphous material leaving the cryst. The cryst. component of all the collagens gave exactly the same diagram. The elastin from the neck ligament of cattle thus appears identical with collagen. The interference bands are not numerous enough to establish the cryst. system. It is clear, however, that the mol. wt. cannot be greater than about 685. Thus a mol. occupying an elementary cell of a collagen cryst. cannot contain all 13 of the amino acids found in gelatin. Most of the amino acids therefore appear to be present as the amorphous impurities. The heavy aggregates that have heretofore been called the "molecules" of such proteins as collagen are really colloidal aggregates of true mols. of comparatively low mol. wt. F. L. BROWNE

Gelatin and collagen. J. R. KATZ AND O. GERNGROSS. *Naturwissenschaften* 13, 900-3(1925).—In the X-ray diffraction spectrum obtained from dry gelatin films, prepd. with and without mechanical stress, the diffuse ring and the wide, sharp ring occurring in the unstressed material (periods of identity 4 and 2.7 A. U., resp.) changed their appearance in stressed gelatin (100% elongation). The sharp ring dissolved into two crescent-shaped parts in the direction of the stress, two broad interference spots appeared (10 A. U.) on both lateral sides of the central blackening, two diffuse elliptical spots at $5\frac{1}{2}$ A. U., no peripheral spots. This spectral diagram is in every detail analogous to that of fibrous collagen. From a theoretical standpoint this is of great importance, in that for the first time a fiber X-ray diagram has been artificially produced. Theoretical discussion is as yet withheld. B. J. C. VAN DER HOEVEN

The flow of a real gas from one vessel into another under constant volume conditions. MICHAEL ZACK. *Z. komp. u. flüssige Gase* 24, 111(1925).—Equations for consideration of the problem of gas flow between vessels are derived from van der Waals' equation of state in place of the commonly used perfect gas law. R. L. D.

The periodic crystallization of pure substances. E. S. HEDGES AND J. E. MYERS. *J. Chem. Soc.* 127, 2432-4(1925).—When 5 g. of $\text{C}_6\text{H}_5\text{COOH}$ is warmed with 12-20 cc. of an equal vol. mixt. of H_2SO_4 and EtOH and allowed to cool, crystn. in periodic, concentric spheres starts from nuclei and spreads radially throughout the vol. of the soln. The rings are as much as 1 cm. apart at first, the distance becoming progressively shorter as they spread out. The layers consist of closely packed crystals of $\text{C}_6\text{H}_5\text{COOH}$ sep'd. by spaces contg. mostly soln. with enough crystals to give rigidity to the whole mass. F. L. BROWNE

Liquid mixed crystals. ROBERT WALTER. *Ber.* 58B, 2303-10(1925).—The fact that the phenomena of cryst. liquids are exhibited by certain binary mixts. of liquids neither of the components of which in the pure state shows such properties (*C. A.* 1, 2114) does not prove that the cryst. liquid state is a matter of emulsion formation as maintained by Tammann (*Aggregatzustände*, Leipzig 1922, p. 286). The observations can be easily reconciled with the cryst. structure viewpoint if the cryst. liquid phases of the pure liquids are "latent" and not realizable because the solid phase crystallizes so easily that the liquid cannot be undercooled. Since the curve of compn. vs. m. p. II (the temp. of equil. between amorphous liquid and a solid phase) has a rough V shape, while the curve of compn. vs. m. p. I (the av. temp. of the m. p. region for the cryst. liquid-amorphous liquid) may be a straight line, it is possible for the latter curve to intersect the former, thus leaving a region of compn. of the liquid mixt. in which the cryst. liquid is no longer latent. It is shown for 12 liquid pairs that the compn.-m. p. I curve is a straight line for chem. similar liquids and that the latent m. p. I of a liquid can be obtained by extrapolation of the curve for its mixts. with a second liquid of known m. p. I. The latent m. p. I for 2 liquids having been so det'd., the compn.-m. p. I curve for their mixt. can be plotted. By this method, it is shown that the above conditions obtain for the liquid pairs studied by V. and G. and the m. p. I for each liquid is det'd. In the same way it is found that 17 liquids which have not been known previously to form cryst. liquids but whose chem. compn. indicated that they might, actually do so. F. L. BROWNE

The cause of change in physical properties when liquids are strongly dried and the influence of temperature on the rate of drying. S. B. MALI. *Z. anorg. allgem. Chem.*

149, 150-6(1925).— CCl_4 , C_6H_6 , CS_2 and $\text{C}_6\text{H}_5\text{CH}_3$ were separately dried in closed, evacuated tubes for 5 months. Samples of each liquid were dried at 2 temp. ranges 27-30° and 43-45°. Direct contact between P_2O_5 , the drying agent and the liquid was prevented, the drying taking place through the vapor phase. The vapor pressures of the dried liquids were measured, in the drying app., at temps. between 21° and 63° by a static method. In each case the vapor pressure was decreased by the drying. The decrease is due in part to a displacement of the internal equil. in the liquid. The samples dried at the higher temp. showed the greater decrease of vapor pressure. This fact is attributed to a greater drying rate at the higher temp. Preliminary measurements indicated that the surface tension of dried C_6H_6 differed appreciably from that of ordinary C_6H_6 . R. L. DODGE

Vapor pressures and miscibility of binary mixtures of liquids. K. F. HERZFELD AND W. HEITLER. *Z. Elektrochem.* 31, 536-9(1925).—Simplified theoretical derivation based upon the work of van der Waals and Dolezalek and comparison of the resulting data with exptl. values. JOHN T. STERN

Plasticity. E. C. BINGHAM. *J. Phys. Chem.* 29, 1201-4(1925).—Introduction, Defining plasticity and related properties. Cf. *C. A.* 19, 2767. E. C. B.

Plasticity of single crystals. W. P. DAVEY. *J. Phys. Chem.* 29, 1211-5(1925).—The plasticity of single crystals is not complicated by considerations of grain size but has to do with the slipping of planes of atoms upon adjacent planes. The plastic ductile and malleable metals Cu, Ag, Au, Al, etc., have face-centered cubic structures and the relatively non-plastic metals as Cr and W, have body-centered cubic structures. Based upon the at. populations in the various planes of the crystals, a variety of predictions are found to be verified. Thus a single crystal of zinc stretched beyond its elastic limit should show block-slip along the 100 planes to a very much greater extent than along the 001 planes. Impure Co should be more ductile than the pure metal. The simple cubic structure of NaCl is weak, giving no plasticity. E. C. B.

The plasticity of clay. W. D. BANCROFT AND L. E. JENKS. *J. Phys. Chem.* 29, 1215-7(1925).—Clay workers include in their definition of plasticity the property of burning to a coherent mass. If the bonding material is hydrous alumina, hydrous silica or some intermediate compn., it must maintain its gelatinizing tendency after drying in the sun, perhaps with the aid of an electrolyte or org. matter. Expts. were made with electrolytes. Non-plastic kaolin was made very plastic by 0.25% LiCl. There is no relation between the plasticity of clays and their Li content. Probably the humus plays an important part. E. C. B.

The Ostwald viscometer as a consistometer. W. H. HERSCHEL AND R. BULKLEY. *J. Phys. Chem.* 29, 1217-24(1925).—The Ostwald viscometer is the standard instrument for detg. the viscosity of rubber solns. Since these solns. are plastic, measurements should be made under several shearing stresses; hence external pressure should be applied. The equations to be used are given. E. C. B.

Plasticity in relation to gelatin. S. E. SHEPPARD. *J. Phys. Chem.* 29, 1224-32(1925).—Exptl. data are given on the plasticity and elasticity of gelatin and the conclusion is reached that the transition temp. from gel to sol. is dependent on the concn. and the method of prepn. E. C. B.

Plasticity and structure in gelatin systems. R. H. BOGUE. *J. Phys. Chem.* 29, 1233-9(1925).—Largely discussion of the definiteness of transition between sol and gel. M. p., sp. rotation, and plasticity measurements all fail to show a definite temp. The transition temp. as detd. by the plastometer depends upon the concn. and perhaps upon the p_H and the sensitivity of the instrument. E. C. B.

Plasticity as applied to viscose and artificial silk. C. S. VENABLE. *J. Phys. Chem.* 29, 1239-43(1925).—Plasticity is a fundamental property of silk. The plasticity constns. are valuable from both a technical and scientific standpoint. For an accuracy greater than 1% the variable-pressure plastometer should be used. The ripening of viscose solns. is shown to be easily controllable, by the plastometer. E. C. B.

Plasticity in relation to cellulose and cellulose derivatives. S. E. SHEPPARD AND E. K. CARVER. *J. Phys. Chem.* 29, 1244-63(1925).—Criticizing considerable work on the "apparent viscosity" of gelatin on account of the failure to use more than one shearing stress or to specify the shearing stress used, S. and C. measure the plasticities of cupraammonium cellulose solns. Small amts. of O interfere with the reproducibility of results. The plasticities of a series of solns. of nitro cotton in MeOH, show that the yield values increase with the concn. along an inflected curve. The mobilities decrease rapidly with the concn. Considering the elastic behavior of cellulose esters under both steady and alternating stresses, they note that these materials behave much more

like metals than like rubber. They conclude that fibrils are present consisting of chains of mols. held together by residual valence. E. C. B.

Plasticity of starch paste. CARL BERGQUIST. *J. Phys. Chem.* **29**, 1264-5(1925).—The chemical analysis of a starch gives little idea of the character of the paste which it will give. The commercial viscometers have to be used at too low a concn. and the starches "thin down" on running and finally they do not measure the two parameters of yield value and mobility. By following a special technic, the plastometer gives values for control purposes, obtainable in no other way. A complaint on a starch being thin can be verified, without calling on a man's personal judgment, and numerical values can be assigned to the different qualities of starch paste. A 7% commercial starch which gives a mobility of over 0.055 at 25° is not a first-grade starch. The yield values vary between 250 and 400 but are not so important as the mobility. The plasticity is not a measure of adhesiveness, which may possibly be measured by the surface tension. Pastes may be stirred at temps. over 70° without changing the yield value but there is a rapid loss in yield value at ordinary temps. which has important applications. The Bingham and Murray instrument gives values which are different from those obtained with the Bingham and Green instrument. It is believed that there is better adhesion between the paste and the glass tube in the former. E. C. B.

Some observations on the Plasticity Symposium. F. G. BREYER. *J. Phys. Chem.* **29**, 1266(1925).—Granting that plasticity is dependent on two parameters, it is confusing to say that that one substance is more plastic than another. We should agree on comparing yield values. Since adhesion, giving rise to flocculation, is most important in affecting the yield values, the use of the microscope is highly desirable in connection with plastic flow, because flocculation can be readily observed.

E. C. B.

Plasticity of dental impression compound. W. S. CROWELL AND ALBERT SAUNDERS, JR. *J. Phys. Chem.* **29**, 1267-82(1925).—Impression compd. contains stearic acid, resins, oils and talc or other filler. It must be soft enough at 55° to take the exact pattern given by the muscles of the mouth and yet be rigid at 37.5°. The crystn. of the stearic acid is used to effect the rapid changes in plasticity but the mixt. is so complex that accurate control is necessary. The measurement of the fluidity of the wax above 46° gave no difficulty, but concordant results were not obtained below this temp. Capillaries with radius of 0.15 cm. gave better results than those with much smaller bore. The yield value was apparently higher with the larger tubes, which was proved to be due to the higher shearing stress. On adding talc to wax the fluidity is lowered and zero fluidity is reached at a concn. of 19.9 vol. %. This concn. is independent of the temp. As talc is added in excess of 19.9% a finite yield value is developed. The yield value is independent of the temp. The mobility-temp. curve resembles the fluidity-temp. curve. E. C. B.

A simple plastometer for control use with dental creams. E. MONESS AND P. M. GIESY. *J. Phys. Chem.* **29**, 1282-8(1925).—The plastometer is constructed entirely of standard pipe fittings and is of the Bingham and Murray type. Channeling of the material was encountered and overcome. The resistance to flow outside of the capillary was noticed. While the Bingham and Murray method is not mathematically rigorous, it is sufficiently accurate mathematically to be within exptl. error. E. C. B.

Source of error in the mechanical analysis of sediments by continuous weighing. J. R. H. COUTTS AND E. M. CROWTHER. *Trans. Faraday Soc.* **1925** (advance proof).—The detn. of the size distribution curves of suspensions is sometimes carried out by weighing the sediment accumulating on a balance pan hung near the base of the column of suspension. This method is not beyond criticism, for the low d. of suspensions, immediately below the pan after the sedimentation has proceeded for a few minutes, inevitably sets up a flow of liquid which interferes with the free vertical fall of the particles. With the large narrow-rimmed pans hitherto used the observed yields are appreciably below the theoretical values. With the pan close to the base there is a very rapid change of yield with very small changes in the position of the pan. The extent of the disturbance varies with the size of particle and thus produces a distortion of the distribution curves. JAMES M. BELL.

Adsorption. Adsorption by coconut charcoal from alcohol-benzene and acetone-benzene mixtures. F. G. TRYHORN AND W. F. WYATT. *Trans. Faraday Soc.* **1925** (advance proof).—The charcoal was weighed into test-tubes closed by tight rubber stoppers. Over the charcoal was placed a smaller, open test-tube contg. a suitable mixt. of liquids. After 5 days at 20° the total wt. of vapors adsorbed was detd. from the increase in wt. of the charcoal. From this and the compn. of the liquids in the small tube before and after the expt. the amt. of each substance adsorbed from the vapor

by the charcoal can be computed. Adsorption isotherms for each component of mixts. of alc. and C_6H_6 and of acetone and C_6H_6 were detd. over the complete range of compns. By an analogous method measurements were made of the compn. of the vapors in equil. with mixts. of the above liquids at 20° . A comparison of the results of adsorption by charcoal from the liquid and the vapor phases supports the conclusion that an adsorbed film in equil. with a satd. vapor must be also in equil. with the liquid in contact with that vapor. Alc. is selectively adsorbed from all mixts. of alc. and C_6H_6 . From acetone- C_6H_6 mixts. acetone is selectively adsorbed from mixts. contg. up to 72 mol. % of acetone in the vapor phase. Above that value C_6H_6 is selectively adsorbed to a slight extent.

F. L. BROWNE

Transformation of water of hydration into water of adsorption by mechanical reduction of the size of crystal hydrates. TOKUTARO HAGIWARA. *Japn. J. Chem.*, **2**, 27-32(1923).—The mechanical grinding of crystals of $Al_2O_3 \cdot 3H_2O$ weakens the union of the H_2O so that it has largely the properties of H_2O of adsorption. This confirms von Veimarn (*Kolloid Z.* **4**, 198(1909), cf. *C. A.* **3**, 393). Similar results have been found with $Fe_2O_3 \cdot H_2O$.

C. J. WEST

Adhesive forces in solutions. V. The adsorption of complex compounds. NIKOLAI SHILOV and BORIS NEKRASSOV. *Z. physik. Chem.* **118**, 79-88(1925); cf. *C. A.* **16**, 2055.—The process of adsorption may be analogous to that of complex-ion formation. Forces of electrostatic nature, which govern chem. combination, may also govern adsorption. The adhesive forces may be of approx. the same magnitude as the chem. forces in complex compounds. An investigation has been made of the stability in the presence of adhesive forces of the following complex compds.: (1) double salts—schonites, $MSO_4(NH_4)_2SO_4 \cdot 6H_2O$, where M represents the bivalent Ni, Zn, Mg, Mn, Cd, Co, Fe, Cu ions, (2) metallic amino salts— $[Cu(NH_3)_4]SO_4 \cdot H_2O$, $[Cu(NH_3)_4]Cl_2 \cdot H_2O$; (3) compds. with complex ions— $[Co(NH_3)_6]Cl_3$, $[Co(NH_3)_5NO_2]Cl_2$, 1,6- and 1,2- $[Co(NH_3)_4(NO_2)_2]Cl$, $[Co(NH_3)_3(NO_2)_3]$, $Na[Co(NH_3)_2(NO_2)_4]$, $Na_3[Co(NO_2)_6]$. Activated charcoal was the adsorbent. In every case, the complex mol. was split up, and the different parts were adsorbed in different amts. The same amt. of $(NH_4)_2SO_4$ was adsorbed from each of the schonite series, but the adsorbability of the metal ions varied, in qualitative correspondence (with the exception of Mn and Cd) with the lowering of the soly. of the metal sulfate by the formation of its double ammonium salt. Probably the complex ion $[Cu(NH_3)_2]^{++}$ was adsorbed from the cupric amino compds. The complex cobaltic ions were split up by adsorption and reduced to cobaltous ions with the adsorption of $[Co(NH_3)_2]^{++}$. The excess ammonia remained in soln. as ammonium salt. From the compds. with Co in the anion, Co was more strongly adsorbed than Na. The unsymmetrical *cis*-compd. 1,2- $[Co(NH_3)_4(NO_2)_2]Cl$ was more strongly adsorbed than the isomeric *trans*-compd. The non-ionized neutral $[Co(NH_3)_3(NO_2)_3]$ was more strongly adsorbed than the analogous ionized compds. R. J. H.

Adsorption forces and their electrical nature. II. The electrical moment of the adsorbed molecule and the superficial energy of the adsorbent. BORIS ILIIN. *Phil. Mag.* **50**, 1144-6(1925); cf. *C. A.* **20**, 135.—In a former paper (*C. A.* **18**, 3508) I. developed a formula for the elec. moment (τ) of the adsorbed mol. which related it, according to his theory, with E_0 the field tension of adsorption: $\tau = (E_0/4\pi N_L)[(\epsilon-1)/\epsilon]$, where N_L is the Loschmidt const. and ϵ is the dielec. const. In the present paper E_0 is calcd. from Q the heat of adsorption of gases by charcoal (Titoff data) and by mica (Langmuir) according to the formula $E^2/8\pi = 1.1 \times 10^{10}$ erg. cm.⁻³ for charcoal, and $= 0.6 \times 10^{10}$ erg. cm.⁻³ for mica. By substituting these values in the formula for τ the following values were obtained:

		H_2	A	N_2	CO	CH_4	CO_2	C_2H_4
Charcoal	$\{ Q \text{ calcs.}$	2408	3990	4270	4860	5570	6560	7800
	$\{ \tau \times 10^{19}$	4.1	8.7	9.1	10.9	14.8	15.4	20.5
Mica	$\{ Q \text{ calcs.}$..	1530	2390	2990	3090
	$\{ \tau \times 10^{19}$	3.0	6.4	6.6	7.9	10.8	11.2	15.0

On the assumption that the adsorbing surface per g. of charcoal is 10^5 cm.² the surface tension σ of the solid adsorbed is calcd. to be 1000 erg./cm.²

S. C. LIND

Researches on the adsorption of dissolved substances. J. BANCELIN. *J. chim. phys.* **22**, 518-21(1925).—In adsorption expts. it is difficult to obtain duplicate surface areas, even by use of insol. cryst. material, as $BaSO_4$. The purpose of the present work is to det. the relation of adsorbed material to adsorbing surface, and to verify Gibb's formula for adsorption as a function of surface tension.

ROSALIE COBB

Layer filtration, a contribution to the theory of the gas mask. WERNER MECKLENBURG. *Z. Elektrochem.* **31**, 488-95(1925).—By observing the effectiveness of the

charcoal filter of a gas mask while varying the velocity of passage of air through it; the concn. of chloropicrin in the air; the cross-section of the filter; and the surface/vol. ratio of the granules of charcoal, M . has derived an equation for detg. the effective life of a filter: $RZ = (k/v.C_0)(V-Qh)$. RZ is the time from the beginning of filtration to the time when the poisonous "gas" can just be detected in the filtered air; v is velocity of air in l. per unit time passing through the cross-section of the filter; C_0 is the amt. of gas per l. of entering air; V is the total vol. of the filter; Q is the cross-section of the filter; h is calcd. from the Nernst theory of velocity in heterogeneous reaction from the equation $h = (\delta/D.F). (\pi/\kappa Q) [\ln (C_0 - C')/(C_x - C') - (C_0/C_0C')]$, in which δ is the thickness of the layer of gas adhering to the surface of the charcoal; D is the diffusion const. of the gas in air; F is the surface of the charcoal per cc.; κQ is that portion of the cross-section of the filter not actually occupied by charcoal; C_x is that concn. of gas in air below which it is not possible to detect the gas; C' is the vapor pressure of the liquified gas in the capillaries of the charcoal expressed in parts of gas per l. of air.

E. R. SCHIERZ

The nature of the interfacial layer between an aqueous and a non-aqueous phase.

FRANCIS Usher. *Trans. Faraday Soc.* 1925 (advance proof).—A comprehensive theory of the layer which forms the boundary between an aq. liquid and an "insoluble" substance in contact with it should give an adequate explanation of 3 distinct classes of phenomena: (1) relative movement of the two phases in an elec. field and the converse production of a diff. of potential by their relative movement; (2) electrode potential and electrocapillarity; (3) stability, discharge, and flocculation of suspensions. U. gives a review of the theories relating to the region in question. As a test of these theories, expts. were made dealing with (1) the detn. of the total charge on the particles of a lyophobic suspension by neutralizing it with a measured quantity of oppositely charged ions; (2) the effect of electrolytes in modifying the surface charge. The charge per particle of radius 1.3×10^{-6} cm in a gamboge suspension which was pptd. by ferric alum, was found to be 1.45×10^{-3} e. s. u. The mobility of the particles was 1.44×10^{-4} cm./sec. at 23°. The charge calcd. from the mobility on the assumption of a Helmholtz double layer of mol dimensions is 1.7×10^{-5} e. s. u., while the assumption of a diffuse outer component of the double layer requires an even smaller charge. Flocculation expts make it clear that when the soly. product of the compd. formed from the flocculating and stabilizing ions is small, the flocculating power is detd. by it. The expts. support a theory which is adapted from those of McBain and Pauli. The surface layer of a non-aq. phase which becomes charged in contact with water or an aq. liquid consists partly or entirely of mols. of an electrolytically dissociable substance, so oriented that all the groups of one sign are directed normally from the surface toward the liquid. A small fraction of these mols. is dissociated reversibly, one kind of ion diffusing through the liquid in the neighborhood of the interface. This surface disson. theory is in harmony with facts observed in connection with the relative flocculating power of different ions, the effect of diln. of a suspension on the flocculating value of an electrolyte, the relation between mobility and size of suspended particles, and membrane equil.

R. J. HAVIGHURST

Dialysis and ultrafiltration, electrodialysis and electroultrafiltration—a comparison.

ERICH HEYMANN. *Z. physik. Chem.* 118, 65-78(1925).—The time necessary to rid a colloidal soln. of its crystalloid content by dialysis is calcd. for an ideal app. If electrodes are placed just outside the diaphragms in a dialyzing app., electrolysis and electroendosmosis also aid in drawing crystalloids from the colloidal soln. Calcn. shows that in the latter case, electrolysis is about 100 times as efficient as either dialysis or electroendosmosis in removing electrolytes from the colloidal soln. Similarly, electrolysis, if employed in an app. for ultrafiltration, will be about 10 times as efficient in the removal of electrolytes as ultrafiltration alone. *For the removal of non-electrolytes from colloidal soln., ultrafiltration is 5 to 50 times as efficient as dialysis. For the removal of a mixt. of non-ionized and ionized crystalloids from a colloidal soln., the method of electroultrafiltration is best. Exptl. observations agree qual. with the results of these calcns.

R. J. HAVIGHURST

Colloidal electrolytes. A. LOTTERMOSSER. *Collegium* 1925, 573-82.—A lecture reviewing the work of McBain and others.

I. D. CLARKE

Quantitative studies on dispersoid syntheses using P. P. von Veimarn's mechanical method. SENJI UTZINO. *Japn. J. Chem.* 2, 21-6(1923) (in German).—Data are given for the prepn. of colloidal solns. of S, Se, Te, $\text{Al}(\text{OH})_3$, BaSO_4 , Sb_2S_3 , Ag, Hg, Au and denatured protein, including the dispersion medium, the time of grinding, the av. size of the dispersed particles, concn. of the dispersed phase in the dispersion medium, color of the dispersoid soln., opalescence and max. stability. C. J. WESS

The hydrates of antimony trioxide. ARTHUR SIMON AND HEINRICH POEHLMANN. *Z. anorg. allgem. Chem.* **149**, 101-24(1925).—The purpose of this paper is definitely to establish the no. of existing antimonious acids. Solns. of tartar emetic were pptd. with HCl at 0°, 40° and 100°. The hydroxides formed contained tartaric acid and HCl adsorbed despite a thorough washing. The continuous course of the drying curves, the continuous adsorption of KOH and the vapor-pressure curves of the ppts. show that different amts. of water are being adsorbed at different temps. by the gels, because of the various sizes of the grain; but no discontinuity was observed in the curves which would indicate the formation of a definite hydrate. Freshly pptd. hydrates of Sb_2O_3 dissolve on addn. of 87% H_3PO_4 and ppt. on further addn. of the acid. The ppt. loses this property when allowed to stand for 2 hrs. or longer, but is sol. in boiling sirupy H_3PO_4 and ppts. again upon addn. of water. In contrast to the hydrates of Sb_2O_3 those of Sb_2O_5 are not coagulated by an excess of H_3PO_4 and no ppt. is formed when water is added. This behavior may be made use of for the analytical sepn. of the 2 oxides of Sb. Expts. on the displacement of water by EtOH show that the gels possess a const. vol. They have a negative charge as may be shown by electrocataphoresis. It is possible to displace the water in the hydrate completely by acetone. This, too, shows that the water in the ppt. is not chemically bound. E. K.

Hydrates and hydrogels. VII. Isomeric hydrogels of alumina. RICHARD WILLSTÄTTER, HEINRICH KRAUT AND OTTO ERBACHER. *Ber.* **58B**, 2448-58(1925); cf. C. A. **19**, 201.—When Al_2O_3 is pptd. from $\text{Al}_2(\text{SO}_4)_3$ in a slight excess of NH_4OH , washed, and dried in anhyd. acetone, a compd. contg. more water than $\text{Al}(\text{OH})_3$ is obtained. With a greater excess of NH_4OH it is possible to prep. α -monoaluminium orthohydroxide having the formula $\text{Al}(\text{OH})_3$. 100 cc. of 10% NH_4OH were poured into 600 cc. of H_2O contg. 22 g. $(\text{NH}_4)_2\text{SO}_4$ and brought to 58°. To this was added rapidly and with const. stirring 150 cc. of a soln. contg. 76.7 g. $\text{NH}_4\text{Al}(\text{SO}_4)_2$ at the same temp. The ppt. was centrifuged, washed in NH_4OH water 5 times, and dried in acetone as previously described. The freshly prepd. α -hydroxide is a white, flaky, somewhat plastic gel contg. 51.7 to 54.4% H_2O based on the Al_2O_3 (theory 52.9%). In contact with H_2O it begins to change into β -hydroxide in about $5\frac{1}{2}$ hrs., the appearance changing to a compact, yellowish, plastic gel. The β -hydroxide is believed to be a polyaluminium hydroxide, probably $\text{Al}_4\text{O}_3(\text{OH})_3 \cdot 2\text{H}_2\text{O}$. On heating with NH_3 the α -compd. loses very little H_2O but the β gives up its hydrate H_2O . The β also remains colloidal, whereas the α becomes "mineralized." The β hydroxide changes to the γ compd. on standing some months under H_2O . In the presence of NH_3 the change can be brought about in 10 days. On drying in acetone and analyzing the γ -hydroxide appears to be $\text{Al}(\text{OH})_3$, but it is so different chemically from the α that it must be considered an isomer. The α -hydroxide dissolves readily in HCl and NaOH, the β much less readily, but the γ does not dissolve in even moderately concd. HCl or NaOH. That the differences between the 3 hydroxides are due to differences in chem. compn. rather than to their colloidal nature is shown by the fact that the γ adsorbs more invertin from soln. than the β , and the β more than the α . **VIII. An alumina gel of the formula $\text{AlO} \cdot \text{OH}$.** *Ibid* 2458-62.—Al metahydroxide can be made by heating any of the 3 orthohydroxides. The α -compd. comes to the same compn. anywhere in the temp. range of 212-239°. The H_2O content is then 16.5% (17.6% theoretical for $\text{AlO} \cdot \text{OH}$). The β -compd. comes to a const. compn. in the same temp. range, but at 19.1 to 19.5% H_2O . Probably some poly-Al hydroxides are present in this case. The γ compd. comes to the H_2O content of 14.5 to 15.4% in the temp. range 242-72°, some Al_2O_3 probably being formed as well as $\text{AlO} \cdot \text{OH}$. The metahydroxide does not dissolve in moderately concd. HCl or NaOH. It is a poor adsorbent for invertase, taking up only 0.01 as much as the γ -orthohydroxide. It adsorbs *maltase* more readily than invertase, making possible the sepn. of the former from a mixt. of the 2 enzymes. **IX. Silicic acid.** RICHARD WILLSTÄTTER, HEINRICH KRAUT AND KARL LOBINGER. *Ibid* 2462-6.—The silicic acid was made either by adding SiCl_4 to 60 times its wt. of ice and H_2O or by passing a brisk stream of air through boiling SiCl_4 and thence into H_2O at 0°. The HCl formed in the reaction was largely removed by adding freshly pptd. Ag_2O . The HCl cannot be reduced below about 0.005 N without causing some Ag to go into the soln. The rest of the HCl can be removed by dialysis, but much of the SiO_2 is lost at the same time. The soln. of α -silicic acid was concd. to 5 to 7% SiO_2 by vacuum distn. at 15° in 1 hr. The soln. remained clear and fluid. When concd. to 10% SiO_2 it gelatinizes. The $3\frac{1}{2}$ to 5% solns. at 8° do not show any cloudiness with egg albumin for 2 days. More dil. solns. take still longer to form enough β -silicic acid to give a ppt. with albumin. The $3\frac{1}{2}$ % soln. remains clear for 7 days, the albumin ppt. increasing markedly as time goes on, and after 10 days the soln. gelatinizes. A 7% soln. gel-

atinizes on standing overnight, before the albumin test shows the presence of any β -silicic acid. Gels were prepd. from the solns. of α -silicic acid by pptn. with NH_4OH and NH_4Cl and drying with acetone. The H_2O content found lay between that for $\text{H}_2\text{Si}_2\text{O}_6$ and $\text{H}_4\text{Si}_2\text{O}_8$. The freshly prepd. α -silicic acid passes through dialyzing membranes very readily, but the velocity of diffusion is greatly reduced within 6 hrs. after prepn. The α -silicic acid is slightly volatile at $15\text{--}26^\circ$, small quantities passing over during vacuum distn. F. L. BROWNE

The influence of some stable colloids on the flocculation of sols and suspensions. A. BOUTARIC AND M. G. PERREAU. *Compt. rend.* **181**, 511-13(1925).—The influence of varying amts. of gum arabic, dextrin, gelatin, casein and starch on the stability toward electrolytes of the negative suspensoid sols As_2S_3 , gamboge, and mastic was detd. Starch in all proportions rendered the sols less stable. In the other cases, as the amt. of stable colloid added was increased, the sols became at first increasingly stable, then a protective action was observed, and finally at high concns. the stable sols caused coagulation without the addn. of any electrolyte. F. L. BROWNE

The influence of the time of dialysis on the aging of ferric oxide hydrosol. HANS HANDOVSKY. *Z. physik. Chem.* **117**, 432(1925).—A slightly dialyzed Fe_2O_3 hydrosol made by the method of Wintgen and Biltz (*C. A.* **18**, 1220) showed very little change in elec. cond. in 1121 days. A portion of this sol which was dialyzed for 21 days and then aged for 642 days increased in cond. markedly during the aging period. The increased cond. occurred chiefly, though not entirely, in the cond. of the dispersion medium as distinguished from that part of the cond. due to the charged particles. The aging may be due to the long time required for ions in the interior of the dispersed particles to work their way to the interface and thence into the dispersion medium. F. L. BROWNE

The coagulation of a colloidal solution by hydrogen ions. A. B. WEIR. *J. Chem. Soc.* **127**, 2245-8(1925).—The min. concn. of HCl , H_2SO_4 , AcOH , and citric acid for the coagulation of Prussian blue hydrosol was detd. and the p_{H} of the supernatant liquid examd. Coagulation took place when the p_{H} of the medium was the same, namely about 1.9, for HCl , H_2SO_4 , and citric acid. With AcOH the p_{H} was 2.3. In all cases the p_{H} of the supernatant liquid was slightly higher than that of the corresponding concn. of the acids alone, indicating that some of the acid was adsorbed by the ppt. in each case. With oxalic acid, complete pptn. does not take place until a p_{H} of 0.8-0.9 is reached. Ppts. with other acids can be reprecipitated by adding a little oxalic acid and shaking, but the ppt. with oxalic acid cannot be reprecipitated. Strong adsorption of the oxalate ion and consequent peptizing action is indicated. F. L. B.

The electroanalysis of agar. A method for the preparation of the free agar-acid. W. F. HOFFMAN AND R. A. GORTNER. *J. Biol. Chem.* **65**, 371-9(1925).—Coarsely ground, com. agar was electroanalyzed for 18 hrs. with a total elec. current of approx. 11.65 amp.-hrs. at 220 v. This procedure removes the Ca practically quant. and forms the free agar-acid. A 1% soln. of the free acid has a p_{H} of 2.475; the acid is about 56% ionized and is neutralized by NaOH below p_{H} of 4.0. The acid is apparently an acid H_2SO_4 ester, all of the S being in the form of H_2SO_4 . Sols contg. as much as 5% of the free agar-acid do not set on cooling but rigid gels are obtained on neutralization. Org. bases such as PhNH_2 and the alkaloids form salts and set to rigid gels. Possible pharmacol. uses of the agar-alkaloid salts are being investigated. The min. mol. wt. of the agar-acid is approx. 3000 and probably corresponds to the formula, $\text{R}-\text{O}-\text{SO}_2-\text{OH}$, where R is a large polysaccharide residue. This gelation of agar is the gelation of a salt and not of a complex polysaccharide. A. P. LOTHROP

The solubility of ammonium salts in ammonia. (A method for the distinguishing and separation of mono- and polybasic acids.) E. WEITZ. *Z. Elektrochem.* **31**, 546(1925).—Salts of mono-basic acids increase the aq. soly. of NH_3 (they diminish the partial pressure of NH_3), while those of polybasic acids decrease the soly. (by increasing the partial pressure of NH_3). The influence of NH_3 on the aq. soly. of NH_4 salts makes possible the distinguishing of polybasic acids and the sepn. of mono- and polybasic acids, and can be made a criterion between mono- and polybasicity. R. H. ABORN

Calcium phosgeno-aluminate: A physico-chemical study. A. F. O. GERMANN AND C. R. TIMPANY. *J. Phys. Chem.* **29**, 1423-31(1925); cf. *C. A.* **19**, 2920.—The vapor tension, d., and cond. of solns. of various strengths of CaAl_2Cl_6 , the Ca salt of phosgeno-aluminic acid, COAl_2Cl_6 , in COCl_2 were detd. at 0° and 25° for evidence as to the validity of the theory of phosgeno acids and salts. The higher cond. than that of AlCl_3 in COCl_2 was considered positive evidence. A. W. FRANCIS

Phosgeno-aluminates of sodium, strontium, and barium. A. F. O. GERMANN AND

D. M. BIROSEL. *J. Phys. Chem.* **29**, 1469-76(1925); cf. preceding abstr.—Some new phosgeno-aluminates were prepd. Their soly. in COCl_2 and the vapor pressures of these solns. were detd. The following solvates were identified: $3\text{Ba}(\text{AlCl}_4) \cdot 6\text{COCl}_2$, $\text{BaAl}_2\text{Cl}_8 \cdot \text{COCl}_2$, $5\text{SrAl}_2\text{Cl}_8 \cdot 9\text{COCl}_2$, $\text{SrAl}_2\text{Cl}_8 \cdot \text{COCl}_2$. NaAlCl_4 forms no solvate with COCl_2 at 25° . The vapor pressures of the above solvates at 25° were 625, 290, 950, 175 mm. Mol. wt. calcs. indicate 15 to 20 atoms of Sr or Na per mol. Solns. of BaAl_2Cl_8 at room temp. and SrAl_2Cl_8 at 50° sep. into 2 layers, but both have lower crit. soln. temps.

A. W. FRANCIS

Vapor-pressure lowering as a function of the degree of saturation. I. ISAAC BENCOWITZ. *J. Phys. Chem.* **29**, 1432-52(1925).—In considering the properties of solns. it is assumed that the degree of saturation, in cases of substances having a definite soly., e. g., salts in H_2O , is more fundamental than concn. as ordinarily expressed. If the soly. of a salt in H_2O at a given T is n_s g. in 100 g. H_2O , the degree of satn. of a soln. contg. n_1 g. salt in 100 g. H_2O is $S = n_1/n_s$. B. plots the log of vapor pressure lowering at const. S , i. e., $\log(\Delta p)_S = x_1$ vs. $1/T$, and obtains straight lines, so that $d \log(\Delta p)_S = x_1 / d(1/T) = \text{const.}$ Similarly, graphs of $\log(S)_{\Delta p=1}$ vs. $1/T$ yield the relation $d \log(S)_{\Delta p=1} / d(1/T) = \text{const.}$ The relation between $\log \Delta p$ and $1/T$ at various const. values of S yields a family of parallel straight lines, indicating that the slope of these lines is independent of the degree of satn. The complete relationship between Δp , T and S is given by the equation $\log \Delta p = K/T - Ka + (Ka/b) \log S$. K = slope of the $\log(\Delta p)_S = x_1$ vs. $1/T$ curves, a = reciprocal of the T at which the satd. soln. has a vapor pressure lowering of 1 mm. Hg, and b = the intercept of the $\log(S)_{\Delta p=1}$ vs. $1/T$ curve on the $\log S$ axis. For satd. solns. the equation reduces to $\log \Delta p_{\text{satd.}} = K/T - Ka$; hence $\log(\Delta p / \Delta p_{\text{satd.}}) = (Ka/b) \log S$, or the log of the ratio of the vapor pressure lowering at any 2 given degrees of satn. is independent of T . The relations have been tested for 31 salt solns. with data taken from standard sources.

F. C. KRACEK

Selective solvent action. IV. **Cryoscopy in mixed solvents.** ROBERT WRIGHT. *J. Chem. Soc.* **127**, 2334-8(1925); cf. *C. A.* **19**, 428. When a solute is added to a binary mixed solvent in only 1 of whose components it is sol., the f. p. of the constituent in which it is insol. is always raised. When the concn. of the "semi-solute" is plotted against the elevation of the f. p. a continuous curve results with a break at the point of formation of 2 liquid phases. "It thus seems evident that a semi-solute when dissolved in a mixed solvent forms solvates with the constituent in which it is sol., and as a result raises both the f. p. and the vapor pressure of the other constituent." These statements are based on a study of 4 mixed solvents with 2 to 5 semi-solutes for each one. The effect of adding a solute sol. in both constituents of a C_6H_6 -EtOH mixt. was studied for 5 solutes. Solute more sol. in alc. at first raise the f. p. of the C_6H_6 and at higher concns. depress it, while those more sol. in C_6H_6 depress the f. p. of C_6H_6 in all concns. The method is applied also to discriminate between the relative attractions of C_6H_6 and EtOH for 16 third liquids completely miscible with both. The lower members of the fatty alc. series show a greater attraction for EtOH than for C_6H_6 . Those above amyl alc. and aromatic compds. in general all seem to show a greater attraction for C_6H_6 than for EtOH.

F. L. BROWNE

Gas streams in electrolytes. A. COEHN. *Z. Elektrochem.* **31**, 552-4(1925).—In very slightly ionized electrolytes the Hittorff scheme of ionic migration no longer holds with large potential gradient at an electrode, so long as concn. changes are permitted in the neutral electrolyte. Rather there appear free space-charges. The apparent movement, which is observed as directed reflection from the electrode, depends not on any primary movement of gas bubbles, but on the primary action of the ions, of which those drawn into the immediate vicinity of a point-electrode attain a very high velocity, and thereby carry along liquid and gas bubbles.

R. H. ABORN

Ionization of trimethylethoxyammonium hydroxide, trimethylamine oxide and their derivatives. WM. A. NOYKS. *J. Am. Chem. Soc.* **47**, 3025-30(1925); cf. N. and Hibben, *C. A.* **17**, 656; Stewart and Maeser, *C. A.* **19**, 238.—The conclusion of S. and M. that $(\text{Me}_3\text{NOEt})\text{OH}$ and $(\text{Me}_3\text{NOMe})\text{OH}$ are highly ionized in aq. solns. has been confirmed and the erroneous observations of N. and H. have been corrected. Reasons are given for believing that the 5th, polar valence of NH_4 compds. is a real valence residing in the N atom and not in the group as a whole; also, for thinking that the amine oxide retains the structure $\text{Me}_3\text{N}:\ddot{\text{O}}$ in soln., the N having its usual valence of 5 (1 being polar) and O its valence of 2. The hypothesis of S. and M. that the amine oxide has the structure $\text{R}:\text{N}:\ddot{\text{O}}:\text{H}:\ddot{\text{O}}:\text{H}$ in soln. is questioned. Reasons are given for believing that the polar valence of NH_4 compds. is properly considered as a "primary

valence" and that the differences between "polar" and "non-polar" valences are differences of degree rather than of kind.

C. J. WEST

The conductivity of some acids of medium strength, in methanol and their catalytic action. HEINRICH GOLDSCHMIDT AND HARALD AARFLOT. *Z. physik. Chem.* **117**, 312-33(1925); cf. *C. A.* **19**, 1519-20.—The cond. of *trichloroacetic acid*, *trichlorobutyric acid* and *picric acid*, in MeOH and its mixts. with H₂O, are detd. by the method given previously. The affinity consts. and the degrees of dissociation are calcd. according to the theory of Bjerrum, the latter with the aid of the cond. curves of HCl, HBr and HI. Special consideration is given to the quotient k/p_H and to the anticatalytic action of H₂O in esterification. The results are given in extensive tables. J. T. S.

Hydration of ions. J. BABOROVSKY. *Chem. Listy* **19**, 297-300(1925); cf. *C. A.* **18**, 492.—From expts. by A. Wagner, V. Chudarek and J. Velsch (to be published in "Moravska prirodvedcka spolenost") B. calcs. that if H⁺ is monohydrated, the hydration of Cl⁻, Na⁺, K⁺ and Li⁺ corresponds to 6, 22-5, 10 and 35 mols. H₂O, resp.

F. C. KRACEK

The effect of variation in ionic strength on the apparent first and second dissociation constants of carbonic acid. A. BAIRD HASTINGS AND JULIUS SENDROY, JR. *J. Biol. Chem.* **65**, 445-55(1925).—The 1st and 2nd dissociation consts. of H₂CO₃ have been detd. at 38° in solns. of varying ionic strength. When extrapolated to $\mu = 0.0$, the 1st dissociation const. was found to be 4.68×10^{-7} or $p_{K_1} = 6.33$. The activity coeff. of the HCO₃ ion, γ , was found to be related to the ionic strength of the soln. from $\mu = 0.01$ to $\mu = 0.18$ according to the equation $-\log \gamma_1 = 0.5\sqrt{\mu}$. The apparent 1st dissociation const. is related to the ionic strength of the soln. according to the equation $p_{K_1}' = 6.33 - 0.5\sqrt{\mu}$. The 2nd dissociation const. of H₂CO₃ was found to be 6.03×10^{-11} or $p_{K_2} = 10.22$ at 38°. The activity coeff. of the CO₃ ion, γ_2 , was found to be related to the ionic strength of the soln. from $\mu = 0.02$ to $\mu = 0.16$ according to the equation $-\log \gamma_2 = 1.6\sqrt{\mu}$. The apparent 2nd dissociation const. is related to the ionic strength of the soln. according to the equation $p_{K_2}' = 10.22 - 1.1\sqrt{\mu}$. These results are in harmony with the theory of the behavior of strong electrolytes as elaborated by G. N. Lewis, Bronsted, and Debye and Huckel.

A. P. LOTHROP

The velocity of monomolecular reactions. D. ALEXEJEW. *Z. physik. Chem.* **118**, 119-22(1925).—On the assumption that an "activated" mol. decomposes on its first collision with another mol., and that its reaction products contain energy enough to activate only one other mol., the velocity of a first-order gaseous reaction is shown to depend upon the first power of the no. of mols. present. The mechanism of a monomol. decompn. may thus be explained without the assumption of an activation by infra-red radiation.

R. J. HAVIGHURST

The dependence of the velocity of alkaline hydrolysis on the constitution of the alcohol. II. IJENNART SMITH AND HUGO OLSSON. *Z. physik. Chem.* **118**, 99-106(1925); cf. *C. A.* **16**, 4114.—Bimol. velocity consts. have been detd. for the alk. hydrolysis of the following esters: normal, iso-, secondary and tertiary Bu acetate; primary and secondary Pr glycolate. These results, together with those previously obtained, show that the velocity of alk. hydrolysis is a constitutive property, depending upon the alkyl radical of the alc. and upon the constitution of the acid. The influence of the alc. is greater than that of the acid, a confirmation of van't Hoff's idea of the mechanism of sapon. Alk. hydrolysis and ester formation from Ac₂O and alc. show the same relation between constitution of the alc. and velocity of reaction. **III. Dependence of velocity of hydrolysis on temperature.** HUGO OLSSON. *Ibid* 107-13.—Velocities of the above reactions were measured at 0, 10, 20, 30, 40° and the temp. coeff. was found to be const. over the whole series, decreasing slowly with increasing temp.

R. J. HAVIGHURST

The thermal decomposition of nitrogen pentoxide at low pressures. H. S. HIRST AND E. K. RIDEAL. *Proc. Roy. Soc. (London)* **109A**, 526-40(1925); cf. *C. A.* **19**, 3415.—The thermal decompn. of N₂O₅ apparently satisfies the usual criteria of unimol. change. Attempts have been made to interpret the results on the hypothesis that the reaction is in reality of a more complex character. Some of these attempts are critically discussed. New measurements of the reaction velocity at 33.5° and 43.8° were made in an all-glass system. The progress of decompn. at any time was detd. by freezing out the N₂O₄ and NO₂ and measuring the O pressure by means of a Piram-Hale vacuum gage. Neither the Pt wires of the gage nor the glass walls of the app. excited any appreciable effect on the reaction rate. The initial gas pressures were varied from 0.010 to 1.280 mm. of Hg. The data point conclusively to the appearance of a disturbance in the rate of reaction when the total pressure in the reacting system falls

below 0.26 to 0.28 mm. of Hg. The observations are most readily interpreted on the assumption that a definite fraction of the activated mols. always undergoes decompn. irrespective of the pressure, but that a larger fraction (approx. 4/5 of the total) of the activated mols. only undergoes decompn. if they do not, after activation, suffer collision with other mols. during a period of about 10^{-6} sec. If collision does take place within this time, deactivation without decompn. must occur. The rate of decompn. thus increases as pressure decreases, until none of the activated mols. is deactivated by collision. According to this view, the rate of decompn. of N_2O_5 for all pressures is expressed by the equation— $dc/dt = K_1 (1 + K_2 e^{-1.04 l.P/\lambda P_\lambda}) e^{-24.700/RT} .C$, where the expression $e^{-1.04 l.P/\lambda P_\lambda}$ represents the fraction of the active mols. which have a mean free path greater than l at the pressure P . The const. k_1 is the ordinary unimol. const. at high pressures, viz., 4.98×10^{13} , with a sec. as unit of time, and k_2 is another sp. const. detd. by fixing one point on the pressure-velocity const. curve. By a suitable choice of l and k_2 the equation yields values for the velocity const. that are in good agreement with the exptl. data. The decompn. of N_2O_5 is a true unimol. reaction, proceeding at a rate given by the general equation— $dc/dt = ve (-N h\nu/RT) .C$. The mechanism of the reaction cannot involve activation by collision, nor by inflowing radiation, nor by any type of chain reaction, as has been postulated by various investigators in the past.

R. L. D.

Explosions with alkali metals. H. STAUDINGER. *Z. Elektrochem.* 31, 549-52 (1925). The alkali metals act as powerful detonators with org. halogen compds. as follows (the no. is energy in m. kg.): $\text{CH}_3\text{Cl} + \text{KNa}$, 0.15, moderately strong; $\text{CH}_2\text{Cl}_2 + \text{KNa}$, 0.002, strong; $\text{CHCl}_3 + \text{KNa}$, 0.0007, very strong; $\text{CHCl}_3 + \text{Li}$, 1.5, weak; $\text{CHCl}_3 + \text{Na}$, 0.6, moderately strong; $\text{CHCl}_3 + \text{K}$, 0.02, strong; $\text{CH}_2\text{Cl}_2 + \text{K}$, 0.06, moderately strong; $\text{CH}_2\text{Br}_2 + \text{K}$, 0.04, strong; $\text{CH}_2\text{I}_2 + \text{K}$, 0.06, strong. The reactions are considered in terms of theories of mol. formation and predictions are made as to other possible explosive reactions with inorg. halides and with compds. contg. O and S.

GEORGE L. CLARK

Distribution of pyridine between water and benzene. R. M. WOODMAN AND A. S. CORBET. *J. Chem. Soc.* 127, 2461-3.—The 3-component system, water-pyridine-benzene, is an example of a pair of partly miscible liquids. Over the range 0-6% of pyridine in the total system, the ratio of the weight percentages of this liquid in benzene and water is about 2.7 at 25°. The ratio decreases with increasing concn. of pyridine to a min. of 0.8, finally to reach unity at the crit. point. The behavior is unusual and results in a change of direction of the slope of the tie lines.

JAMES M. BELL

System, water and the nitrates and sulfates of ammonium and potassium at 25°. YUKICHI OSAKA AND RYOHEI INOUE. *Japn. J. Chem.* 2, 87-98 (1925). [In English.]—The equil. of the system $(\text{NH}_4)_2\text{SO}_4 + 2\text{KNO}_3 \rightleftharpoons 2\text{NH}_4\text{NO}_3 + \text{K}_2\text{SO}_4$ is reported at 25°. The solid phases existing in this system are all solid solns. of the following types: $(\text{NH}_4\text{K})_2\text{SO}_4$, a complete series with no gap; $(\text{NH}_4\text{K})_2(\text{NO}_3)_2$, 2 series with a gap, which extends from 15.6 to 65 mol. % of NH_4NO_3 ; they are distinguished as α - and β -series. $(\text{NH}_4\text{K})_2 0.5\text{SO}_4 \cdot 0.5(\text{NO}_3)_2$, this solid soln. extends from the double salt $(\text{NH}_4)_2 0.5\text{SO}_4 \cdot 0.5\text{NO}_3$ to the solid soln. of the approx. formula $(0.6\text{NH}_4, 0.4\text{K})_2 0.5\text{SO}_4 \cdot 0.5(\text{NO}_3)_2$. $(\text{NH}_4\text{K})_2 0.4\text{SO}_4 \cdot 0.6(\text{NO}_3)_2$, this solid soln. extends from the double salt $(\text{NH}_4)_2 0.4\text{SO}_4 \cdot 0.6(\text{NO}_3)_2$ to the solid soln. of the approx. formula $(0.865\text{NH}_4, 0.135\text{K})_2 0.4\text{SO}_4 \cdot 0.6(\text{NO}_3)_2$. The data are given in a series of tables and diagrams.

C. J. WEST

Studies upon catalytic combustion. I. The union of carbon monoxide and oxygen in contact with a gold surface. WM. A. BONE AND G. W. ANDREW. *Proc. Roy. Soc. (London)* 109A, 459-76 (1925); cf. *Trans. Roy. Soc. London (A)* 206, 1 (1906).—The catalytic combination of CO and O on a Au wire gauze (wt. 52.5 g., exposed surface about 445 sq. cm.) at about 300° and pressures below 1 atm. was studied by a static method. The gauze catalyst was placed in an all-glass app., and the section that contained the catalyst was heated in a combustion-tube furnace. A charge of mixed CO and O gas of the desired compn. was introduced and continuously circulated over the catalyst. The circulation was accomplished by an automatic Sprengel pump in such a way that the cycle included (1) satn. with H_2O at 25°, (2) passage through the heated catalyst, and (3) scrubbing with baryta water. The rate of the reaction was measured by observing the pressure decrease in the system. The gas mixts. used contained CO and O in the proportions $2\text{CO}/1\text{O}_2$, $1\text{CO}/1\text{O}_2$, and $4\text{CO}/1\text{O}_2$. The final const. rate of reaction attained with the $2\text{CO}/1\text{O}_2$ mixt. after prolonged operation was regarded as the "normal" activity and was used as the reference state to which the catalyst was always brought before a new set of conditions was investigated. A dependence of reaction rate on the presence of moisture was indicated, but not closely examd. The

rate of combination of a moist $2\text{CO}/10_2$ mixt. in contact with the Au surface in the normal state of activity at about 300° was directly proportional to the pressure of the gas mixt. The normal catalytic activity of the catalyst could be greatly diminished either (1) by cooling the catalyst down to, and keeping it for some time at, room temp. or (2) by evacuating it at the reaction temp. The reattainment of normal activity after such treatment required many hrs.' operation in the $2\text{CO}/10_2$ mixt. The activity of the catalyst could be increased by previous exposure to either CO or O at 300° . With the gas mixts. $1\text{CO}/10_2$ and $4\text{CO}/10_2$ the rate of reaction was always proportional to the partial pressure of CO. The results are best explained by assuming an "activation" of both gases through association with the surface. The activation is not confined to superficially adsorbed gas films of monomol. thickness, but extends to more deeply occluded gases. The results are critically discussed in reference to their bearing on the Langmuir (cf. *C. A.* 10, 3007) and the Taylor (cf. *C. A.* 19, 2442) theories of heterogeneous catalysis.

R. L. DODGE

Studies on catalysis by nitroamide. II. The catalysis of the simple amino bases. J. N. BRONSTED AND HANS C. DUUS. *Z. physik. Chem.* 117, 299-311(1925), cf. *C. A.* 19, 430.—The bases *aniline*, *o*-, *m*-, *p*-*toluidine* and *o*-, *m*-, *p*-*chloroaniline* are investigated in 3 series of expts. The H ion concn. of their mixtures with stoichiometrically insufficient quantities of HCl or HClO_4 is detd. electrometrically and by the method of Bredig (catalysis of the decompn. of ethyl diazo acetate) and from these detns. the base consts. are calcd. The app. and methods are described. In the same app. the catalysis const. k for the reaction $\text{NO}_2\text{NH}_2 = \text{N}_2\text{O} + \text{H}_2\text{O}$ is detd. The relation $k = G \times K_b^{0.83}$ holds between both consts., where G is a const.

JOHN T. STERN

The catalysis by alumina of the reaction between ethyl alcohol and ammonia. G. W. DORRELL. *J. Chem. Soc.* 127, 2399-407(1925).— Al_2O_3 was chosen as catalyst because it has very little dehydrogenating action on alc. Gas streams of NH_3 and of N_2 contg. EtOH vapor were mixed, preheated, and passed over the Al_2O_3 . The total amt. of NH_3 converted to amines was detd. by absorption from the emerging gases and analysis. No attempt was made to distinguish between primary, secondary and tertiary amines. The optimum temp. for the reaction is about 300° , the conversion being less at higher or lower temp. The reaction proceeds best when the speed of the gases passing over the catalyst is not too slow. The lower yields at low speeds are due to decompn. of the amines formed. The effect of using an excess of EtOH over NH_3 is to produce larger amts. of secondary and tertiary amines. EtNH_2 decomposes under the conditions of the main reaction. NH_3 is not decomposed to any measurable extent by the catalyst. Al_2O_3 adsorbs NH_3 readily and a table is given showing the relation between the amt. of NH_3 adsorbed and the time of flow of the NH_3 over the catalyst. No sign of catalytic poisoning could be detected.

F. L. BROWNE

Gallium-in-quartz thermometer graduated to 1000° . SYLVESTER BOYER. *Ind. Eng. Chem.* 17, 1252-3(1925).—In developing the thermometer described, numerous characteristics of Ga and of quartz were discovered. Thus, highly purified Ga under 2-3 microns pressure can be cooled to -15° to -20° before solidifying, but traces of Bi raise the f. p. greatly. The tendency of Ga to wet quartz is increased by Zn and by As, but not by In or by Pb. The best protective coating in etching quartz with HF was China wood oil.

C. C. DAVIS

White and black diamonds and their relation to carbon. W. A. ROTH AND W. NAESER. *Z. Elektrochem.* 31, 461-6(1925).—The heats of transformation of white diamonds to α and β graphite (41 cal./g. and 16 cal./g., resp.) are calcd. from the heats of combustion measured in a micro bomb calorimeter. These values may be in error 10% and 20%, resp. The heats of combustion are given: of diamond 7876 ± 3 cal.; α graphite 7832 cal.; β graphite 7856 cal.; carbonado (black diamond) 7884 ± 2 cal. The heat of combustion of carbonado, being higher than that of white diamond, indicates that it is composed of diamond with amorphous C (heat of combustion about 8060).

E. R. SCHIERZ

Apparent molecular heat and viscosity of solutions of naphthalene in organic solvents. NICOLAS DE KOLOSOSKII. *Bull. soc. chim. Belg.* 34, 221-31(1925).—Viscosities of solns. of C_{10}H_8 in C_6H_6 , CCl_4 , etc., have been detd. and the available sp. heat data for these solns. have been recalcd. A simplified form of K.'s general equation for the sp. heat of solns. (cf. *C. A.* 19, 3050) is applied to these data, the conclusion being reached that the apparent mol. heat of a dissolved substance is equal to its actual mol. heat plus the heat equiv. of the work done against the viscosity of the soln. during a rise in temp. of 1° .

WM. B. PLUMMER

A thermodynamic consideration of the synthetic methanol process. K. K. KELLEY. *Ind. Eng. Chem.* 18, 78(1926).—The free energy and equil. const. of the reaction

$\text{CO} + 2 \text{H}_2 = \text{CH}_3\text{OH}(\text{g})$ are calcd. at various temps. $\Delta F_{298}^0 = -10.950$, $\Delta F_{623}^0 = 0$, the working limit of the process at 100 atm. is 700°Abs . The method of calcul. is that of Lewis and Randall. Park's value for the entropy of liquid CH_3OH is assumed.

F. R. B.

The influence of mechanical processes on the variation of electrical resistance with temperature of nickel. S. DE NEGRI. *Nuovo cimento* [N. S.] 2, 275-85(1925).—The variation of elec. resistance of Ni when submitted to a process of deformation has been measured over the temp. interval of $0-600^\circ$. Ni wire was wound noninductively about a quartz tube, heated in an elec. furnace and the resistance detd. with a Wheatstone bridge arrangement. These expts. demonstrate a complete equivalence of values for a given temp. through repeated cycles of heating. Drawing causes a diminution of the ratio $(R_t - R_0)/R_0$ compared to normal Ni and is more marked the greater the degree of deformation produced. Mech. deformation does not affect the Curie point.

L. T. FAIRHALL.

Passivity of iron by dilute nitric acid. TADAYOSHI FUJIHARA. *Ind. Eng. Chem.* 18, 62-3(1926).—Dil. HNO_3 (2-10%) in alc. soln. makes Fe passive in moist air, free from CO_2 . The oxide formed is FeO . This gives with H_2O alk. $\text{Fe}(\text{OH})_2$, which forms the protective coating.

H. S. VAN KLOOSTER

Glaser's experiments and the orientation of the molecules in a magnetic field. G. BREIT. *J. Wash. Acad. Sci.* 15, 429-34(1925).—Glaser has shown that the diamagnetic susceptibilities of H_2 , N_2 and CO_2 are proportional to the pressure if that be sufficiently high or sufficiently low, but that there is a transition region in which the relation between susceptibility and pressure is non-linear. The suggestion of Glaser and Debye that this is due to the finite time required for space quantization of the mols. to be established is examd. by Breit and a no. of possibilities are investigated. The paper is highly mathematical.

W. W. STIFLER

The mechanically enforced double refraction of amorphous liquids in relation to the molecular form. D. VORLÄNDER AND ROBERT WALTER. *Z. physik. Chem.* 118, 1-30(1925); cf. *C. A.* 19, 1810.—The liquid to be investigated fills the space between 2 concentric cylinders, and is made anisotropic by a mech. force due to the rapid rotation of the inner cylinder. Measurements are given on the double refraction of 135 amorphous liquids (as distinguished from cryst. liquids and colloidal solns.). With the app. used, it was impossible to detect double refraction in liquids with viscosity less than $5(\text{H}_2\text{O} = 1)$.

S. C. LIND

The measurement of radioactivity. CAMILLE MATIGNON AND G. MARCHAL. *Chimie et industrie* **14**, 503-10(1925).—Detailed description of the methods of detg. radioactivity by means of α -rays, of emanation, and of γ -rays. A. P.-C.

The effect of the chemical bond on the energy of intraatomic levels. RITA BRUNETTI. *Atti accad. lincei* [6] **2**, 323-8 (1925).—A mathematical phys. paper.

E. J. WITZEMANN

Spectra and atomic structure. S. GOUDSMIT. *Physica* **5**, 281-92(1925).—A review pertaining to the validity of the Zeeman effect limitation rules of Landé and the interpretation of them by Pauli (*C. A.* **19**, 2450). Pauli's rules (quantum nos. are exclusively assigned to the electrons, each electron having an individual combination) lead to the Bohr-Stoner periodic system. A bibliography is given. B. J. C. v. D. H.

Disintegration of atomic nuclei. E. RUTHERFORD. *Nature* **115**, 493-4(1925).—A short review of recent work on the mechanism of collisions of α -particles with atomic nuclei, and the fate of the bombarding α -particles (cf. *C. A.* **17**, 3449; **18**, 2104; **19**, 1655).

FLORENCE N. SCHOTT

The triangular systems of Rutherford-Bohr in relative equilibrium. U. CRUDELI. *Nuovo cimento* [N. S.] **2**, 225-34(1925).—A mathematical treatment of these systems and derivation of the relation between charge and mass. The necessary conditions are defined for the existence of a given system in uniform rotating motion. L. T. F.

High-frequency rays of cosmic origin. R. A. MILLIKAN. *Science* **62**, 445-8 (1925).—A summarizing report on the results of the investigation of the "penetrating" cosmic radiation. Judging from the extraordinary penetrating ability (equiv. to 68 feet of water or 6 feet of lead), these rays must possess a frequency about 1000 times the mean frequency of X-rays. They are not homogeneous. Absorption calcs. show that the wave lengths range from 0.0004 A. U. to 0.00067 A. U. Upon striking matter they stimulate a softer radiation, the frequency of which is in agreement with the theory of the Compton effect. Since the most penetrating rays known hitherto, the γ -rays of Th and Ra, are produced by nuclear changes within the atom, it is assumed that the new rays are produced all through space by a similar process involving enormously greater energetic changes (about 50 times as great as in radioactive processes). The computable frequency of a radiation produced when He is formed out of H, or when an electron is captured by a positive nucleus, would correspond with the observed frequency of these rays. They might also be produced by electrons possessing the speed of light. The latter hypothesis would account for the negative charge of the earth, but is in a contrast with the quant. variation of ionization in closed vessels in various altitudes. The fact that the rays hit the earth from all directions, day and night, is explained by the transparency of matter for these extremely hard rays and the assumption that they could originate in the very distant spiral nebulae. E. K.

Self-diffusion in solid metals. G. VON HEVESY AND A. OBRUSHEVA. *Nature* **115**, 674-5(1925); cf. *C. A.* **15**, 3921.—Two thin foils, one of ordinary lead, the other with lead contg. Th B in homogeneous mixt., were pressed together *in vacuo*. The rate of self-diffusion of radioactive lead into inactive lead was measured by comparing the number of scintillations on the observing screen of the α -particles due to the diffused atoms or their successive products of disintegration with the number of scintillations produced by the active foil at the beginning of the expt. The values for 260° and 324° are 6×10^{-7} and 1.4×10^{-4} cm.² day⁻¹, resp. Values for intermediate temps. are given. The diffusion rate 2° below the m. p. is thus only 10,000 times smaller than in molten lead. The coeff. of diffusion of Th B into the crystal lattice of a single lead crystal even at a temp. just below the m. p. is less than 10^{-8} cm.² day⁻¹. Coeffs. of diffusion of two very similar metals are analogous to those obtained in self-diffusion—that of Pb in Tl at 285° being 2×10^{-8} cm.² day⁻¹. Coeffs. of diffusion of Po into Pb foils and single crystals were found to be about the same. At 310°, $D = 1.3 \times 10^{-8}$ cm.² day⁻¹. The atoms of Po thus loosen the lattice of the individual Pb crystals and diffuse as if through amorphous lead.

FLORENCE N. SCHOTT

Polymerization of acetylene under the influence of α -particles. W. MUND AND W. KOCH. *Bull. soc. chim. Belg.* **34**, 241-55(1925).—The rate of polymerization of C₂H₂ contg. approx. 5×10^{-4} % of Rn has been detd. It is found that each α -particle causes the disappearance of 4.36×10^6 mols. of C₂H₂. Since the no. of gaseous ions produced by an α -particle in C₂H₂ is 2.13×10^6 , 20.5 mols. disappear for each ion pair formed.

WM. B. PLUMMER

The determination of radium by the γ -rays. D. GIOVANNI COSTANZO. *Mem. real acad. ciencias y artes.* **19**, 147–52(1925).—The amt., x , of Ra in a sample which is in radioactive equil. is commonly detd. by comparing the ionization current produced by the γ -rays, principally from Ra C, with that produced by a standard sample contg. p g. Ra. Both the sample and the standard are placed in the same position relative to the electroscope, and this position is chosen so that the time of discharge of the electroscope for the standard, t_p , may be measured with the desired accuracy. The amt. of Ra in the unknown is, $x = p(t_p/l_x)$; and the max. precision in the value of x is attained when t_p and l_x can be detd. with a precision of the same order, i. e., when $p/x = 1$. However, this precision is not attained if x is much greater or much smaller than p . In this case, greater precision is attainable by comparing the ionization currents of x and $(x + p)$, or of p and $(x + p)$, resp. Then, $x = (p(l_{(p+x)} - (t_x - t_{(p+x)}))) / (t_x - t_{(p+x)})$, and $(p + x) = p l_p / t_{(p+x)}$, resp. Two samples contg. (1) 6.92 mg., and (2) 0.634 mg. Ra were compared by this method with deviations of 0.00 mg. and 0.000 mg. But, when (1) was compared directly with (2) as the standard, deviations of 0.62 mg. and 0.78 mg. in the value of (1) resulted; and comparison of (2) directly with (1) as the standard gave deviations of 0.013 mg. and 0.080 mg. in the value of (2). This improved method is used in the Official Lab. of Radio activity of Lisbon.

R. H. LOMBARD

Replacement of the hypothesis of unmechanical coercion by a requirement for the internal condition of every electron. G. E. UHLENBECK AND S. GOUDSMIT. *Naturwissenschaften* **13**, 953–4(1925).—One difficulty, pointed out by Heisenberg (*C. A.* **19**, 3064) remains in the explanation of the Zeeman effect according to Pauli's rules: the occurrence of a relativistic doublet in the X-ray and the alkali metal spectrum. It is now proposed to assign 4 degrees of freedom to every electron corresponding to the 4 quantum nos. (n and k and R are main, azimuthal and rotational quantum nos. resp. for the electron; the others have the usual significance). In order to explain the magnetic inactivity of the atom residue (absence of relativistic difference between light and heavy alkali metals) it is necessary to assume for the electron model that the ratio magnetic moment/mechanical moment for its own rotation has a value double that for the orbital motion. From the orientation of R relative to the orbital plane the relativistic doublets can then probably be explained (cf. Wentzel's rules, *C. A.* **19**, 2913).

B. J. C. VAN DER HOEVEN

The emission current in a triode. B. D. H. TELLEGEN. *Physica* **5**, 301–15(1925).—A method is given for the calcn. of the current to the cathode of a parallel plane triode, taking into account the space charge effect. By neglecting the space charge between grid and anode the result is greatly simplified and can then be extended to the case of cylindrical electrodes, leading to an equation previously found by Schottky.

B. J. C. VAN DER HOEVEN

The absorption of cathode rays in aluminium. B. F. J. SCHONLAND. *Nature* **115**, 497(1925).—S. attributes the difference between the results obtained by Terrill (*C. A.* **19**, 602) and his own (*C. A.* **18**, 17) in the measurement of the variation in the fraction of a beam of cathode rays transmitted by an Al foil when the velocity of the rays is varied to errors in the measurements of the fraction transmitted. F. N. S.

Effect of an alternating magnetic field on the polarization of the resonance radiation of mercury vapor. E. FERMI AND F. RASETTI. *Nature* **115**, 764(1925); cf. *C. A.* **19**, 779, 780.—F. and R. observed a strong increase of the polarization in passing from a frequency of $1.5 \times 10_6$ to one of $5 \times 10_6$, though the amplitude of the field remained const.

FLORENCE N. SCHOTT

The spark spectrum of tungsten in a helium vacuum arc. H. B. LEMON. *Nature* **115**, 802(1925); cf. *C. A.* **19**, 776.—A hot W cathode used in the operation of an arc at low pressure in pure He is capable of developing the spark spectrum of W instead of the arc spectrum. The lines make their appearance when the filament is raised to dazzling incandescence either by the thermionic bombardment of the He, or by a direct heating current, or preferably, by both. This method will enable the spark spectra of refractory metals in He vacuum arc conditions to be used with greater reliability.

FLORENCE N. SCHOTT

Multiple cathodes and the origin of canal rays. R. MAGINI. *Nuovo cimento* [*N. S.*] **2**, 235–73(1925).—M. has analyzed the appearance of cathode rays as influenced by varying degrees of rarefaction and the effect of magnetic and elec. fields. High rarefaction has but little appreciable effect upon the emission of cathode rays. Excitation of the double cathode is limited to the central part of the bundle of rays and is retarded by rarefaction. Expts. apparently indicate that the initial velocity of the cathode rays is low and that the electrons forming the track do not strike the

cathode. Every modification produced in the track of the cathode rays by magnetic or elec. fields is reflected in equal measure in the brush of canal rays. The angle of deviation of these rays increases with diminishing distance from the cathode and their direction becomes much inclined from the plane of the latter. L. T. FAIRHALL

A modified ionization chamber. ARCIERO BERNINI. *Nuovo cimento* [N. S.] **2**, 305-13(1925).—The modified ionization chamber permits measurement of ionization effects of great magnitude without any decrease of precision. L. T. FAIRHALL

A new method for the study of soft X-rays. G. K. ROLLEFSON and E. J. POTH. *Science* **62**, 497-8(1925).—A beam of electrons, having velocities uniformly distributed over the range under investigation (100-750 v.) is spread into a band by means of a magnetic field. Photographic plates exposed to such a band show sharp discontinuities when developed. The photographic emulsions contain the following elements, which have crit. potentials within the range studied: C, N and O in the gelatin; and Ag and Br as AgBr. Following are interpreted discontinuities in order from 135 to 762 v.: Br, $4_1 \rightleftharpoons 3_2$; Br M_{III}; Br M_{II}; C, K α ; Br, M_I; C K abs; Ag, $4_2 \rightleftharpoons 3_3$; Ag M_V; N K α ; Ag M_{IV}; N K abs; O K α ; O K abs; Ag $4_3 \rightleftharpoons 3_2$; Ag M_{III}; Ag M_{II}; Ag $4_2 \rightleftharpoons 3_1$; Ag M_I. GEORGE L. CLARK

Double impacts by electrons in helium. GEORGE GLOCKLER. *Nature* **115**, 909-10 (1925); cf. *C. A.* **19**, 1373. In the measurement of the critical potentials of He, Dymond finds a difference of 20.9 v. between the first and second kink in the current potential curve, and not 20.55 v. as would be expected if the first kink corresponded to electrons which have caused the transition 1S-2s (type A), and the second kink to electrons which have caused two transitions 1S-2S and 1S-2s (type B₁). Dymond assumes that in his app. the second kink is due to the transition BB. G. states reason for believing the double impacts are of the type B₁ or AA rather than BB. He attributes the difference of 0.35 v. in the two different expts. to the energy lost by elastic impacts. FLORENCE N. SCHOTT

Double impacts by electrons in helium. E. G. DYMOND. *Nature* **115**, 910(1925).—D. disagrees with Glockler's explanation (cf. preceding abstr.) that the loss of energy from elastic collisions in his type of app. can result in a sensible error in the values of the excitation potentials of He. Inspection of D's. differential curves show a max. possible error of 0.1 v. FLORENCE N. SCHOTT

The coherence of superposed X-radiations. C. G. BARKLA AND GLADYS I. MACKENZIE. *Nature* **115**, 942(1925); cf. *C. A.* **19**, 2450.—Investigation of the J phenomenon shows that two X-radiations of differing penetrating powers exhibit the J₂ discontinuity at differing filtering thicknesses of Al. These, when superposed, exhibit not two discontinuities at these thicknesses, but one discontinuity of double magnitude (i. e., unaltered relative magnitude) at a thickness between the two shown by its constituents. The discontinuity occurs at a definite absorption coeff. for the whole beam, not at a certain wave length. A long series of expts. gave a remarkably const. magnitude of these discontinuities, viz., a drop of $7.7 \pm 0.5\%$ consistently. The three discontinuities J₁, J₂ and J₃ can be shown one after the other by progressive filtering of a selected X-radiation. Each is indicated by a drop of about 10% in the intensity of the radiation as usually measured. FLORENCE N. SCHOTT

Unsteady phenomena in diffraction spectra. EBERHARD BUCHWALD. *Physik. Z.* **26**, 672-5(1925). W. F. MEGGERS

The theory of the continuous Röntgen spectrum. M. BRONSTEIN. *Z. Physik* **32**, 881-5(1925).—The quantum-theoretical consideration of the elementary process in radiation of the continuous Röntgen spectrum leads to the conclusion that the sharp limit of the spectrum shifts toward longer waves as the angle between the Röntgen rays and the direction of the cathode rays increases. This effect is extremely small, (<0.1X.E.); its reality can be established only by very accurate measurements. W. F. MEGGERS

Spectroscopic phenomena of the high-current arc. A. S. KING. *Astrophys. J.* **62**, 238-64(1925).—The d. c. arc carrying 1000 amp. or more at about 100 v., usually between rods of small diam., gave a source of great brilliancy and somewhat explosive character, producing mainly the spectrum of the neutral atom under conditions of high excitation. The spectra studied were those of Fe from 2800 to 8400 Å. U. and selected

regions of Ti, Mg, Ca, Cu and Al. Certain lines of Na, Ga, O and N also are described. The distinctive features are an intensification of the high-temp. lines, and a strong development of widening phenomena, with dissymmetries toward red or violet which often result in distinct shifts of the emission lines. Reversals are numerous, becoming less frequent with increasing wave length, but extending into the infra-red of the Fe spectrum. Band spectra are absent in emission but may appear in absorption. A continuous spectrum appears in the ultra-violet, resembling that of the condensed spark and of exploded wires. The high-temp. and explosive action of the arc produced finely divided residues of iron and iron oxide which were examd. microscopically. The degrees of widening, usually unsymmetrical, are given for 920 Fe lines from 4250 to 8400 Å. U. This material permits a selection of lines which remain stable in the ordinary arc and are suitable for wave-length standards. As the members of a multiplet show similar widening in the high-current arc, the selection of series groups is facilitated. Energy level is indicated by the degree of dissymmetry, lines of low level being nearly symmetrical, while the lines of multiplets starting from successively higher levels show increasing susceptibility to unsymmetrical widening. The type of widening shows a close relation to the temp. classification, and for the high-temp. lines the results supplement those of electric-furnace investigations. The other spectra studied showed similar effects to those of the Fe spectrum.

W. F. MEGGERS

The infra-red spectrum of the calcium arc in vacuo. O. SANDVIK AND B. J. SPENCE. *Astrophys. J.* **62**, 265-9 (1925).—This investigation was undertaken to study the arc *in vacuo* as a source of radiation for radiometric examn. of its spectrum, to study possible differences between the spectrum of the arc *in vacuo* and at atm. pressure, and to measure the wave lengths of new lines if they were found to exist. A very steady source of radiation for radiometric observation was developed, the arc being operated with 15 amp. from 220 v., in a pressure of 1 cm. Hg. With the aid of a grating spectrometer and sensitive radiometer the spectral range 8497 Å. U. to 20673 Å. U. was investigated. The wave lengths of 30 lines, 17 of which are new, were measured with an accuracy of 1 or 2 Å. U. Comparison with the observations of Paschen and of Randall for the open arc show certain differences, mainly in intensity, between the arc *in vacuo* and at atm. pressure.

W. F. MEGGERS

Some rules of spectral structure. OTTO LAPORTE AND WM. F. MEGGERS. *J. Optical Soc. Am.* **11**, 459-64 (1925).—By dividing the "transition series" of elements between A and Cu or between Kr and Ag into two groups of 5 there is brought into evidence for elements in each column a remarkable similarity of the positions of the terms in the energy diagrams and the identity of the quantum nos. of the normal states. The *raies ultimes* are the most sensitive spectral lines for detecting chem. elements; it is a generalization that these *raies ultimes* are combinations of the lowest term with the first higher non-metastable term of the same series system, definite preference being shown for $\Delta l = -1$ even if the energy difference is somewhat larger than for other strong combinations involving the lowest term, provided that this difference is not exceptionally great so that the preference is overwhelmed by a closer combination. A resonance line results from an electron jump which involves the lowest term and gives rise to the line of greatest wave length; this line in any spectrum is a combination (usually with $\Delta l = -1$) of the lowest term with a term of the highest multiplicity in the spectrum.

W. F. MEGGERS

The fine structure of hydrogen lines. G. HANSEN. *Physik. Z.* **26**, 678-80 (1925).—The structure of H lines is the simplest observable example of relativistic fine structure and although frequently measured the earlier observations are open to objection. The measurements are repeated and special attention is given to all sources of error. Spectrum tubes contg. 0.04 mm. or less of electrolytic H were cooled in liquid air and operated with direct current. Lummer-Gehrcke plates were used to analyze H_{α} ; the photographic plates, each recording 8 or more spectral orders, were examd. by a registering photometer. The lines α , β , γ show a progressive increase in sepn. of their components as required by theory.

W. F. MEGGERS

New results of fine-structure investigation. E. GEHRCKE. *Physik. Z.* **26**, 675-7 (1925).—Without essentially changing the total width of H_{α} it is possible by altering conditions to change the relative intensities of its two main components which are sepd. by $\Delta\lambda = 0.128$ Å. U. or $\Delta\nu = 0.296$ cm⁻¹. The fine structure of the He spark line 4686 Å. U. has been re-examd. and indicates a sepn. of $\Delta\nu = 0.301$ cm⁻¹ for H, whereas Sommerfeld's theory requires $\Delta\nu = 0.365$ cm⁻¹.

W. F. MEGGERS

The flame spectra of carbon monoxide and water gas. II. F. R. WESTON. *Proc. Roy. Soc. (London)* **109A**, 523-6 (1925).—Further expts. in which flames of CO, H₂ or mixts. of the two in detd. proportions were maintained in an atm. rich in O₂

immediately in front of the slit of a spectrograph have confirmed and extended the conclusions about the mechanism of CO combustion which were set forth in the previous paper (cf. *C. A.* 19, 3427).

W. F. MEGGERS

Infra-red absorption spectra. Solutions of nitrogen pentoxide and nitrogen tetroxide in organic liquids. FARRINGTON DANIELS. *J. Am. Chem. Soc.* 47, 2856-66(1925).—A spectrometer, with Nernst lamp glowler as source and thermopile as detector, was used to det. absorption spectra between 2μ and 7μ of CCl_4 , CHCl_3 , $\text{C}_2\text{H}_2\text{Cl}_2$, $\text{C}_2\text{H}_2\text{Cl}_4$, CS_2 , CH_3NO_2 , $(\text{CH}_3)_2\text{CHBr}$, Bu_2O , and the absorption spectrum of N_2O_5 in each of these solvents was then examd. No shift of absorption max. could be detected in the different solvents. These measurements fail to confirm the predictions of the radiation hypothesis according to which the temp. coeff. of reaction velocity should permit a calcn. of the effective radiation which is supposed to cause the reaction. The absorption spectrum of N_2O_4 was detd. in each of these solvents and the absorption max. showed an appreciable shift from 5.65μ in the gas phase to 5.45 – 5.30μ in soln.

W. F. M.

The Stark effect for $\text{H}\beta$ and $\text{He } \gamma$ 4686. J. S. FOSTER. *Astrophys. J.* 62, 229-37 (1925).—This paper presents exptl. evidence in support of a suggested explanation of the appearance of certain components in Stark's analysis of $\text{H}\beta$ which are questioned by theory. With an exptl. arrangement described before (*C. A.* 19, 1814), the components of $\text{H}\beta$ under fine analysis are measured in various fields up to 47 kv./cm. Theoretically unexpected components of this line are present in one of the analyses reproduced, and absent in another. From known variations in the character of the sources and observations on He mixed with the H_2 , it is proved that the source which gave the spurious components was confused and that the applied field was not in the same direction for all atoms. Consequently the p and s components could not be sepd. completely. The most prominent of the doubtful components, $p \neq 4$, are found to be due to the very strong components $s \approx 4$. It is suggested that in the expts. by Stark the space charge may have been sufficient to cause a similar confusion. At least 3 components of the He λ 4686 line in fine analysis of the Stark effect are clear in an accompanying photograph. The observed spacings are 0.37 and 0.39 A. U., the calcd. value being 0.33 A. U. in each case. Further measurements are prevented by H_2 band lines.

W. F. MEGGERS

Further studies on the Stark effect in hydrogen. MASAZO KIUTI. *Japn. J. Physics* 4, 13-38(1925).—K has found exptl. the s -components $\Delta = \pm 5$ and ± 6 of $\text{H}\alpha$ which were predicted by Kramers from the standpoint of the principle of correspondence. The p -components $\Delta = \pm 8$, which were also predicted, seem to exist too, but with far less intensities. In the case of $\text{H}\beta$, Kiuti's observations agree with the theory of Kramers rather than with the original observation of Stark. The apparent central components both in p - and s -vibrations lie 0.5 A. U. apart on the red side of $\text{H}\beta$ and may be considered to belong to the many-lined spectrum. This point has been tested further by expts. with H_2O vapor as the discharge medium, in which the many-lined spectrum has been very weak. The 2nd-order effect of $\text{H}\gamma$ has been measured for main components up to a field strength of about 290,000 v./cm. The results roughly accord with the theory, but there cannot be overlooked a general deviation of the exptl. from the theoretical results toward the larger values. To interpret this deviation K. calcd. the 3rd-order term but the effect of this term was found to enlarge the deviation. The effect of the variability of the mass of the electron occurs in the sense favorable to the reconciliation but is not sufficiently large. As to the many-lined spectrum, 3 pairs of lines, 5055.08 and 5030.37; 4763.82 and 4740.98; 4253.30 and 4233.60, could be sorted out by their conspicuous Stark effects. The effects are interesting in that each line is accompanied by an isolated component and in that, while 2 different figures are obtained for the p - and s -vibrations in the case of the more refrangible members of the pairs, these 2 appear simultaneously both in p - and s -vibrations in the case of the less refrangible members. Some regularity in the arrangement of these lines is shown. The Stark effects of the Fulcher bands and other lines of the many-sided spectrum are given more completely than in the 1st paper.

C. J. WEST

Intensity relations of the doublets in the main series of the alkali metals. HANS JAKOB. *Naturwissenschaften* 13, 906-7(1925).—The Burger-Dorgelo rule of 2:1 intensity in the doublets of the alkali metals was confirmed on doublets $1s$ – $3p$ of K, Rb and Cs; $1s$ – $4p$ of Cs. Selective absorptive effects in the incandescent vapor were eliminated by using an oxy-hydrogen flame of only 1 cm. thickness and by low salt concns. in the flame. The error in the intensity measurements was 3%.

B. J. C. VAN DER HORVEN

Optical examination of sulfurous acid and its alkali salts: particularly potassium and ammonium pyrosulfite. R. DIETZEL AND S. GALANOS. *Z. Elektrochem.* 31,

466-74(1925).—By comparing the absorption spectra of gaseous SO_2 and solns. of SO_2 , K_2SO_3 , Na_2SO_3 , $(\text{NH}_4)_2\text{SO}_3$, NaHSO_3 , NH_4HSO_3 , $\text{K}_2\text{S}_2\text{O}_6$, and $(\text{NH}_4)_2\text{S}_2\text{O}_6$ separately in H_2O and in EtOH D. and G. detd. the equil. which exists in these solns. An aq. soln. of SO_2 contains SO_2 and $\text{SO}_2 \cdot \text{H}_2\text{O}$, which are responsible for the selective absorption, with only small quantities of H_2SO_3 or its ions. The comparatively greater absorptive power of alc. solns. of this gas is probably due to the formation of alcoholates. Aq. solns. of the alkali bisulfites indicate equil. similar to those for solns. of SO_2 . Aq. and alc. solns. of $\text{K}_2\text{S}_2\text{O}_6$ and $(\text{NH}_4)_2\text{S}_2\text{O}_6$ do not show the characteristic absorption of (S_2O_6) ion. The spectra coincide with those of the alkali bisulfites, indicating hydrolysis to the bisulfite. The change of light absorption observed in solns. of bisulfite and pyrosulfite on standing or solation and termed by its discoverer the "time phenomenon" is explained by D. and G. as a photooxidation of HSO_3 to SO_4 , H_2SO_3 , and $\text{SO}_2 \cdot \text{H}_2\text{O}$. Beer's law does not hold for aq. solns. of SO_2 , alkali bisulfites or pyrosulfites, but does obtain in alc. solns. of SO_2 and aq. solns. of Na_2SO_3 .

E. R. SCHIERZ

Physical properties of some isomeric ethylenes. J. FERRERA and VICTOR HENRI. *Compt. rend.* **181**, 548-50(1925). The ultra-violet absorption spectra of the *cis* and *trans* derivs. of $(\text{:CHCl})_2$, EtCH:CHBr , MeCH:CHBr , and CHCl:CHI were studied. These were compared with the results of other authors upon $(\text{:CHCOOH})_2$, HOOCCH:CH(Me)COOH , MeCH:CHCN , and MeCH:CHCOOH . In all but the last two systems, whose constitution is unknown, the *trans* isomer has greater absorption and higher n than the *cis*. This is taken as evidence that in these two systems, the solid crotonic acid (m. 72°) and its nitrile (m. 108°) are *trans* isomers.

A. W. FRANCIS

Luminescence of solid nitrogen and the auroral spectrum. L. VEGARD. *Nature* **115**, 837-8(1925); cf. *C. A.* **19**, 609.—V. doubts the validity of McLennan's assumption (*C. A.* **19**, 1097) that each of the 3 maxima of N_1 is to be regarded as a spectral line with a definite wave length. The maxima are moving and the band N_1 approaches the auroral line by diminution of the size of the particles.

FLORENCE N. SCHOTT

Application of fluorescence to chemistry, pharmacy and biology. RENÉ FABRE. *Bull. soc. pharm. Bordeaux* **63**, 178-99(1925).—A no. of org. substances, principally phenol derivs. and alkaloids, have been examd. with respect to their fluorescent properties. The substance was placed on an inclined stage and subjected to ultra-violet radiation filtered through a Wood's screen. The burner was enclosed in an Al envelope and the rays were focused on the substance by an optical system. In order to insure a const. intensity of light there was attached to the binding post of the lamp a watt-meter which registered 240 w. The source of comparison was standardized with respect to the white surface diffusing sunlight. It consisted of a half-watt lamp in the circuit of which was placed a voltmeter and a rheostat. This was regulated to read under 6 v. each time.

A. G. DuMEZ

Possible loss of combined nitrogen in the higher regions of the atmosphere. CAMILLE MATIGNON. *Chimie et industrie Special No.*, 328-30(Sept. 1925).—From a discussion of the results of various observers on the presence of NH_3 in the atm., M. concludes that there is a possibility of part of it reaching the stratosphere and being there decomposed into N and H by the action of ultra-violet light.

A. PAPINEAU-COUTURE

Photochemical studies. V. Certain actinoscopic reactions. A. REYCHLER. *Bull. soc. chim. Belg.* **34**, 236-41(1925); cf. *C. A.* **19**, 2304.—Solns. contg. 0.125 g. KI, 0.5 g. $\text{K}_2\text{Cr}_2\text{O}_7$, and 0.01 g. eosin per 100 cc. show no liberation of I after 3 hrs. in the dark; in weak diffused light after 40 min. the I formed was equiv. to 2.8 cc. of 1% $\text{Na}_2\text{S}_2\text{O}_3$ soln.; after 2 and 10 min., resp., in sunlight the amt. of 1% $\text{Na}_2\text{S}_2\text{O}_3$ used was 6.3 and 16.4 cc. Without either eosin or $\text{K}_2\text{Cr}_2\text{O}_7$ the mixt. forms no I in 40 min. in weak diffused light. The reaction offers a possible standard method for the detn. of actinic intensities, and its study from that standpoint is being continued.

WM. B. PLUMMER

A relation between the velocity of photochemical reactions and the dielectric constant. CHR. WINTHER. *Trans. Faraday Soc.* **1925** (advance proof).—Photochem. reaction velocity generally decreases with increasing dielectric const. This is a generalization from data on the reactions of CHI_3 oxidation and anthracene polymerization. (*Ct. C. A.* **5**, 822, 3367; Luther and Weigert, *Z. physik. Chem.* **53**, 393.)

D. S. V.

Photochemical sensitization. A. BERTHOUD. *Trans. Faraday Soc.* **1925** (advance proof).—A discussion of the different theories of photochem. sensitization.

D. S. V.

The role of water in the photosynthesis of hydrogen chloride. R. G. W. NORRISH. *Trans. Faraday Soc.* **1925** (advance proof).—N. criticizes the mechanism proposed by Coehn and Tramm to account for their exptl. results (*C. A.* **17**, 1591; **18**, 3144) on the photochem. yield of HCl as a function of the pressure of H_2O vapor. Furthermore, Cathala's interpretation of these data (*C. A.* **19**, 2915) is deemed inadequate, since the

postulated Cl atom should have a mean life of 8 sec., in contradiction to the exptl. value of 1/1000 sec. given by Bodenstein and Taylor (*C. A.* 10, 3012). Wherefore, N. has derived a new theory of the reaction, based on the assumption that the primary photochem. change $\text{Cl}_2 + h\nu \longrightarrow 2 \text{Cl}$ occurs on the vessel wall. A surface of 300 cm.^2 is completely covered with a monomol. layer of H_2O mols. when the H_2O pressure is 10^{-6} mm. If H_2O coöperates with light in the atomization of Cl_2 in some such fashion

as the equation $\text{H}_2\text{O} + \text{Cl}_2 \longrightarrow \text{H}_2\text{O} \begin{array}{c} \text{Cl} \\ \diagup \quad \diagdown \\ \text{Cl} \end{array} \longrightarrow \text{H}_2\text{O} + 2\text{Cl}$ would indicate, the cata-

lytic effect should reach a max. when the surface is completely satd. The curve obtained with the aid of this hypothesis bears a formal resemblance to the observations of C. and T. The action of NH_3 and other inhibitors is attributed to preferential absorption on this H_2O layer, and the induction period is predicted quant. This new theory does not dispense with reaction chains as such, to account for the multiple transformation elicited by a single quantum, but limits their performance to the bulk of the gas.

HOWARD R. MOORE

Photosensitivity and the mechanism of chemical reaction. H. S. TAYLOR. *Trans. Faraday Soc.* 1925 (advance proof); cf. *C. A.* 19, 3418.—The Cario and Franck effect (dissociation of H_2 mols. by collisions of the second kind with excited Hg atoms (cf. *C. A.* 17, 489; 18, 2288) is extended to a study of the hydrogenation of C_2H_4 , O_2 , CO , N_2O , CO_2 and N_2 at 0.5–1.0 atm. and at room temp. Reaction velocities estd. by decreases in pressure in the system were 30, 25, and 75 mm./hr., resp., for the first 3 reactions, in contrast to the low value of 0.05 mm./hr. obtained by C. and F. The yields obtained in these expts. are 250 to 30,000 times those formerly obtained at relatively low pressures. Thermal data are utilized in formulating probable chain mechanisms to account for the results. No reduction was obtained for NH_3 and CO_2 , but no great precautions were taken to procure pure and dry gases. The light has no effect on the C_2H_4 , CO and O_2 mols. alone, and hence simultaneous excitation of both participants is unnecessary. In the reduction of CO , HClO , together with CH_4 and polymerized hydro carbons, is formed to a considerable extent, the first instance of the photochem. synthesis of formaldehyde by collisions of the second kind. H. R. MOORE

The fundamental laws of photochemistry. IVAN PLOTNIKOV. *Trans. Faraday Soc.* 1925 (advance proof).—The Grotthus van't Hoff law $v = kA$, connecting the velocity of a photochem. reaction with the absorbed light energy, is a starting point in the formulation of the desired law. The use of this law will be enhanced by inclusion of a mechanism of quantum absorption and the functional dependence of reaction velocity on wave length. Einstein's law has no significance when the photochem. effect is expressed as a function of incident light intensities and chem. mass rather than absorbed energy.

H. R. MOORE

Some conclusions from recent work on photochemistry. D. L. CHAPMAN. *Trans. Faraday Soc.* 1925 (advance proof).—A preliminary communication of results obtained in collaboration with E. Walters on the photochem. HCl reaction. The true induction period corresponding to the mean life of a chain of active mols. is 1/40 sec., and the lower limit of the mean life of Cl_2 is 1/50 sec., in approx. agreement with Weigert and Kellermann (*C. A.* 17, 687). Light intensities were controlled with sector wheels furnishing intermittent illumination, in the manner described by Berthoud and Bellenot (*C. A.* 18, 1786). Precautions were taken to eliminate O_2 , H_2O and N_2 , which act either as positive or negative catalysts. The rate of HCl formation is proportional to the square root of the light intensity, and with small amts. of O_2 is very nearly proportional to the intensity. Einstein's law holds, therefore, under certain specified conditions. The present work does not contradict previous studies of the Chapmans on the influence of light intensity and the kinetics of the reaction (*C. A.* 18, 788, 3323), but necessitates a revision of the various chain mechanisms proposed to account for photochem. yield. Nernst's theory is invalid if the reaction is catalyzed by H_2O , since no provision is made for the occurrence of intermediate compds.; furthermore, the postulated H atoms cannot survive in an atm. devoid of moisture.

H. R. M.

The mechanism of photochemical reactions. N. R. DHAR AND B. K. MUKERJI. *Trans. Faraday Soc.* 1925 (advance proof).—A review of the field, with some attempt at unification of the various phenomena. The primary photochem. effect consists in the activation of mols. by light absorption, a process for which Einstein's law is valid. The subsequent course of the reaction is influenced by heat energy evolved and the phase condition of the reactants, and is not predicable with present knowledge. Hypotheses are advanced concerning the energy of the chem. active state, and the duration of excitation of active species for thermal and photochem. reactions in dil. sols. (cf.

C. A. 19, 3222). Collisions of the second kind explain photosensitization satisfactorily, but photo-inhibition is intrinsically more complex and demands special explanations. The inhibitors described by Anderson and Taylor (C. A. 17, 2676) prevent the direct action of ultra-violet light by forming a protective layer around the reacting H_2O_2 mols. Electron emission during the course of reaction (cf. O. W. Richardson, C. A. 16, 1703) explains the inhibiting powers of traces of substances in photochem. reactions, as well as the high quantum efficiency observed for the HCl synthesis. Thermal and photochem. reactions are not essentially disparate phenomena (cf. D. C. A. 12, 111; 15, 2028; 18, 3520). Photochem. reactions need not possess a temp. coeff. of exactly 1.0. This condition holds only when light activates most of the mols. and when no marked increase of activation is obtained with an increase of temp. H. R. M.

Confirmation of the Einstein law of the photochemical equivalent in a very simple photochemical reaction. FRITZ WEIGERT AND LOTTE BRODMANN. *Trans. Faraday Soc.* 1925 (advance proof).—The reaction selected for test was the photochem. conversion of *o*-nitrobenzaldehyde into *o*-nitrosobenzoic acid, previously investigated by Ciamician and Silber (Ber. 35, 3040) and W. and Kummerer (C. A. 7, 2565). Theoretically, the transformation of isomeric substances (cf. Warburg, C. A. 14, 1931) should fulfil the condition that the law $Q = Nh\nu$ be restricted to primary photochem. processes. Various enviroing factors, such as chem., elec., and kinetic changes, modify the result of the initial light absorption in such a way that the end product of most photochem. reactions is not a satisfactory measure of the primary process. In the present case, however, the entire change is localized within the reacting mol. and secondary processes are practically negligible. The radiation incident on acetone solus. of the aldehyde was measured with a surface bolometer standardized against a Hefner candle, and the absorbed energy calcd. from data given by Hyman (*Dissertation*, Leipzig 1924) for λ 's 436, 405 and 366 μ . The photolec. method of v. Halban and Siedentopf (C. A. 16, 2078) was used to measure the extinction coeffs. Cond. measurements afforded a direct means of estg. the yield of *o*-nitrosobenzoic acid. Einstein's law is very nearly valid, since the "efficiency ratio," $\phi/p = 1/2$, (quotient of the "effective" and "indicated" photochem. equivalents) corresponds to $2 h\nu$ per molecule transformed. The primary cause of the mol. rearrangement is assumed to be the transference of a photoelectron from the CHO to the NO_2 group. Polarized light should exert a sp. influence, since the most favorable condition for transformation occurs only when the elec. vector of the incident radiation harmonizes with the connecting direction of CHO and NO_2 groups. H. R. MOORE

The dissociation theory and photochemical thresholds. E. J. BOWEN. *Trans. Faraday Soc.* 1925 (advance proof).—Observations on the mechanism of photochem. action indicate that the primary process is the formation of an excited mol., and that dissociated fragments or monat. forms such as H, O, N are nonexistent. Nevertheless, the excited-mol. theory fails to account for the close identity between thermochem. heats of linking (heats of dissociation) and the energy increments calcd. from the lower limits of absorption bands. B. has tabulated the heats of linking of C-H, C-C, C-I, Cl-Cl, Br-Br, I-I bonds and compared them with the energies of absorption bands for compds. contg. these linkages. The good agreement obtained for the halogens suggests that these monat. forms are really active in photochem. change (cf. Bowen, C. A. 18, 3548). In most cases, however, the energies of electronic activation, corresponding to the absorption bands, were very much greater than the dissociation energies. Heats of linking represent the difference between the energy of lowest electronic orbits in free atoms and in the mols. The work on band spectra (Mecke, C. A. 17, 2994) does not indicate that electronic activation is accompanied by dissociation. Therefore, for photochem. reactions at least, absorption spectra and heats of linking are not directly related. This conclusion is borne out further by work on bi-mol. thermal reactions (decompn. of HI, N_2O , Cl_2O and the synthesis of HI from the elements). It appears impossible to associate thermal and photochem. activation energies since equiv. energy increments do not produce equiv. chem. effects. Photochem. thresholds are more apparent than real. H. R. MOORE

The radiation theory of chemical reactions. JAMES RICE. *Trans. Faraday Soc.* 1925 (advance proof).—The restricted radiation theory and collision theories alike are deficient in accounting for the velocity of a typical chem. change, such as the monomol. decompn. of N_2O_5 . The rate of activation is 10^{-6} of the exptl. value when the energy absorption is calcd. from Planck's expression for energy distribution, and 10^{-3} too small according to the collision hypothesis advocated by Thomson (C. A. 17, 3823). Lewis and Smith (C. A. 19, 3196) have shown that the radiation theory is adequate when energy absorption is active over a wide range of frequencies, and R. regards this

more probable than the effort of Christiansen and Kramers (*C. A.* 17, 2985) to retain the autonomy of collisions as the sole factor in chem. reactivity by postulating return of the energy of collisions to the mass of unchanged molecules. In this paper R. shows that the chem. data on the decompn. of N_2O_5 are satisfied entirely by the radiation theory, with the supposition that the exchange of energy between matter and light is perpetrated by an oscillator mechanism, similar to the elec. oscillator of Rayleigh (*Science Abstracts* 19A, 1141). Planck's assumption that light absorption is essentially a quantum phenomenon need not be made, since the correspondence principle is not in conflict with at. stationary states. Expressions are derived on classical grounds for the rate of energy absorption at the max., and for indices of refraction and absorption. The treatment is almost entirely mathematical.

H. R. MOORE

Note on the influence of radiation on chemical reactions. L. S. ORNSTEIN. *Trans. Faraday Soc.* 1925 (advance proof).—Lewis (*C. A.* 14, 892) has pointed out that observed temp. coeffs. of monomol. reaction, as well as the sp. reaction velocity const., are not predicted with any degree of accuracy from the radiation theory. When $h\nu$ has a radius of the order of a wave length of light, the calcd. reaction const., is approx. 10^{-10} of the observed value. However, with the use of Franck's view (*C. A.* 19, 435) that primary photochem. processes involve the formation of excited mols., and that the loss of energy is detected by the phenomena of chemi-luminescence or transference of this activation energy to other mols. in the immediate vicinity, O. has developed a mechanism leading to satisfactory values of k_0 . The validity of the equations developed is contingent on the assumption that the various stages in Franck's process are thermodynamically reversible. Calcs. are made only for the N_2O_5 decompn. (cf. preceding abstract).

H. R. MOORE

Absorption of light by solutions of electrolytes. H. VON HALBAN. *Trans. Faraday Soc.* 1925 (advance proof).—This presents the work of Halban and Ebert (cf. *C. A.* 19, 1536).

D. S. VILLARS

Photochemical reactions and methods of measuring them. IVAN PLOTNIKOV. *Trans. Faraday Soc.* 1925 (advance proof).—An address on the difficulties and complications met with in photochem. investigations.

D. S. VILLARS

The relation between quantum sensitivity and intensity of radiation. CHR. WINTNER. *Trans. Faraday Soc.* 1925 (advance proof).—The quantum sensitivity of a reaction (the factor expressing the efficiency of radiation in provoking photochem. change), is not necessarily a direct function of the amt. of energy absorbed. Thus for the deoxygenation process Warburg (*C. A.* 8, 613) has shown that the quantum sensitivity reaches the max. of 4.7 for an energy absorption of 102 (given in arbitrary units). For an energy absorption of 253, the sensitivity is 3.1. Other instances of this disparity of photochem. yield and radiation absorbed are cited. In particular, the oxidation of HI in aq. soln. studied by W. (*C. A.* 18, 1434) gives an approx. linear increase of sensitivity with progressively decreasing absorptions. The fundamental reaction involved is the oxidation of I^- by I_3^- , and it would appear that those I_3^- ions receiving 2–3 $h\nu$ are inactive in starting the process. When each I_3^- is activated by the absorption of 1 $h\nu$, max. velocity is obtained and this condition is realized with feeble intensities.

H. R. MOORE

Einstein's law of the photochemical equivalent. N. R. DHAR AND B. K. MUKERJI. *Trans. Faraday Soc.* 1925 (advance proof).—A list is given of the more important photochem. reactions with yields in mols. transformed per quantum absorbed. The reactions fall into 3 groups; namely, those showing close conformity to the $Q = Nh\nu$ law, and those with positive and negative deviations. The heat liberated in exothermic reactions is a very probable source of the large yields. If electrons or ions are emitted in the course of transformation, they should, in general, supplement the light as a source of activation. This hypothesis seems unlikely since the electrons, if liberated at speeds corresponding to thermal agitation, do not possess enough energy to activate the various mol. species. Furthermore, there is no justification for ignoring this mechanism for endothermal reactions which usually obey the law within exptl. error. Low quantum efficiencies are due to the reversion of active mols. to the normal state before transference of their excitation energy to neighboring mols.

H. R. MOORE

Elementary processes of photochemical reactions. J. FRANCK. *Trans. Faraday Soc.* 1925 (advance proof).—Photochem. changes involve preliminary excitation of the mols. and almost instantaneous conversion of this activation energy into chem. energy by collisions of the second kind or re-radiation of the energy as fluorescence. Under certain conditions this activation energy contributes to the rotation and oscillation values of a diatomic mol., as well as to the electronic system. F. seeks to define these conditions on Warburg's theory (*C. A.* 19, 435) that dissociation can be accomplished

by one elementary act of light absorption. Illustrations are given for various heteropolar and homopolar mols., and 3 general cases are noted: (1) the potential energy between the 2 atoms is decreased by a large change in oscillation energy on light absorption, (2) no change occurs in the potential energy and the oscillation quantum no. is small, (3) excitation of the electronic system is procured at the expense of a decrease in the value of the oscillation quantum no. With heteropolar mols., light absorption results in the formation of a positively charged ion, an electron and a neutral atom; for homopolar mols., resolution into 1 normal and 1 excited atom. The disruption of homopolar mols. is assumed to take place adiabatically (cf. Debye *C. A.* 15, 2226). Absorption of light by the halogens corresponding to their convergent band limits, namely λ 's 5000, 5200, 4800 Å. U. for I_2 , Br_2 and Cl_2 gives excited halogen atoms of energy 1.0, 0.5 and 0.3 v., resp. These values correspond roughly with the energy differences between the normal $2p_2$ and metastable $2p_1$ states of the halogen atoms.

H. R. MOORE

The Einstein "photochemical equivalent law." A. J. ALLMAND. *Trans. Faraday Soc.* 1925 (advance proof).—A re-examines the postulates and implications of Einstein's thermodynamic proof of the quantum equivalence law (*C. A.* 7, 1654). An extensive list of photochem. reactions and data are given. Quantum efficiencies are tabulated according to Warburg's nomenclature. Thus the values of γ in the relation $\gamma = \phi/p$ give an exptl. basis for estg. the degree of departure from theory. (p is the fundamental photochem. equivalent given by $\lambda/28470$, and denotes the no. of mols. decomposed per g. cal. of radiation absorbed; ϕ is the Einstein value.) The Einstein law states that equal chem. effects are produced for equal amts. of energy absorbed; i. e., $Q = nNh\nu = n'N'h\nu'$, where $n' > n$ and $\nu' < \nu$. However, photochem. yields are known to be a function of wave length and gas pressure, and hence the modified Warburg expression $p = (\lambda/28470) \cdot f(\lambda, P)$ is proposed. Since the secondary processes are rarely stoichiometrically equiv. to the primary (represented by higher Bohr states in the reactants), further limitations are introduced. For strict conformity to this ideal law, reactivity should be independent of temp. for a given radiation d. In general ϵ is not equal to $h\nu$, for the mean energy absorption per mol. is a function of temp. A rise of temp. produces smaller values of ϵ and higher γ 's. These deviations are probably inherent in the statistical nature of the law.

H. R. MOORE

Transformation of atoms into radiation. OTTO STERN. *Trans. Faraday Soc.* 1925 (advance proof).—Matter and energy are interconvertible. S. is interested in the transformation of radiation into matter, as well as the inverse process which accounts for the loss of wt. of stars. Thermodynamics is applicable since the calcs. are made for the equil. state. A temp. of 10^9 degrees is equiv. to an electron d. of 1 per cm^4

H. R. MOORE

A suggested mechanism for the ozone-chlorine reaction. A. J. ALLMAND. *Trans. Faraday Soc.* 1925 (advance proof).—The photosensitization of O_3 by Cl_2 is a reaction of zero order; i. e., it is independent of the concn. of O_3 deoxygenized (cf. Weigert, *Ann. Physik* 24, 243; Bonhoeffer, *C. A.* 17, 2392). A. has presented a series of equations for the kinetics of the reaction to account for this fact. The occurrence of active O_2 is a necessary stage in the mechanism, and this assumption is substantiated by the work of Norrish and Rideal (*C. A.* 19, 2301) on the photosensitive formation of H_2O in the presence of Cl_2 . O_3 is transformed to O_2 by collision with active O_2 mols. as well as with Cl_2 mols., as evinced by the reactions (1) $Cl_2 + h\nu \rightarrow Cl_2^*$, (2) $Cl_2^* + O_3 \rightarrow O_2 + \text{energy}$, (3) $Cl_2 + O_2 \rightarrow O_3$, (4) $O_2^* + O_3 \rightarrow O_2 + \text{energy}$. It

is essential in this theory that the life of Cl_2^* and O_2^* is long in comparison to the time taken by such a mol. to encounter an O_3 or O_2 mol.

H. R. MOORE

The law of photochemical equivalents and the place of the quantum theory in relation to the atomic theory and energetics. DANIEL BERTHELOT. *Trans. Faraday Soc.* 1925 (advance proof); cf. *C. A.* 5, 1705, 2024; 9, 1873.—The various forms of energy, such as thermal, elec., and radiant, are given by the product of 2 factors, the tension and capacity factors. Temp., e. m. f. and frequency are the tension factors in the above series; thermal entropy, quantity of electricity and radiant entropy the capacity factors. It follows from the principle of conservation of energy that equal quantities of these energies impart the same velocity to an electron; i. e., the relation $1/2 m v^2 = eE = sT = h\nu$ is valid. The constns. e , s , h , are the so-called invariants of capacity, the "electron," "thermon," and "radion," resp. Furthermore, a chem. reaction should serve as an index of the amt. of energy imparted to the mols., and from the doctrine

of the equivalence of energies the yield should be independent of the nature of the "activating" energy. In testing the photochem. equivalence law, irreversible and trigger actions should be excluded; moreover the photochem. potential (frequency) should be independent of temp. These predictions are verified qual. by a study of the parallelism in the tension factors producing decompn. of the H halides. HI dissociate at red glow; HBr at 700°; HCl at 1500°. The e. m. f.'s of electrolysis for the series increase in the order 0.5, 1.0, 1.4 v., and the effective photolytic frequencies are in the neighborhood of 0.4, 0.3 and 0.2 μ , resp.

H. R. MOORE

Electron affinity of the halogens. E. B. LUDLAM. *Trans. Faraday Soc.* 1925 (advance proof).—The 3 halogens show 2 continuous bands displaced to longer wave lengths with increased at wt; thus for Cl₂, Br₂ and I₂ the wave lengths of the first series are 320, 370, 430 μ , and for the second series 265, 295, 345 μ . The general theories of electron affinity are discussed (cf. Steubing *C. A.* 15, 2790; Franck, *C. A.* 16, 872; v. Angerer *C. A.* 17, 489), and it is concluded that the more ultra-violet bands do not represent a true electron affinity spectrum. Oldenburg (*C. A.* 18, 19; 19, 1988) has referred the origin of these bands for the case of I₂ to the recombination of positive and negative I ions.

H. R. MOORE

Flame spectra and chemical reactions. (MISS) C. E. BLUKER. *Trans. Faraday Soc.* 1925 (advance proof); cf. *Z. Physik* 27, 195(1924). The total intensity of each line emitted in flame spectra is composed of two parts, one due to thermal excitation and the other to energy gained from an oxidation process. For the lines of the subordinate series, the oxidation process prevails, and this can explain why the ratio of the intensities of these lines does not depend on the temp. of the flame. The lines of the principal series are due mainly to temp. excitation and possess the intensities indicated by Planck's law. The intensity for an emission in the subordinate series characterized by a change τ of the total quantum no., n , is given by $T\alpha Be^{-E/k\theta} (\tau 2n/n)^4$ where θ is a fictive temp. detd. from $10 - \log$ heat of reaction; k is the Boltzmann const. and ν is the frequency of the end term.

D. S. VILLARS

Photolysis of methylene blue, sensitized by zinc oxide. EMIL BAUR. *Trans. Faraday Soc.* 1925 (advance proof). The concept that photolysis is a mol. electrolysis is illustrated for the photolyses of acetic acid sensitized by uranyl ion, and AgNO₃ and methylene blue sensitized by ZnO. A phototrope is the isomer of a mol. after it has absorbed a quantum.

D. S. VILLARS

Physical antecedents of the photoactivity of chlorine. WILFRID TAYLOR. *Trans. Faraday Soc.* 1925 (advance proof).—T. observed no change in refractive index of Cl₂ due to activation of the mols. by light of wave lengths shorter than 4990 Å. U. Conclusion: the equil. fraction of activated mols $f = \alpha I/N\psi\beta$ is very small. (α is coeff. of selective absorption; I , the light energy crossing unit area in unit time; N , the no. of original mols; ψ the no. of collisions per unit time due to thermal agitation; and β the probability that deactivation will result from a thermal collision.) A change of the index of refraction of 4.5×10^{-8} was detectable by an interferometer method.

D. S. VILLARS

Formation of polar compounds by photochemical reactions. W. A. NOYES, JR. *Trans. Faraday Soc.* 1925 (advance proof).—The conclusions derived from results of previous work (cf. *C. A.* 18, 2288) on the acceleration of the reaction between Hg and NO₂ by light of wave lengths shorter than the photoelec. threshold of Hg are revised. The light produces an electron d. in the gas. An electron combines with NO₂ forming NO₂⁻, which combines with Hg and liberates an electron. Approx. 10⁶ mols. are formed for each electron. The velocity of reaction depends on the electron d., which is at a max. at zero potential gradient. A retarding or accelerating p. d. diminishes the electron d. and hence the velocity of reaction.

D. S. VILLARS

Becquerel effect on copper oxide electrodes. W. J. D. VAN DIJCK. *Trans. Faraday Soc.* 1925 (advance proof).—A polarizing current i , is sent through a cell Pt, CuO, N KNO₃, Pb and the p. d. of the CuO electrode with respect to the soln. is measured on the assumption that the 0.1 N calomel electrode is 0.619 v. D. then illuminates the CuO with monochromatic light and observes the change in current Δi which occurs when the p. d. of the electrode is kept the same. There is a min. + p. d. for which Δi is zero. (Cf. Goldman, *C. A.* 9, 14) and this is the same for all wave lengths between 8300 and 4490 Å. Similar results are obtained when the electrolyte used is N Zn(NO₃)₂ and N NaBrO₃. Therefore a photoelec. electron ejection from the CuO cannot explain the action. It is established that CuO is the photoactive substance but it could not be proven whether pure Cu₂O had an action or not. It is suggested that the light decomposes CuO into Cu and O₂, the former reducing the CuO to Cu₂O and the latter causing a true oxidation potential at the electrode.

D. S. VILLARS

Chemiluminescence. H. KAUTSKY. *Trans. Faraday Soc.* **1925** (advance proof).—The chemiluminescent spectrum emitted by either rhodamine B or rhodamine sulfonate adsorbed on colorless oxidation products of $\text{Si}_6\text{O}_5\text{H}_6$ when the latter are oxidized either in solu. by permanganate or dry by O_2 , is the same as the fluorescent spectrum of the adsorption compd. These dyes adsorbed on silicic acid may be oxidized by KMnO_4 but no chemiluminescence appears. The chemiluminescence is explained thus (cf. *C. A.* **16**, 2809; **17**, 2081): these derivs. of Si are built up of lamellae consisting of layers only one or two mols. thick. The energy of the oxidation is easily transferred to the adsorbed mols. which are activated thereby and which luminesce on returning to their normal state.

D. S. VILLARS

4 - ELECTROCHEMISTRY

COLIN G. FINK

An improved form of electric vacuum furnace. J. R. PARTINGTON AND N. L. ANFILOGOFF. *Trans. Faraday Soc.* **1925** (advance proof).—The authors designed an elec. vacuum furnace, similar to the Otto Ruff type but with certain mech. and elec. improvements, for studying reactions at high temps. The reacting substances are placed in a graphite crucible made of the same material as the hot tube and maintainable either in high vacuum or in an atm. of an inert or reacting gas. An historical account of the elec. vacuum furnace is included. The authors' furnace consists of a graphite tube surrounded by a radiation case and enclosed in an air-tight, H_2O -cooled, bronze casing. Construction details relating to the furnace casing, the hot tube, insulation, etc., are thoroughly described with the aid of several drawings.

A. D. SPILLMAN

Induction furnace progress. ANON. *Electrician* **95**, 620(1925).—A brief account is presented of the progress made in the development of the high-frequency furnace during the past 20 years. The investigations of G. Ribaud, which were pursued independently of those of E. F. Northrup, were further carried out by the French Compagnie Électro-Thermique in 1924. In the Northrup method the alternate charge and discharge of the condensers is effected by a stationary spark gap, whereas in the Ribaud system it is rotary. It is claimed that the latter method results in a higher power factor. At the Paris shops of the company 6 kg. of rusty flakes of electrolytic Fe were melted (1600°) in 40 min., of which 5 min. represented the time for the inspection of the charge, with a demand of 10–12 kw. at the start and a current consumption of 80–82 amp. (110 v. supply) at the end of the run.

A. D. SPILLMAN

Haglund process for the electrothermic production of alumina. T. R. HAGLUND. *Ind. Eng. Chem.* **18**, 67 8(1926).—In the H. process the impurities Fe, SiO_2 , etc., in the bauxite are reduced by C (coke or charcoal) in a continuous elec. furnace. Sufficient sulfide material is added, either as Al_2S_3 or pyrotite, to form a slag of Al_2O_3 contg. 15 to 20% of Al_2S_3 . The compn. of the charge is discussed. This slag is very fluid, has a fairly low m. p., and is easily handled. On cooling the Al_2O_3 crystallizes in the slag, the size of the crystals depending on the rate of cooling. A pig Fe contg. very little S, but all of the Si in the charge is also formed. The cold slag of Al oxide-sulfide is crushed, treated with H_2O to hydrolyze the sulfide to hydroxide and evolve H_2S . The dried residue of Al_2O_3 , $\text{Al}(\text{OH})_3$, Fe sulfide, etc., is mechanically sepd. by classifiers, jigs, etc. The impurities in a Swedish or German sample of Al_2O_3 prep'd. by the H. method are as follows: SiO_2 trace to 0.02%; TiO_2 0.18 to 0.26%; S 0.16 to 0.20%; Fe_2O_3 trace to 0.12%. Production costs are tabulated and compared to the Bayer chem. method based on German procedure at Lautawerk.

C. J. BROCKMAN

The electrolytic separation of copper. ROBERT SAXON. *Chem. News* **131**, 225–6 (1925); cf. *C. A.* **19**, 3432. A brief discussion of the deposition of Cu from solns. or suspensions of Cu pyrites, CuSO_4 , or malachite in the presence of NH_4 salts.

C. J. BROCKMAN

Change in concentration of electrolytic impurities. M. DEKAY THOMPSON. *Chem. Met. Eng.* **32**, 700(1925).—An equation is derived which gives the variation in the concn. of an impurity in an electrolyte with time, the amt. of impurity removed and the introduction of impurity being const. for each unit of time. This equation permits the calcn. of the time required to attain the equil. concn. of impurity and it is applied to Ni in Cu refining electrolytes and to the accumulation of impurities in boiler water.

G. DUBERNELL

Apparatus for the electrolytic production of dichromates, persalts, chloroform, etc. I. SHCHERBAKOV. *Z. Elektrochem.* **31**, 360–2(1925).—In the electrolysis of alkali salts, some of the free alkali which accumulates at the cathode diffuses to the anode where

it greatly interferes with anodic yields. To prevent this S. has devised the following app.: A tall beaker is the retaining vessel in which is placed a smaller porous pot contg. Hg, which is the cathode. The surface of the Hg is covered with water to decompose the amalgam as it rises to the surface of the denser Hg. To prevent the diffusion of the NaOH soln. so formed, the Hg surface must be well above the surface of the anolyte which is outside the porous pot. In the anolyte any anode whatsoever may be placed. To produce good circulation of the Hg cathode and rapidly remove the amalgam, pure Hg may be injected into the bottom of the cathode area through a funnel tube to force a more rapid rise of the lighter amalgam which may be drawn off at the top of the porous pot. This app. has been applied with increased efficiency to the prepn. of dichromates, persulfates and CHCl_3 . C. J. BROCKMAN

The microstructure of electrodeposits. ANON. *Metallwaren-Ind. u. Galvano-Tech.* **23**, 443-4, 467-8, 491-2 (1925).—The subject is reviewed. The influence of c. d., temp., movement and bath compn. are discussed and in connection with the latter complex salts, free acid and colloid addns. are taken up. It is concluded that "it follows from all these considerations that very much investigational work is still to be done before the influence of the various factors on the structure of electrodeposits can be held to be entirely explained." G. DUBPERNELL

Defective phenomena in the nickel plating of castings. ANON. *Metallwaren-Ind. u. Galvano-Tech.* **23**, 470-1 (1925).—In Ni plating castings there were sometimes spots where no electrodeposit could be produced and these spots were found to be sulfide segregations in the surface of the casting. Decreasing the sulfide content, castings of thinner cross-section, and more rapid cooling are recommended as means for avoiding this difficulty. G. DUBPERNELL

Rust-resistant nickel plating. ANON. *Metallwaren-Ind. u. Galvano-Tech.* **23**, 605-6 (1925).—Corrosion, Ni, Zn, Cu, etc., plating and the porosity of electrodeposits are discussed with special reference to the electrochemistry involved. Hot galvanizing is recommended as a preliminary to electroplating. It is followed by Cu or brass plating and then Ni plating. A bath of NiSO_4 6.8, MgSO_4 2.4, NH_4Cl 0.8, H_3BO_3 0.32 kg. and water 100 l. is recommended; for barrel plating NiSO_4 11, MgSO_4 8, NH_4Cl 0.2, $(\text{NH}_4)_2\text{SO}_4$ 2 kg. and water 100 l. are recommended. G. DUBPERNELL

Deposition of metals upon stainless steel. J. HAAS AND E. R. UNRUH. *Metal Ind. (N. Y.)* **23**, 451-2; *Metal Ind. (London)* **27**, 533-4 (1925).—Considerable difficulty is encountered if the deposition of other metals upon stainless steel is attempted for any reason. The deposits are usually badly blistered and nonadherent. Of all of the methods tried in prep., the surface for deposition a concd. HCl soln. at 60° with the object as cathode gave the best results. In using immersion dips, it was noticed that an evolution of gas was produced after a few sec. immersion. Gas evolution was most vigorous in the 20% H_2SO_4 soln. at 60° , and this dip gave the best results for immersion methods. It seemed to be necessary to destroy the surface passivity and then plate the object immediately to obtain an adhesive deposit. G. DUBPERNELL

Principles and operating conditions of chromium plating. H. E. HARING. *Chem. Met. Eng.* **32**, 692-4, 756-7; *Bur. of Standards, Letter Circular* 177; *Brass World* **21**, 395-6; *Metal Ind. (London)* **27**, 310-2 (1925); *Mon. Rev. Am. Electroplaters Soc.* **12**, (Oct., 1925).—Scratch hardness measurements recently made at the Bur. of Standards on deposits of Cr indicate that it is considerably harder than the hardest steel. In the Cr plating of printing plates a bath consisting of 250 g./l. (33 oz./gal.) of CrO_3 , 3 g./l. (0.4 oz./gal.) of $\text{Cr}_2(\text{SO}_4)_3$, 7 g./l. (1 oz./gal.) of $\text{Cr}_2\text{O}(\text{CO}_3)_2$ was used at a temp. of 40 – 50° and c. ds. 100 to 200 amp./sq. ft. (11 to 22 amp./sq. dm.). Deposits of about 0.0002 in. (0.005 mm.) of Cr were obtained under these conditions in 30–60 min. with the metal efficiency at approx. 12%. The voltage was about 7 to 9 v. Methods of analysis are outlined. The metal efficiency and the character of the deposit tend to vary erratically and H. postulates the necessity of the presence of an excess of colloidal "chromium chromate" to maintain a const. pH . The poor throwing power due to decreasing cathode efficiencies with decreasing c. ds. must be improved if Cr plating is to be utilized on recessed work. Because of passivity, work to be plated must be introduced into the bath with the current flowing. G. DUBPERNELL

Overcoming plating troubles. H. C. BERNARD. *Abrasive Ind.* **6**, 380-1 (1925).—

mixing in addition, the soln. should be allowed to stand before using as the sediment will settle on the work, causing pit marks. Another cause of pitted deposits is insufficient metal in the soln. To remedy this about

2 oz./gal. (15 g./l.) of NiSO_4 is added. A very dark rough deposit indicates too high current or "burning." If the deposit is easily cut through when buffed, not enough current was used in plating. If a CuCN bath contains too much CN and a strong current is used, a blistered or peeled deposit will result; CuCO_3 is added to remedy this. With insufficient cyanide the anodes become coated and the deposit shows a dark muddy appearance. A rough granular Cu deposit is the result of too much current. A few ounces of Na hyposulfite to each 100 gal. will brighten the deposit to a great extent. Temp. of baths, anode area and preliminary cleaning are all important factors. A muddy, streaky deposit from a brass soln. shows insufficient cyanide. A reddish shade of the deposit indicates the addn. of ZnCO_3 or $\text{Zn}(\text{CN})_2$ or NH_4OH . A pink deposit denotes too much Zn or not enough Cu in the soln. A dull grayish deposit indicates too much cyanide or too much current. Addns. to brass baths should be small and very carefully made. Ag solns. generally give very little trouble. AgCl or AgCN together with NaCN or KCN is occasionally needed to replenish them. Too much current gives a burned deposit of a dark brownish appearance. Cleaning the work well before plating is very important. Operating conditions of the Ni , Cu , brass and Ag baths are given.

Electrolytic deposition and refining of metals. E. DUHME. U. S. 1,567,791, Dec. 29. An auxiliary cathode is placed nearer the anode than the main cathode and the

auxiliary cathode is supplied with a suitable current so that it takes up most of the impurities while pure metal is deposited on the main cathode.

Electrolytic production of continuous metal sheets. J. PORZEL. U. S. 1,567,079, Dec. 29. Mech. features.

Electrodeposition of other metals on tungsten. A. S. CACHEMAILLE. Brit. 233,470, Feb. 27, 1924. W or other material is coated with a mixt. of Th and another metal such as Pb, Fe, Ni or Cu by electrodeposition from a soln. of salts of the metals contg. lactate or other org. acid radical or fluoborate, fluosilicate or the like. Details are given for coating filaments, electrodes, X-ray targets, etc.

Metallic magnesium. P. COTTRINGER and S. B. HEATH. U. S. 1,567,318, Dec. 29. A molten bath contg. $MgCl_2$ is electrolyzed and $MgCl_2$ is added to the bath adjacent the anode.

Electrothermic production of zinc. NORSK HANDELS- OG INDUSTRIELABORATORIUM A.-S. Norw. 37,835, June 29, 1925. The process is carried out in rotary, oscillatory or otherwise moved furnaces. The residues from the treated charge are removed by automatic opening and closing the space in which the residues are accumulated, this space being itself in const. motion like the furnace.

Electrothermic production of zinc. NORSK HANDELS- OG INDUSTRIELABORATORIUM A.-S. Norw. 40,212, June 29, 1925, cf. preceding abstract. The liquid Zn is removed by automatic opening and closing of the space in which it is accumulated during the process, this space being itself in const. motion like the furnace.

Condensing electrothermally produced zinc. NORSK HANDELS- OG INDUSTRIELABORATORIUM A.-S. Norw. 41,408, June 2, 1925. The condensation channels, or the connection channels between the furnace and the condenser are built in an upwardly inclined direction and are provided with a "pocket" for accumulating the condensed products.

Manufacture of ferro-chromium and other ferro-alloys. D. W. BERLIN. Swed. 59,240, Aug. 5, 1925. The raw materials are introduced in an elec. furnace in the form of electrodes in contact with the metal bath which is covered by a layer of slag. The metals are reduced as the electrodes are smelted down successively by the elec. produced heat.

Apparatus for electrolytic manufacture of copper sheets. M. A. JULLIEN. U. S. 1,567,737, Dec. 29.

Rectifying alternating current. H. G. ANDRE. Brit. 233,292, April 30, 1924. The container of a rectifier is made of Pb contg. Sb to which a Ni electrode is fixed. A Ag electrode is sepd. from the container by a glass tube and contains colloidal Ag which is in contact with the Ni electrode. Graphite may be used instead of Ag, and Si, Pb contg. Sb or other suitable materials may replace the Ni electrode.

Protecting boilers, evaporators or other metal surfaces from encrustation by use of an electric current. G. C. FREEMAN. U. S. 1,568,728, Jan. 5.

Electroplating with nickel and copper. F. M. BAKER. Brit. 233,161, May 26, 1924. Steel plates of vehicle springs or other articles are coated first with Ni, then with Cu and finally with another coat of Ni; high c. d. is used in each plating operation. Details of electrolyte compn., etc., are given.

Electroplating with zinc, copper and other metals. BRITISH THOMSON-HOUSTON CO., LTD. Brit. 233,354, May 2, 1924. Compact and brilliant deposits are obtained by adding to the usual electrolyte either Cr sulfate or chrome alum, preferably in their green modifications. Gelose also may be used.

Electroplating iron. H. HARBECK and A. LANGLER. Swed. 58,893, June 10, 1925. A thin coat of a more electropositive metal, for instance Zn or Cd, is first applied to the iron and then the final coating of a more electronegative metal is applied.

Electric ozone generator. F. MAGRINI. Brit. 233,418, Feb. 6, 1924.

Filaments for incandescent lamps. GENERAL ELECTRIC CO., LTD. Brit. 233,294, May 3, 1924. Cryst. oxides or other substances besides metals are encased in or mixed with metals such as Cu, Ni or Fe while worked and the protecting metal is removed after the working. Refractory oxides such as thoria may be encased in a tube of W. Heat treatment to increase the size of the crystals is also described.

5—PHOTOGRAPHY

C. E. K. MEES

Dye chemistry and photochemistry. II. ŚEĐLACZEK. *Phot. Ind.* 1925, 978-9.—The properties of basic dyes in relation to their use for dye toning pictures are discussed. The formation of lakes, the adsorption of the dye by mordants, and the effect of tanning the gelatin in the picture area are explained. The relation of certain reactions to working processes is shown. M. L. DUNDON

Problems of photographic manufacture. II. R. BLOCHMANN. *Phot. Ind.* 1925, 890-1.—The recovery of solvents in raw film manuf. is discussed. One m. of normal motion picture film base weighs about 5 g. and requires about 15 g. of solvent. Acetone, EtOAc and alc.-ether mixs. are commonly used. Freezing out the vapor is satisfactory only with acetone. Liquids used to absorb the vapors are NaHSO₃ soln. (for acetone), H₂SO₄ and cresol. Recently absorbent charcoal has come into use. M. L. DUNDON

Fixing bath and fixing time. I. STRAUSS. *Phot. Ind.* 1925, 881-4.—Various factors which affect the time of fixation were studied. Tests were made with positive film and strips were hung in the soln. but not agitated. Sp. gr. tables checked were incorrect relative to the concn. of Na₂S₂O₃. Most rapid soln. took place in a soln. contg. 25-40% Na₂S₂O₃·5H₂O. NH₄Cl accelerated fixation with a concn. of Na₂S₂O₃·5H₂O below 30%. Fixation was accelerated by NaCl and retarded by NaBr, Na₂SO₄ and MgSO₄. KNO₃ had a max. accelerating effect at 1.2-1.6% but in concn. above 4.8% retarded the action. Na₂SO₃ (crystals) in neutral Na₂S₂O₃ caused turbidity at a concn. of 6% and tended to neutralize an acid bath. II. *Ibid.* 911-6.—Data show the retarding effect of KI and the accelerating effect of NH₄Cl fixation. The influence of several other salts was also tested. In practice a fixing bath is usually discarded long before the theoretical amt. of Ag is in soln. Experience showed that from 1000 m. of raw film 100-105 g. of Ag could be recovered by the sulfide method. The use of regenerated hypo is not advisable. M. L. DUNDON

Latent images produced on photographic plates immersed in water or solutions by making contact with various metals. SEITARŌ SUZUKI AND KŌGORŌ KAWADI. *Nagaoka Anniv. Vol.* 1925, 189-92; *Japn. J. Physics* 4, 12A.—Latent images are formed when the photographic plates in contact with some metallic plates are immersed in H₂O or solns. These images are made strong or weak by passing an elec. current or by increasing the contact pressure. These phenomena have been studied and a probable explanation for the formation of these latent images is offered. C. J. W.

The preparation of so-called "grainless" plates for the interference color process of Lippmann according to Dr. Hans Lehmann. RICHARD JAHR. *Phot. Ind.* 1925, 1013-4.—Complete directions are given for mixing, sensitizing and coating emulsions for the Lippmann process. M. L. DUNDON

Development in bright light. A. HÜBL. *Phot. Rund.* 62, 235-8(1925).—The amt. of desensitizing action on a photographic plate in a given soln. of a desensitizer is proportional to the amt. of liquid taken up by the gelatin. This holds whether the time of bathing or the temp. is varied. Conclusion: the desensitizer is without chem. action on the AgBr, becomes active only when the AgBr is illuminated, and need only to be in intimate contact with the Ag salt in order to decrease its sensitiveness. These conclusions are in agreement with the fact that a plate treated with a desensitizer gains sensitiveness on long washing. H. states that his conclusions are not opposed to Lippman-Cramer's oxidation theory of desensitizers. M. L. SEYMOUR

Development in bright light. The panchromatic plate. A. HÜBL. *Phot. Rund.* 62, 198-200(1925); cf. *C. A.* 19, 2305.—The ratio of the decrease in red and green sensitiveness to the decrease in blue sensitiveness effected by different desensitizers acting on plates sensitized with different dyes is investigated. Sensitizing dyes are divided into 3 classes on the basis of the amt. by which desensitizers reduce their action. The sensitiveness from isocyanines is almost completely destroyed; pinacyanol is more resistant; pinachrome violet and pinachrome blue are still more resistant. The efficiency of the desensitizers was found to be in the following order: pinakryptol yellow, pinakryptol green, phenosafranine, the first being the most powerful. H. recommends for the development of panchromatic plates in yellow light, a prebath in 1:2000 pinakryptol yellow and the addn. of 5 cc. of 1:1000 pinakryptol green for each 100 cc. of developer. M. L. SEYMOUR

Two-color cinematography by metallic toning. ANON. *Brit. J. Phot. Color Sup.* 19, 43-4(1925).—A patent specification granted to the Kelley Color Lab. of New Jersey describes a method of obtaining 2 registered superposed images in the same

sensitive layer. The first positive image is produced by controlled printing from a color negative through the film base on the under side of the emulsion, developing in an amidol developer, toning blue-green in a V toning bath and clearing in a dichromate bromide soln. After drying in the dark or by ruby light the red color image is printed on the emulsion side in the residue of the original sensitive layer. This second image is developed up in the amidol developer, fixed in 60% $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ toned in a U bath and finally fixed in a $\text{Na}_2\text{S}_2\text{O}_3$ - $\text{K}_2\text{S}_2\text{O}_8$ soln. GLENN E. MATTHEWS

Dyes and photochemistry (SEDCLACZEK) 25.

Compensating the copying intensity of cinematographic picture films. E. LEHMANN. U. S. 1,568,511, Jan. 5 The gelatin coating of the film is impregnated with a coloring agent incapable of yielding fast colorations with the film.

Sheets or films for picture projection screens, etc. W. G. MORSE. U. S. 1,568,463, Jan. 5. Finely divided MgCO_3 mixed with linseed oil or other oil is used for making sheets or screens. Varnish, gelatin compns., etc., also may be used.

Preservative for motion picture films. J. I. CRABTREE. U. S. 1,568,658, Jan. 5 Films are treated with a bath contg. H_2O together with glycerol 1-10 and ethylene glycol 10-50% in order to maintain suppleness and prevent undue drying out.

Reproductions for book printing. D. SCHARSCHAWSKY. U. S. 1,567,333, Dec. 29. A developed Ag colloid layer is placed on a platen and treated with a dichromate or other tanning agent to prep. it for etching and use in printing.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

The coördination valence of two hydroxy groups in ortho position. I. Complexes of pyrocatechol and pyrogallol with the acids of the molybdenum group. L. FERNANDES. *Gazz. chim. ital.* **55**, 424-40(1925).—F. (C. A. **18**, 1252) has described 3 series of MoO_4 derivs. of gallic acid. Weinland has prep'd. compds. of pyrocatechol with Fe^{++} , Fe^{+++} , Al, Co and MoO_3 . F. has begun a systematic study of the complexes of this sort. In this paper those of MoO_2 , WO_3 and UO_3 with pyrocatechol (I) and pyrogallol (II) are described. The free acids of these complexes are unstable while the salts are quite stable. These complex acids are mostly weak and with alkali metals or Tl they give acid salts; with org. bases they give disubstituted well-crystd. salts. A series of salts contg. 1 mol. of the phenol and another having 2 mols. for each mol. of MoO_3 was obtained. The first contains 1 mol. H_2O but the 2nd does not. The constitution of the series is represented thus: $\left[\text{XO}_3 \begin{smallmatrix} \text{H}_2\text{O} \\ \text{Ph} \end{smallmatrix} \right]_R$ and $\left[\text{XO}_2 \begin{smallmatrix} \text{Ph} \\ \text{Ph} \end{smallmatrix} \right]_R$ where $\text{XO}_3 = \text{MoO}_3$, WO_3 , UO_3 and $\text{R} = \text{H}$, K, Na, Tl, guanidine, pyridine, etc., Ph = aromatic org. compd. contg. 2 OH groups in the *o*-position to each other. Among the compds. besides I and II that form such colored complexes are hydroxyhydroquinone, 1,2- and 2,3-naphthols, etc., also alizarin, adrenaline, pyrocatecholaldehyde. In compds. having 3 OH groups the 3rd OH does not show a coördination valence. The 1st type of compds. is obtained easily by heating and successive evapn. of solns. contg. stoichiometric amts. of the phenol and inorg. salt. The 2nd type was usually more difficult to prep. In aq. soln. compds. of the 1st type are usually obtained; a large excess of the phenol is required to give II. In EtOH soln. this excess is not required. The mass action effect of the H_2O in this reaction is visualized by the equil.:

The fact that the H_2O is only eliminated from these salts of the 1st type with difficulty indicated that it is probably H_2O of constitution. The salts of I are more stable than those of II. The alkali and NH_4 salts of *pyrogallolalquomolybdic acid* are very sol. and unstable; on evapn. of their aq. solns. sirups that could not be crystd. were obtained. A soln. of guanidine carbonate in MoO_3 gave on evapn. *guanidine molybdate* (III). III in EtOH with the calcd. amt. of II gave a red soln. which on evapn. at 50°

gave *diguandine pyrogallolaquomolybdate*, $\left[\text{MoO}_3 \begin{smallmatrix} \text{C}_6\text{H}_4\text{O}_3 \\ \text{H}_2\text{O} \end{smallmatrix} \right] \text{CNH}_2(\text{NH}_2)_2$ red crystals. If H_2O is used as solvent and some MoO_3 is also added the *guanidine salt* (IV) $\left[\text{MoO}_3 \begin{smallmatrix} \text{C}_6\text{H}_4\text{O}_3 \\ \text{H}_2\text{O} \end{smallmatrix} \right] \text{CNH}_2(\text{NH}_2)_2$, is obtained. An aq. soln. of IV treated with a sol. Tl salt gave a microcryst. ppt. of the corresponding *thallium salt*. On cooling a soln. contg. III and excess of II, *diguandine dipyrogallol molybdate*, $\left[\text{MoO}_2 \begin{smallmatrix} \text{C}_6\text{H}_4\text{O}_3 \\ \text{C}_6\text{H}_4\text{O}_3 \end{smallmatrix} \right] \text{CNH}_2(\text{NH}_2)_2$ dark red to black crystals is sepd. The soln. of this salt with a Tl salt pptd. *thallium dipyrogallolmolybdate*. I acting on NH_4 tungstate in H_2O soln. gave on evapn. *ammonium pyrocatechol aquotungstate* (V), $\left[\text{WO}_4 \begin{smallmatrix} \text{C}_6\text{H}_4\text{O}_2 \\ \text{H}_2\text{O} \end{smallmatrix} \right] \text{NH}_4$, as dark red scales. A soln. of I with K tungstate evapd. at low temps gives the corresponding *potassium salt*. If heated to boiling for a few min an unknown compd. is formed contg. no org. matter. Solns. of V with a sol. Tl salt ppt. the *thallium salt*. If an excess of I is added to the soln. of V it becomes darker and on evapn. a sirup is obtained from which crystals of *ammonium dipyrocatecholtungstate*, $\left[\text{WO}_2 \begin{smallmatrix} \text{C}_6\text{H}_4\text{O}_2 \\ \text{C}_6\text{H}_4\text{O}_2 \end{smallmatrix} \right] \text{NH}_4$, were sepd. *Ammonium pyrogallolaquotungstate* was obtained like V; its soln. with TiNO_3 pptd. the *thallium salt*; the *potassium salt* was also prepd. *Ammonium dipyrogalloltungstate* is very sol. in H_2O and EtOH. The alkali and NH_4 salts of *pyrocatecholaquouranic acid* could not be crystd. Uranyl sulfate uranate with the calcd. amt. of I and then $\text{C}_5\text{H}_5\text{N}$ pptd. *pyridine pyrocatecholaquouranate*, $\left[\text{UO}_3 \begin{smallmatrix} \text{C}_6\text{H}_4\text{O}_2 \\ \text{H}_2\text{O} \end{smallmatrix} \right] \text{C}_5\text{H}_5\text{N}$, as brick-red microcrystals. When a large excess of I is present *pyridine dipyrocatechol uranate*, $\left[\text{UO}_2 \begin{smallmatrix} \text{C}_6\text{H}_4\text{O}_2 \\ \text{C}_6\text{H}_4\text{O}_2 \end{smallmatrix} \right] \text{C}_5\text{H}_5\text{N}$, is pptd. *Ammonium pyrogallolaquouranate*, $\left[\text{UO}_3 \begin{smallmatrix} \text{C}_6\text{H}_4\text{O}_3 \\ \text{H}_2\text{O} \end{smallmatrix} \right] \text{NH}_4$, was obtained; likewise the *pyridine* and *thallium salts*. *Pyridine dipyrogallol uranate* was prepd from uranyl sulfate, excess II and $\text{C}_5\text{H}_5\text{N}$. Also in *Atti accad. Lincei* [6], 1, 439–43 (1925). E. J. WITZEMANN

Reduction of inorganic halides. IV. The reduction of tantalum pentachloride. OTTO RUFF and FRITZ THOMAS. *Z. anorg. allgem. Chem.* 148, 1–18 (1925); cf. C. A. 16, 2456; 17, 2842—Various reduced chlorides are obtained by the method described previously. TaCl_5 reacts with H_2O in evolving the stoichiometrical equiv. of H and dissolves as green Ta oxytrichloride. Pure TaCl_3 solns. are green and stable. Pyrophor chlorides are slowly dissolved by water, quicker by alkali. Ta is formed only above 300° and may thus be sepd. from H_2TaO_4 by alkali. A product TaO_2Cl is obtained by sublimation. V. **Derivatives of tantalum trichloride.** *Ibid* 19–24.—Reply to Lindner and Feit (C. A. 18, 3154). The compd. described by L. and F. as $(\text{HTa}_3\text{Cl}_7\text{H}_2\text{O}) \cdot 3\text{H}_2\text{O}$ (chloroacid of Ta^{++}) is in reality $\text{Ta}_3^{++}\text{Cl}_7\text{O} \cdot 3\text{H}_2\text{O}$ as is shown by detn. of the H evolved by NaOH and control of the method of analysis used by L. and F.

JOHN T. STERN

Molybdovanadates. II. G. CANNERI. *Gazz. chim. ital.* 55, 390–6 (1925).—In a previous paper (C. A. 18, 1620) the importance of temp. in the formation of molybdovanadic compds. was pointed out. Two kinds of crystals were obtained. The red crystals were considered to be a series of mixed crystals; the yellow ones were thought to be definite compds. The limits of existence of both kinds were detd. at 30° . In this paper the limits of existence at 15° were detd. and both kinds of crystals were obtained by the crystn. of solns. of MoO_3 and alkali metavanadates. The red crystals were rich in V, well-formed and sol.; the colorless or yellow ones are rich in Mo, pulverulent and a little sol. The compn. is, in general, in relation with that of the solns. With KVO_3 solns. contg. 1 mol. V_2O_5 + 0.5 mol. MoO_3 red crystals contg. 14.62% MoO_3 were obtained; with 1 mol. each of V_2O_5 and MoO_3 the red crystals contained but 3.57% MoO_3 , while with 1 mol. V_2O_5 to 1.12 mol. MoO_3 they contained 0.34% MoO_3 . At higher ratios of MoO_3 yellow crystals ($4\text{K}_2\text{O} \cdot 0.6\text{MoO}_3 \cdot 3\text{V}_2\text{O}_5 \cdot 10\text{H}_2\text{O}$ and $5\text{K}_2\text{O} \cdot 10\text{MoO}_3 \cdot 4\text{V}_2\text{O}_5 \cdot 14\text{H}_2\text{O}$) rich in Mo were obtained. If it is admitted that in these solns. at least 2 different ionic groupings are present and in equil. with each other, the one belonging to the polyvanadates and the other belonging to a complex radical of the heteropoly type, it is clear that the compn. of the red crystals will not depend so much on the concn. of the compds. added as on that of the ionic groups that are formed from them. The addn. of MoO_3 or raising the temp. changes the equil. in favor of the ionic grouping belonging to the definite (yellow) compds. With the Na and NH_4 salts the change in

compn. of the red crystals is continuous. Red crystals of the Na and K salts ($1V_2O_5 + 0.5 MoO_3 + 1K_2O$ (or Na_2O)) were obtained from different portions of the same solns. Those obtained at 30° contained much more Mo than those sepd. at 15° . These were recrystd. and fractionated and gave $K_4V_6O_{17} \cdot 9H_2O$ and $Na_4V_6O_{17} \cdot 15H_2O$, resp., contg. a trace of Mo. The yellow crystals resist fractionation as long as the temp. remains unchanged. Thus $4(NH_4)_2O \cdot 3V_2O_5 \cdot 5MoO_3 \cdot 10H_2O$ remained unchanged when recrystd. a no. of times at 30° but when crystd. at 10° a different salt, $2(NH_4)_2O \cdot 2V_2O_5 \cdot 5MoO_3 \cdot 10H_2O$, was obtained. This supports the suggestion as to the inherent difference in the nature of the red and yellow crystals. Even the yellow salts show a restricted field of existence. Two NH_4 salts $2(NH_4)_2O \cdot 3MoO_3 \cdot 2V_2O_5 \cdot 8H_2O$ and $4(NH_4)_2O \cdot 6MoO_3 \cdot 2V_2O_5 \cdot 6H_2O$ and 1 Na salt ($2Na_2O \cdot 3MoO_3 \cdot V_2O_5 \cdot 10H_2O$) not described in the previous paper were obtained.

E. J. WITZEMANN

Complex sulfites and thiosulfates of the rare earths. G. CANNERY AND L. FERNANDES. *Gazz. chim. ital.* **55**, 440-53 (1925).— H_2SO_3 in forming complex metallo-sulfurous anions gives rise to 2 series of heteropoly compds.—the uranyl sulfites and the molybdosulfites—the structure of which is known and which are fully reviewed here. C. and F. wished to det. if rare earths can enter into these compds. in place of the alkali metals, although their valences are different. In the same way the substitution of these elements in cuprosulfites and cuprothiosulfites was studied. In the prepn. of the uranyl sulfites the rare earth hydroxides were suspended in the smallest possible quantity of H_2O and SO_2 passed to satn., giving the bisulfite. An aq. suspension of NH_4 pyrouanate was satd. with SO_2 , giving a limpid liquid. The 2 solns. were united and heated moderately at reduced pressure. The complex seps. as a yellow ppt. that was filtered off and washed with $EtOH$ and Et_2O . These salts are insol. in H_2O , $EtOH$ and Et_2O but sol. in dil. acids with the evolution of SO_2 . The product thus obtained failed to give a definite compd. It appeared to be a mixt. from which the constituents could not be sepd. The hydroxide and the pyrouanate were then suspended in H_2O and satd. with SO_2 and enough H_2O was added for complete soln. This was then crystd. by heating on a H_2O -bath in a current of SO_2 . These products resembled the others and had a variable compn. These results show the influence of temp. and pressure on these solns. of uranyl sulfites satd. with SO_2 and the sepn. of addn. products that vary in compn. depending on the SO_2 content and the component in excess. The successful procedure follows: the rare earth bisulfite was prepd. as before and added to an aq. soln. of UO_2SO_4 . The mixt. was allowed to crystallize by slow evapn. *in vacuo* at room temp. The product resembled those obtained before but had a const. compn. $(UO_2)_5 \cdot (SO_3)_3 R_2^{++} \cdot 15H_2O$ ($R = La, Ce, Nd, Pr$) and by analogy with the result of Kohlschütter (*Ann.* **144**, 1 (1900)) may be constituted thus: $O_5S \cdot R \cdot SO_3 \cdot UO_2 \cdot SO_3 \cdot UO_2 \cdot SO_2 \cdot UO_2 \cdot SO_3 \cdot UO_2 \cdot SO_3 \cdot UO_2 \cdot SO_3 \cdot R \cdot SO_3$. The cerium, lanthanum, praseodymium and neodymium uranyl sulfites were prepd. and analyzed. A concd. soln. of NH_4 paramolybdate was satd. with SO_2 and united with a soln. of the rare earth acetate and slowly evapd. *in vacuo*. Three fractions of crystals were obtained. The 1st fractions contained much of the rare earth while the last fraction contained little or none. No fraction obtained showed a compn. corresponding to the pure rare earth molybdosulfite and the series as a whole appeared to be miscible in the solid state with NH_4 molybdosulfite. This is thought to be an instance of *isomorphism of mass* in which the influence of the mol. as a whole predominates over the nature of the metallic element that enters into part of it. In prepg. the cuprosulfites SO_2 was passed through a suspension of $CuCO_3$ until soln. was complete. The rare earth bisulfite was prepd. as before. The solns. were mixed and evapd. at reduced pressure with slight warming. The cuprosulfites of cerium, lanthanum, praseodymium and neodymium, $XCu(SO_3)_2 \cdot 8H_2O$, were pptd. as red microcrystals, insol. in H_2O , $EtOH$ and Et_2O but sol. in acids with the evolution of SO_2 . In prepg. the cuprothiosulfates a soln. of a sol. rare earth salt and a soln. of $CuSO_4$ were satd. with $Na_2S_2O_3$ and mixed. The soln. is dild. after a time and the cuprothiosulfates of cerium, lanthanum, praseodymium, neodymium and thorium, $XCu(S_2O_3)_2 \cdot 8H_2O$, were sepd. as yellow microcrystals. The zirconium salt, $ZrCu_2(S_2O_3)_3 \cdot 30H_2O$, had a different compn. With Th and Zr it was necessary to use absolutely neutral solns. to prevent the pptn. of mixts. of hydroxides and S. In general it was found that the Ce metals combine with complex acid radicals as alk. and alk. earth bases do. This behavior conforms with the high basicity of these elements. In the cuprosulfurous and cuprothiosulfuric acid radicals, besides the alkali metals, only the Ce metals, because of their high basicity, seem capable of combining with these radicals.

E. J. WITZEMANN

Polythionates. I. The decomposition of polythionates in aqueous solution. A. KURTENACKER AND M. KAUFMANN. *Z. anorg. allgem. Chem.* **148**, 43-57 (1925);

C. A. 19, 1111, 2000 and following abstr.—The decompn. of solns. of $K_2S_2O_8$, $Na_2S_4O_8$ and $K_2S_3O_8$ with time in neutral soln. and $NHCl$ is investigated by the methods of analysis published previously. S and the ions SO_3 , S_2O_3 , SO_4 , S_3O_6 , S_4O_6 , S_5O_6 and the acidity are detd. The decompn. follows in terms of ions the reactions: $S_5O_6 \rightleftharpoons S_4O_6 + S$; $S_3O_6 + H_2O = S_2O_3 + SO_4 + 2H$; $S_2O_3 + S_3O_6 + H \rightleftharpoons S_4O_6 + HSO_3$ and in HCl soln.: $S_2O_3 + H \rightleftharpoons HSO_3 + S$. The mixt of tetra- and pentathionate is very stable. Pure tetrathionate forms penta- besides trithionate. Tri- + pentathionate do not form tetrathionate, but trithionate accelerates the establishment of the equil. $S_5O_6 \rightleftharpoons S_3O_6 + S$. IV. The action of alkali on the polythionates. *Ibid* 369–81.—The action of various concns. of $NaOH$ on solns. of tri-, tetra- and pentathionate is investigated by improved methods. The original paper must be consulted for details. J. T. S.

Polythionates. II. The influence of thiosulfate and sulfite on the stability of polythionates. A. KURTENACKER AND M. KAUFMANN. *Z. anorg. allgem. Chem.* 148, 225–31(1925), cf. preceding abstr.—The influence of sulfite and thiosulfate on the decompn. of tri-, tetra- and pentathionate was studied. The decompn. of trithionate is only little influenced, whereas a considerable acceleration takes place in the case of tetrathionate. The action of thiosulfate is here a catalytic one. Thiosulfate shows a tendency to split off S which in turn combines with tetrathionate forming pentathionate, whereas the sulfite formed from the thiosulfate, after the S has been split off, reacts with tetrathionate forming trithionate and thiosulfate. A soln. of pentathionate decomposes quickly in the presence of thiosulfate. A similar action by trithionate is produced on pentathionate. Sulfite and bisulfite reduce the stability of tetra- and pentathionate solns., thiosulfate being quickly formed. III. The action of hydrogen sulfide on polythionates. A. KURTENACKER AND M. KAUFMANN. *Ibid* 256–64.—It is known that polythionates are completely decomposed by alkali sulfides under formation of thiosulfate and free S. The authors studied the less-known reaction between the individual polythionates and H_2S . Thus trithionate reacts very slowly and thiosulfate and free S form. The latter is a decompn. product of thiosulfate produced by H -ions, the formation of which accompanies the transformation of the trithionate into the thiosulfate ion. The velocity of the reaction between tetrathionate and H_2S is greater and diminishes with increasing acidity as in the foregoing case. Pentathionate and free S and occasionally small quantities of thiosulfate are formed. Since pentathionate is formed from tetrathionate and H_2S in acid solns. it is much more stable in the presence of H_2S than tetrathionate. EMIL KLARMANN

The polysulfides and polyselenides of lithium, sodium and potassium. F. W. BERGSTROM. *J. Am. Chem. Soc.* 48, 146–51(1926).—The reactions between S and Se and solns. of Li, Na and K in liquid NH_3 have been studied and the following compds. shown to exist ($M = Li, Na$ or K) M_2S , M_2S_2 , M_2S_4 , M_2Se , M_2Se_2 , M_2Se_3 , M_2Se_4 and higher sulfides and selenides of uncertain compn. R. J. HAVIGHURST

A study of the fluorides and double fluorides of aluminium. MARTIN TOSTERUD. *J. Am. Chem. Soc.* 48, 1–5(1926)—Hydrated Al fluoride of compn. $Al_2F_6 \cdot 18H_2O$ was prepd. from Al hydrate and aq. HF . Anhyd. AlF_3 was prepd. by heating the hydrate to 200° . X-ray photographs show a transition at 115 – 120° . The compds. $4KF \cdot AlF_6$ and $4RbF \cdot AlF_6$ were prepd. in the cryst. form by subjecting the gelatinous substance to a temp. of 270° in a closed system. Two forms of the K salt, one monoclinic and the other orthorhombic, were found; the Rb salt was orthorhombic. Cond. measurements suggest the existence of an NH_4 Al fluoride and Na Al fluoride. R. J. HAVIGHURST

New methods for the preparation of sodium aurothiosulfate. K. LUCILLE MCCLUSKEY and LILLIAN EICHELBERGER. *J. Am. Chem. Soc.* 48, 136–9(1926).— $Na_3Au(S_2O_3)_2$ was prepd. by 2 methods: (1) $CsAuCl_4 + 4Na_2S_2O_3 = Na_3Au(S_2O_3)_2 + Na_2S_4O_6 + 3NaCl + CsCl$; (2) $NaAuCl_2 + 2Na_2S_2O_3 = Na_3Au(S_2O_3)_2 + 2NaCl$. The Au is present in the univalent state. $Na_3Au(S_2O_3)_2$ may be preserved for months if covered with anhyd. ether and kept in the dark in a refrigerator. R. J. HAVIGHURST

The nitrates of bismuth. PICON. *Bull. soc. chim.* 37, 1365–75(1925).—The basic nitrates of Bi are studied especially as regards compn. and dehydration. The observations of Graham, Gladstone, Ditte, Yvon, Rutten, Ruge and Becker are reviewed and the inaccuracy of the usual methods for the detn. of water and HNO_3 is pointed out. The methods of Heintz (*J. prakt. Chem.* 45, 105(1848)) are recommended. The total water can be obtained only by decompn. by heat in the presence of Cu and a desiccant. Vacuum treatment in the presence of Na or P_2O_5 is not effective. The nitrate may be found volumetrically by $FeSO_4$ – $KMnO_4$ titrations before and after oxidation of the $FeSO_4$ by boiling with the nitrate in question. Conclusions: At 100° in a current of O_2 or in an oven, const. wt. does not obtain after 2 months. At the same

temp. but with boiling water, after several exhaustions, $(\text{NO}_3)_2\text{Bi}_4\text{O}_6 \cdot \text{H}_2\text{O}$ may be prepd. At 260° in a current of O_2 , the anhyd. $\text{N}_2\text{O}_5 \cdot 2\text{Bi}_2\text{O}_3$ obtained after 15 days. At 375° in the same gas current, const. wt. results slowly giving $(\text{NO}_3)_2\text{Bi}_4\text{O}_{14}$. At 425° the salt changes completely to yellow, anhyd. Bi_2O_3 . These results differ from the general statement that the anhyd. oxide obtains at 260° . Also in *Compt. rend.* **181**, 516-8 (1925). P. B. PLACE

The hydrolysis of sulfur monochloride. H. L. OLIN. *J. Am. Chem. Soc.* **48**, 167-8 (1926).—The primary reaction is $\text{S}_2\text{Cl}_2 + 2\text{H}_2\text{O} = 2\text{HCl} + \text{H}_2\text{S} + \text{SO}_2$. The existence of H_2S as a product of the reaction has been overlooked by most of the previous investigators. The structure of S_2Cl_2 is probably $\text{S} = \text{S} < \text{Cl}_2$, not $\text{Cl}-\text{S}-\text{S}-\text{Cl}$. R. J. HAVIGHURST

Mercury helide: a correction. J. J. MANLEY. *Nature* **115**, 917 (1925); cf. C. A. **19**, 1827.—The correct analysis of mercury helide showed 21.079 parts by weight of Hg combined with 4.18 parts by weight of He, giving the simplest formula $\text{HgHe}_{1.0}$, not HgHe . FLORENCE N. SCHOTT

The hydrates of Sb_2O_3 (SIMON, POEHLMANN) **2**.

7- ANALYTICAL CHEMISTRY

WILLIAM T. HALL

Phenolphthalein as an indicator for the determination of phosphoric acid by titration of ammonium phosphomolybdate. P. NYSENS. *Bull. soc. chim. Belg.* **34**, 232-6 (1925).—In a brief discussion it is shown that as a result of the large amt. of MoO_3 as compared to the NH_3 and P_2O_5 present, the error introduced into the total titration by the incomplete reaction of the latter 2 substances with alkali, with phenolphthalein as indicator, is less than 1.3%. WM. B. PLUMMER

Advances in the field of metal analysis in 1924. TH. DÖRING. *Chem.-Ztg.* **49**, 1009-12, 1030-3, 1037-40, 1045-8, 1061-4, 1072-3 (1925). E. J. C.

A new confirmatory test for aluminium. H. W. ESTILL AND R. L. NUGENT. *J. Am. Chem. Soc.* **48**, 168-9 (1926).—Dissolve the supposed ppt. of $\text{Al}(\text{OH})_3$ in 6 N H_2SO_4 . Add a little water and enough alkanet root tincture to make the soln. ruby red. Add 6 N NH_4OH until the red soln. changes to blue and 5 cc. in excess. In 5 min. a royal purple lake will rise to the surface and its vol. in cc. is roughly equal to the mg. of Al present. Lakes with other gels appear to be distinguishable from it. W. T. H.

The electrometric determination of tellurium in the presence of ferric iron, selenium and copper. W. T. SCHRENCK AND B. L. BROWNING. *J. Am. Chem. Soc.* **48**, 139-40 (1926).—Te can be oxidized from the quadrivalent to hexivalent state by means of $\text{K}_2\text{Cr}_2\text{O}_7$ and the excess of the latter can be detd. quickly and accurately by electrometric titration with FeSO_4 . W. T. H.

Contributions to the study of ruthenium. IX. Solubility of ruthenium in hypochlorite solutions and an attempt to utilize the reaction for the quantitative determination of the metal. JAS. L. HOWE AND F. N. MERCER. *J. Am. Chem. Soc.* **47**, 2926-32 (1925); cf. C. A. **20**, 344.—Finely divided Ru and its compds. are completely sol. in solns. of alkali hypochlorites and may thus be scpd. from other Pt metals except Os. If an excess of alkali is present, ruthenates are formed; if no excess alkali is present some RuO_4 is formed. From a soln. of K_2RuO_4 , after treatment with Cl, RuO_4 can be completely distd. No satisfactory method was found to ppt. Ru quantitatively in weighable form from RuO_4 . M. O. LAMAR

New procedure for the identification and estimation of cobalt by spectroscopy and chromoscopy. GEORGES DENIGÈS. *Bull. soc. pharm. Bordeaux* **63**, 161-5 (1925).—**Identification of Co.**—Pour into a test-tube 5 cc. of HCl and add 0.1 cc. of a soln. of Co salt contg. 2 g. of Co^{++} per l. A blue color will develop immediately and a direct vision spectroscopy will show clearly the characteristic absorption bands. A blue tint will still be perceptible in a dilution 4 times as great, but the limit for a clear cut spectrum is 0.02 mg. per cc. The absorption bands of the spectrum are not interfered with by the presence of Cu^{++} , Fe^{+++} or Ni^{++} , but if it is desired to bring out the blue color in solns. contg. Cu^{++} and Fe^{+++} , the latter two must be reduced by the addition of SnCl_2 . **Estimation.**—The solns. must be compared with standards on which the following notes are given. An ammoniacal soln. of CuSO_4 contg. 0.20 g. of Cu^{++} per l. has the same intensity of blue as a CoCl_2 soln. contg. 0.04 g. of Co^{++} per l. The tint is not the same, but it

can be made so by the careful addition of $K_2Cr_2O_4$. A soln. contg. 4 g. of Cu^{++} per l. has practically the same tint as a soln. contg. 100 times less of the cation Co^{++} (0.04 g. per l.) dissolved in HCl. A mixt. in the proper proportions of ammoniacal $CuSO_4$ and $K_2Cr_2O_4$ has the same tint as that given by salts of Ni in HCl soln. to which variable quantities of Co^{++} have been added. A. G. DUMÉZ.

Error introduced by the presence of bismuth in the colorimetric determination of iron in minimum: colorimetric method for its determination. H. HEINRICH AND M. HERTSCH. *Glastechnische Ber.* **2**, 112-5(1924); *Chimie et industrie* **14**, 696(1925). In the colorimetric detn. of Fe in Pb_3O_4 by NH_4CNS , there is often obtained a reddish yellow coloration, due to the presence of Bi which, in dil. HCl soln., turns yellow on addn. of NH_4CNS . The Bi can be removed with H_2S without carrying down any Fe with the Bi_2S_3 . The Fe can also be detd. without removal of the Bi by addn. of 5-10 cc. concd. HCl (for 10 g. of Pb_3O_4), which discharges the yellow coloration. The Bi can be detd. colorimetrically as follows: dissolve the Bi_2S_3 ppt. in a little dil. HNO_3 , ppt. with NH_3 , filter, redissolve in a little dil. H_2SO_4 , transfer to a Nessler tube, in a 2nd Nessler tube introduce an equal vol. of dil. H_2SO_4 , add 50 or 100 cc. of 20% NH_4CNS to each tube, and add standard Bi soln. (1 cc. = 0.0002 g. Bi_2O_3) to the 2nd tube until the colors in the 2 tubes are equal. A distinct yellow is obtained with 0.00005 g. Bi_2O_3 in presence of 100 cc. NH_4CNS . A. PAPINEAU-COUTURE.

The detection and estimation of traces of carbon disulfide in small gas volumes. W. J. HUFF. *J. Am. Chem. Soc.* **48**, 81-7(1926).—The method described is capable of detecting 0.02 mg. of CS_2 in 100 cc. of gas mixt. The method was developed from a study of the procedure of Harding and Doran which is suitable for larger quantities of CS_2 and like it depends upon the formation of Cu xanthate: the excess of Cu is detd. iodometrically. W. T. H.

Electrometric titration of alkaloids and the reaction of alkaloid salts. I. M. KOLTHOFF. *Pharm. Weekblad* **62**, 1287-93(1925).—A discussion of the electrometric titration of alkaloids by the cond. method and by the potentiometric method with H, Hg-HgO, quinhydrone and air electrodes. A table of 49 org. bases, mostly alkaloids, is given with their dissociation consts. and the p_H values of 0.01 mol. solns. of their neutral and basic salts. From these data the proper selection of indicator for the titration of a given alkaloid may be easily made. A. W. DOX.

The action of sulfites and of bisulfites on aldehydes and on ketones and its application to the determination of these compounds. GIOVANNI ROMEO AND ELENA D'AMICO. *Ann. chim. applicata* **15**, 320-30(1925).—The method is based on the formation of neutral addn. products of aldehydes or of ketones with sulfites and bisulfites (cf. Tieman, *Ber.* **31**, 3297; Romeo, *C. A.* **13**, 844). *e. g.*, $PhCH:CHCHO + NaHSO_3 + Na_2SO_3 + H_2O \longrightarrow PhCH_2CH(SO_3Na)CH(OH)SO_3Na + NaOH$ and then $NaOH + NaHSO_3 \longrightarrow Na_2SO_3 + H_2O$. *Reagent.*—Add to 400 g. of $Na_2SO_3 \cdot 7H_2O$ in 1000 cc. of H_2O enough satd. $KHSO_3$ soln. (about 160 cc.) to impart an acidity such that 25 cc. is neutralized by about 20 cc. of 0.5 N NaOH (4 drops of 2% rosolic acid as indicator), and heat some hrs. at 100°. *Procedure.*—(1) Titrate 50 cc. of this reagent in the presence of 8 drops of 2% alc. rosolic acid. (2) Neutralize any acidity present in the sample (1-2 g.) with 0.5 N NaOH (using 8 drops of rosolic acid), add 50 cc. of reagent, agitate continually and let stand cold if the sample is sol. or maintain heat if insol. (45 min. for aldehydes, 4-5 hrs. for ketones), cool and titrate the excess acidity with 0.5 N NaOH. Subtract the no. of cc. of 0.5 N NaOH for the last titration from that of the sulfite soln. alone. The difference d corresponds to the quantity of $NaHSO_3$ reacting with the aldehyde or ketone. Then $(100 de)/p$, where e is the wt. of aldehyde or ketone corresponding to 1 cc. of 0.5 N $NaHSO_3$ soln. and p is the wt. of sample, is the % aldehyde or ketone in the sample. Two solns. of $PhCH:CHCHO$ in xylene contg. 66.06% and 50.75% analyzed 65.21 and 50.08%, resp., the low values being in part due to impurities in the $PhCH:CHCHO$ samples. Likewise 2 xylene solns. of pulegone contg. 63.94 and 41.59 analyzed 62.19 and 41.91%, resp. In general the method is preferable to that of Burgess (cf. *Analyst* **29**, 78(1904)). It is not, however, applicable to all compds., for ketones react more slowly than aldehydes and the presence of tertiary or quaternary C adjacent to the CO group retards or even prevents the formation of the hydrosulfone. On the other hand, a Me group on the CO group favors its formation. $PhCHO$ gives low results, perhaps because of the presence of polymers. Menthone does not react and carvone only very slowly, $PhCH:CHCHO$ reacts very rapidly, but pulegone requires 4-5 hrs. for completion. C. C. DAVIS.

Gasometric method for the determination of acetic anhydride. F. L. WHITFORD. *J. Am. Chem. Soc.* **47**, 2939-40(1925).— C_4H_8N is satd. with CO and CO_2 , an excess of $(CO_2H)_2$ added and weighed amts. of Ac_2O are dropped in. The evolution of gas is com-

plete in 15 min. The gas is calcd. into terms of Ac_2O on the basis that 1 mol. Ac_2O gives 1 mol. CO and 1 mol. CO_2 . The method is accurate to within 0.1–0.2%.

EDGAR T. WHERRY

Osmiridium in Tasmania. A. M. REID. *Bull. Tasmania Geol. Survey* No. 32 (1921); *Mineralog. Abstracts* 2, 422.—A detailed account of the occurrences, with analyses.

J. F. SCHAIRES

The structure of sperrylite. W. F. DE JONG. *Physica* 5, 292–301(1925).—From Debye-Scherrer measurements on PtAs_2 crystals de J. found $a_0 = 5.92$ Å. U. For sp. gr. 10.602, the unit cube contains 4 Pt atoms and 8As atoms. Unless *a priori* it is assumed that the 4Pt atoms are equiv. and also the 8As atoms, it is impossible to derive the structural type. If this is assumed, there is dyakisdodecahedral symmetry (T_h^6), pyrite structure, with the parameter $u = 0.38$. For the smallest distance Pt-As is then found 2.47 Å. U; As-As 2.46 Å. U (Ramsdell, in the article abstracted in *C. A.* 19, 3447, obtained the same structure, with $a_0 = 5.91$.) B. J. C. VAN DER HOEVEN

Two new forms of quartz in petrosiliceous porphyrys: lamellar quartz and granular quartz spheruliths. A. DEMAY. *Compt. rend.* 181, 676 8(1925).—A lithologic study.

L. W. R.

Magnesite and kammererite from Low's mine (Line Pit), Cecil County, Maryland. E. V. SHANNON. *J. Wash. Acad. Sci.* 15, 434–8(1925).—A specimen collected on the dump of the mine gave on analysis: MgCO_3 96.26, CaCO_3 2.50, FeCO_3 0.58, insol. and SiO_2 0.28, sum 99.62%. The magnesite appears to be a product of hydrothermal solns. rather than surface weathering, downward-percolating carbonated solns. of meteoric H_2O . Minute quantities of deweylite, which may account for the SiO_2 in the analysis, are deposited in the cavities of the magnesite. Kammererite from Low's Mine was ground and freed in part from chromite and magnesite by means of heavy liquids. Analysis of the partly purified mineral gave: SiO_2 32.28, Al_2O_3 10.64, Fe_2O_3 1.04, Cr_2O_3 2.74, FeO 0.96, CaO 0.06, MgO 38.14, H_2O above 120° 14.84, H_2O below 120° none, sum 100.70%.

W. F. HUNT

Chemical investigations of Japanese minerals containing rarer elements. IV. Analyses of zircon, xenotime and allanite from Ishikawa, Iwaki Province. KENJIRO KIMURA. *Japn. J. Chem.* 2, 73–9(1925); cf. *C. A.* 19, 2008.—[In English.] Zircon and xenotime almost always occur associated or intermingled with each other; they were, therefore, sepd. mechanically. Zircon contains traces of MgO , CaO , MnO ; Al_2O_3 .

0.25%; Fe_2O_3 , 0.95; rare earths, 3.79; SiO_2 , 32.40; ZrO_2 , 58.71; UO_2 , 1.06; P_2O_5 , 1.31; (Cb, Ta) $_2\text{O}_5$, trace; ignition loss, 2.1. The spectrum analysis of the SiO_2 portion showed the lines of Ba and Pb; the ZrO_2 portion showed the principal lines of Ti; the rare earths showed the lines of Yt as predominating, while those of Sc, Nd, Gd, Dy, Er, Yb and Lu were also observed. This mineral is assumed to be an isomorphous mixt. of zirconia, silica and urania, contg. xenotime and silicates of the rare earths as a solid soln. *Xenotime* occurs at Ishikawa often in radial aggregates which resemble chrysanthemum flowers; analysis showed: CaO 0.35, Al_2O_3 0.48, Fe_2O_3 0.23, rare earths 37.37, SiO_2 12.49, ZrO_2 19.84, UO_2 1.92, P_2O_5 23.87, (Cb, Ta) $_2\text{O}_5$ 0.44, ignition loss 2.35%. The spectral analysis resembles that of zircon. This mineral is, therefore, a mixt. of zircon and xenotime. Analysis of an unknown mineral with d. about 3.6, hardness 5.5-6, luster resinous and streak gray, showed it to be *allanite*, which thus also occurs in Ishikawa. **V. Analyses of fergusonite from Hagata, hagatalite from Hagata and oyamalite from Oyama, Iyo Province.** *Ibid* 81-5. The compn. of *fergusonite* from Hagata is practically the same as that reported for Naegi. *Hagatalite* occurs in small crystals 1-5 mm. in diam., imbedded in biotite, yellowish gray, brownish gray or gray, with streak gray. Its hardness is about 7.5, d. 4.4, and it is brittle; a preliminary analysis on 0.2 g. showed: MgO 0.2, CaO 0.3, Fe_2O_3 2.3, Al_2O_3 2.8, rare earths 13.1, UO_2 trace, ThO_2 1.5, ZrO_2 42.0, SiO_2 29.7, (Cb, Ta) $_2\text{O}_5$ 2.7, loss on ignition 5.5%. Spectrum analysis of the rare earth fraction showed the presence of Sc, Yt, Nd, Gd, Dy, Er and Yb; the Yt lines are predominant. This mineral is a variety of zircon. *Oyamalite* resembles naegite and occurs imbedded in feldspar; it is dark green or brown, with streak yellowish or white; its hardness is about 7.5 and d. 4.1. Preliminary analysis of 0.1 g. gave: MgO 0.8, CaO 0.6, Fe_2O_3 0.6, Al_2O_3 2.0, rare earths 17.7, ThO_2 0.6, ZrO_2 40.9, SiO_2 25.7, P_2O_5 7.6, loss on ignition 3.5%. Spectrum analysis showed in the rare earths fraction the presence of Yt, Nd, Gd, Dy, Er and Yb, the Yt lines being predominant. This mineral is also a variety of zircon but is characterized by its high P content.

J. F. S.

Chlorite of the marundites of the Transvaal. J. ORCEL. *Compt. rend.* 181, 795-7(1925); cf. C. A. 17, 2516.—A sample, free of corundum, from Rainbow Camp, southeast of Leydsdorp, contained: SiO_2 27.48, TiO_2 0.12, Al_2O_3 24.00, Fe_2O_3 0.57, FeO 9.42, MgO 26.57, MnO 0.12, CaO 0.15, H_2O at 110° 0.12, $\text{H}_2\text{O} + 12.04$, sum 100.59%. This analysis compared with those of chlorites from North Carolina and Madagascar indicate that they belong to a group of *grochaultites* or *Mg prochlorites* with little Fe.

L. W. RIGGS

The origin of clays. C. W. PARMELEE. *Brass World* 21, 435-6(1925). C. G. F.

Clay material of the quaternary muds. A. DEMOLON. *Compt. rend.* 181, 673-5(1925); cf. C. A. 19, 2868.—The loss of water from samples dried to const. wt. at 100°, then subjected to higher temps., was as follows: at 200° for 1 hr. kaolinite 0, clay material 6.4%, synthetic ferric silicate 9.0, limonite (all) 14.7; at 500° the first 3 minerals had lost 2.33, 10.48 and 11.65% of their water, which was the entire amt. in the ferric silicate and within 0.3% of the entire amt. in clay material. A temp. of 600° was needed to remove practically all the water from kaolinite. On shaking the clay material with standardized lime water, 5.28% of the CaO was absorbed. Kaolin washed with dil. HCl and treated the same way absorbed only 0.25%. The clay material after the removal of the Ca ion allows an exchange of the K ion of KCl with the Al ion. This does not take place with kaolinite. These facts place the aluminosilicate of the clay material, analogous to the marine clays, in the zeolitic silicates with kaolin nucleus and lead to sharply distinguishing kaolinite from kaolin.

Composition of the ash from the eruption on June 12, 1925, of the volcano Acatenango, Guatemala. A. GUTRIER AND H. BRINTZINGER. *Z. anorg. allgem. Chem.* **148**, 141-4(1925).—The ash consists of a gray powder which under the microscope shows an abundance of crystals and much glassy material of various colors. The crystals are of plagioclase, augite and olivine. Chem. analysis of the dry ash gave: SiO_2 60.45, P_2O_5 0.09, TiO_2 0.48, Al_2O_3 19.72, $\text{FeO} + \text{Fe}_2\text{O}_3$ 6.02, CaO 6.38, MgO 0.79, K_2O 0.83, Na_2O 5.17, SrO 0.07. The av. moisture content of the ash was 1.29%. This compn. closely resembles that of volcanic dust found 60 miles from the Santa Maria volcano, Guatemala, Oct. 25, 1902 (cf. Allen, U. S. Geol. Survey, *Bull.* **228**, 273(1903)). L. W. RIGGS

Eruption of Santorin volcano. Morphologic characters. CONST. A. KÉNANAS. *Compt. rend.* **181**, 518-20(1925).—A description of the rapid formation of a dome is given. **Explosive phenomena during the eruption of Santorin volcano.** *Ibid.* 563-5.—The explosions during the formation of the dome are attended by the escape of ashes, incandescent rock and large amts. of H_2O vapor. Combustible gases are evolved as shown by yellow and bluish green flames. The odors of SO_2 and H_2S are observed in the vicinity of the dome. L. W. RIGGS

Igneous geology of the Burntisland district. D. A. ALLAN. *Trans. Roy. Soc. Edinburgh* **53**, III, 479-502(1924).—Analysis of 3 basalts, one dolerite and one picrite indicates their intimate constitutional relationship, and lends strong support to the view that they were derived from one parent magma. L. W. RIGGS

The diabase of the mountains of Saint Croix. J. MOROZEWICZ. *Bull. Serv. Geol. Pologne* **3**, 1-14(1925); *Mineralog. Abstracts* **2**, 433.—Analyses of plagioclase, augite and diabase are given. J. F. S.

A criticism of the application of the theory of assimilation to the Sudbury sheet. T. C. PHERMISTER. *J. Geology* **33**, 819-24(1925).—Field evidence—such as the absence of xenoliths and abnormal rock types—does not confirm the view of G. W. Bain that the norite has assimilated an amt. of rock equiv. to $\frac{2}{3}$ of its original vol. A direct contrast is drawn by comparison with the norite of Aberdeenshire which does show assimilation by a gabbroid rock. W. F. HUNT

The amount of assimilation by the Sudbury norite sheet. N. L. BOWEN. *J. Geology* **33**, 825-9(1925).—Instead of assimilation of extraneous material to explain the salic material added, the same result might be expected by the addition of a siliceous member of the same differentiation series with 68-69% SiO_2 . W. F. HUNT

Carbonate dikes of the Premier Diamond Mine, Transvaal. R. A. DALY. *J. Geology* **33**, 659-84(1925).—These dikes, from 8 to 600 cm. in thickness, are composed of CaCO_3 , $\text{Mg}(\text{OH})_2$ and MgCO_3 and are considered magmatic in origin. The carbonate magma have been derived from heated and dissociated dolomite at depths to which water, serpentine and Fe oxide from the blue ground were added. Expts. with the dike material show its fusion temp. to be below 950° , so that the temp. of the carbonate melt may have been considerably below 900° . W. F. HUNT

The differentiation of sedimentary carbonate rocks. M. RÓZSA. *Kali* 19, 378–83, 406(1925); cf. *C. A.* 19, 2012.—Analyses and mineralogical characteristics of various rocks of this type are given and typical deposits are briefly discussed. WM. B. P.

Report of the laboratory work for 1914–19. Z. SZINYER-MERSE. *Magyar Kir. Földtani Intézet évi Jelentése*, 1917–19, 285–98(1923); *Mineralog. Abstracts* 2, 463.—Analyses of clays, soils, rocks, ores and waters are included. J. F. S.

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, ROBERT S. WILLIAMS

Michel Alexandrovitch Pavlov. LÉON DLOUGATCH. *Rev. métal.* 22, 694–5(1925).—Biographical notes with a brief list of his more important articles. A. P.-C.

Selective flotation at Timber Butte. E. H. ROBIE. *Eng. Mining J.-Press* 120, 685–9(1925).—A résumé of results obtained in efforts to sep. Zn and Pb in complex ores. Mill equipment and a conventional flow sheet are shown, and the Na_2S and NaCN methods of differential flotation discussed. Metallurgical results are governed largely by smelting contracts and other economic considerations. W. H. BOYNTON

Analyzing concentrates graphically. HERBERT ROSE. *Eng. Mining J.-Press* 120, 565–8(1925).—Charts are devised for 3 types of concentrates, whereby the complete mineral constitution of any given set of assays may be read off directly. The types are $\text{CuFeS}_2\text{-FeS}_2$; $\text{Cu}_2\text{S-FeS}_2$; and PbS-ZnS-FeS_2 . The nomographic or alignment chart is preferable to the ordinary coördinate chart. The purpose of the charts is to facilitate quick interpretation of lab. analyses. They are of special value with screen tests. W. H. BOYNTON

Agglomeration of ores at the Seraing (Belgium) plant of the Etablissements John Cockerill. A. COUSIN. *Rev. métal.* 22, 697–702(1925).—A detailed description of the tunnel kiln devised by the Cockerill Co. and in operation at Seraing for the agglomeration of Fe ore for blast-furnace treatment, of its method of operation and of its merits. A. PAPINEAU-COUTURE

The Dwight and Lloyd process for the agglomeration of ore fines. SCHNEIDER & CIE. *Rev. métal.* 22, 703–10(1925).—A detailed description of the installation at the Henri-Paul plant at Montchanin, Saône-et-Loire (France). A. P.-C.

The German nickel industry. H. SIMMICH. *Z. angew. Chem.* 38, 1181–6(1925). E. H.

Treatment in the wet way of sulfurous copper ores. A. MAKOVETSKY. *Messenger technico-économique russe* Nos. 8–9, 660(Aug.–Sept., 1924); *Rev. métal.* 22 (Abstracts), 426(1925).—By treatment of mixed Cu ores with 30–80% H_2SO_4 contg. a proportion of N oxides similar to that permissible in the manuf. of H_2SO_4 , decomn. of the ore starts at about 100°, the N oxides acting as O carriers to the Cu-Fe-S complex, but the pyrites is not attacked. According to the compn. of the complex the solns. obtained contain 1–3 parts of Cu for 2–1 parts Fe and may be treated for the production of $\text{CuSO}_4\cdot 5\text{H}_2\text{O}$ or electrolyzed for production of Cu. A. PAPINEAU-COUTURE

Constitution of mats: copper mats. A. GLAZUNOV. *Chimie et industrie Special* No., 260–2(Sept., 1925).—After giving Meissner's diagram for the ternary system Cu + Fe + S, which considers only the simplest case, G. traces the ternary diagram according to previously published work on the binary systems Cu + S, Fe + S and Cu + Fe. From a discussion of this diagram and of the mechanism of roasting in the light of the diagram G. proposes 50% Cu_2S (approx. 40% Cu) should be the limit between rich and poor mats. A. PAPINEAU-COUTURE

Zinc compounds at high temperatures. W. GEO. WARING. *Mining & Met.* 6, 610–3(1925).—Various methods for the recovery of Zn and other elements from complex sulfide ores by volatilization and subsequent selective condensation are reviewed. Fuming by high-temp. oxidation in conjunction with the ammonium carbonate treatment of the fume gives a cheap, practical method for recovery of all important elements. ALBERT THOMAS FELLOWS

Cyclone dust collectors for recovering zinc oxide. W. C. SMITH. *Eng. Mining J.-Press* 120, 817–9(1925).—Details are given of the design and operation of a cyclone

dust collector which is placed just ahead of the baghouse, whereby 40–68% of the Zn oxide is removed. There is apparently a direct relation between the efficiency of the collector and the vol. of the gas being handled. The oxide burden also has a bearing on the efficiency. Results show that complete removal of dust or fume from metallurgical gases by cyclone separators is improbable. Their use is justified: (1) when heavy dust burden of gases can be reduced thereby, permitting an installation of a smaller and less expensive secondary collector, as a baghouse or Cottrell precipitator; and (2) when a large amt. of cooling surface is required for the gases. W. H. BOYNTON

Relation of ferrous metals. I, II. J. E. FLETCHER. *Foundry* 53, 878–81, 890, 929–33(1925).—A description of the effects of remelting pig iron and the structure relation between the cast, wrought or malleable iron or the steel and the original pig iron. Too little attention has been paid to the homogeneity of pig iron. In the 3 types of pneumatic furnaces, the slags play an important part in controlling not only the compn. of the metal by the thermochem. reactions between the constituents of the metal and the slags, but by phys. conditions, as mobile fluids act as absorbers of certain undesirable migratory constituents such as sulfides and gases and by virtue of their heat cond. or resistivity may aid or resist heat flow from the fuel or heating gases to the metal in contact. Graphs show the ruling types of slags in the transitions from metastable to stable neutral compns. The S content rises rapidly in proportion to the no. of times the metal is remelted and to the amt. of scrap in the mix. Curves indicate the approx. no. of remelts required to reach a point where further remelts do not add much S to the cast products. The max. S content is reached more rapidly as the % of scrap in cupola charges increases. By the same means, the influence of the proportion of scrap on grain growth in the metal cast from similarly remelted pig and scrap mixts. is capable of detn. The oxidation of Fe, Si and Mn can be traced progressively in relation to the no. of remeltings and the pig and scrap proportions in the charges. W. H. BOYNTON

May it be practicable to produce crude iron directly from sulfidic ore? G. N. KIRSEBOM. *Teknisk Ukeblad* 72, 260–1(1925).—Theoretically it is possible to carry out the process in the 3 following steps. (1) FeS_2 is treated with Cl gas, giving in FeCl_2 and S. With an ore contg. 40% S the temp. obtained simply by the heat of reaction should approach 700°. If NaCl is added and some extra heat is applied a fluid fusion is obtained contg. FeCl_2 , NaCl and some ZnCl_2 and CuCl . The S is recovered completely. (2) The FeCl_2 is reduced with C at about 1200° with addn. of CaO. CuCl and ZnCl_2 are evapd. and may be recovered. The heat may be applied electrically. (3) According to expts. made by Solvay and others about 66% of the Cl can be regenerated by heating the CaCl_2 with SiO_2 and O to 15–1600°. NaCl can be recovered from the residue and be used again. Also it might be practicable to regain almost the total necessary amt. of Cl by treating the chloride mixt. with Al silicate in the form of roasted clay or feldspar, at the same time gaining a corresponding amt. of Al_2O_3 in a very cheap way, which may be refined for the manuf. of Al. C. A. ROBARK

Differences in open-hearth boils. H. D. HIBBARD. *Iron Age* 116, 1511–3(1925).—Open-hearth boils are classified according to the degree and violence. The boil is really effervescence and indicates the amt. of free oxide of Fe in the slag, the higher the oxide the harder the boil. Consideration is given of the characters and uses of the 10 recognized types of boils. The 2 succeeding articles cover each degree of boil and its significance and then certain particular cases. W. H. BOYNTON

Ten types of open-hearth boils. H. D. HIBBARD. *Iron Age* 116, 1605–6(1925); cf. preceding abstract.—The boils are grouped from dead bath to Talbot reaction. Five are discussed. W. H. B.

Open-hearth boils of high vigor. H. D. HIBBARD. *Iron Age* 116, 1671–2(1925); cf. 2 preceding abstracts.—Decarburizing effects and the Talbot reaction, effervescing steels and Martin and Siemens processes are included in the last 5 types. The boils considered in this classification are those of ordinary methods and do not include those in which slag is run off and a new slag made. W. H. B.

Waste-heat boilers in steel mills. F. H. WILLCOX AND J. C. HAYES. *Iron Age* 116, 1516–20(1925).—An abstract. Fire-tube boilers lend themselves better to waste heat uses than water-tube boilers, because: water circulation need not be rapid, less space is required and the loose scale falls to the bottom. Because of the low and steady rate of evapn. higher solids are permissible in the water. Installation costs are lower. The water must be carefully treated. A few installations are discussed and some types are illus. Gas-engine waste-heat recovery is more advanced in Europe than in the U. S. Intimate gas scrubbing is important in all cases. There should be a high rate of heat transfer and a low draft loss. Each depends on the mass velocity which is wt. of gas in lbs./hr. divided by the area of gas passage in sq. ft. W. H. BOYNTON

Time of pouring large ingots. J. H. HRUSKA. *Iron Age* **116**, 1305-6(1925).—Knowledge of the relation of time of pouring to temp. is a basis for fundamental improvement in the quality of steel. A time study of various ingots is made. "Time of pouring" is defined as the no. of min. from the first metal in the mold to the moment when the mold is filled to the sinkhead. Curves show the av. time of pouring for large steel ingots to insure best results. The temp. may be regulated so that even a "hot" steel can be poured "colder" by giving a lower speed of pouring. The exact relation of time and pouring temp. and the practical application in making ingot steel will probably be one of the fundamental improvements in quality of forging steel. W. H. B.

Bad castings and furnace scrap. H. H. HOPKINS. *Iron Age* **116**, 1252-3(1925).—The evils attributed to the use of scrap are probably overrated. W. H. BOYNTON

Metallurgy and the chemistry of the solid state. C. H. DESCH. *Chem. Age* (London) **13**, Metall. section, 17-9(1925).—An address describing the progress made in the metallography of pure metals and alloys. H. S. v. K.

Effect of temperature on metals and alloys in the notched-bar impact test. R. H. GREAVES AND J. A. JONES. *J. Inst. Metals* (1925) (advance proof), 17 pp.—Using a Charpy testing machine, G. and J. made notched-bar tests on a number of non-ferrous metals and alloys (Pb, Al, Cu, Sn, Zn, Monel metal, coinage bronze, different brasses, Al bronzes and duralumin). Test pieces were placed in baths or a furnace and kept at const temp. for 30 min and immediately broken. The temp. range was from -80 to 1000°. Curves give the relation between impact figures and temp. These show that when phase changes occur usually a max. or min. is found. Moreover, inflections when found do not necessarily imply a change of phase. The results seem to indicate that a high notched-bar impact figure coincides with good rolling properties. Maxima were found at the hot rolling temps of Zn (150°), Pb-free 70-30 brass (800°), 60-40 brass (715°), Al bronze (about 550°) and duralumin (400°). If such a connection exists there must be an intermediate range of temps. within which behavior on rolling should be worse than it is either at higher or lower temp. Comparative tests of the Charpy and Izod instruments showed that for accurate measurements the first named is preferable. H. S. v. K.

The speed of cementation of copper as a function of temperature. T. PECZALSKI AND A. LAUNFRT. *Compt. rend.* **179**, 887-90(1924).—The optimum temp. for cementation of Cu by Fe in KCl and similar salts is 900°. Temp. and time are the controlling factors. W. A. MUDGE

Cementation of metals by means of volatile salts. THADÉE PECZALSKI. *Compt. rend.* **181**, 463-5(1925); cf. *C. A.* **18**, 3135; **19**, 2022; and preceding abstract.—Cementation of metals by means of salts is more rapid when the salts are volatile at the temp. of the expts., as shown by results obtained with CrCl₃ and NiCl₂ heated in contact with Cu and Fe at 800° for 3-15 hrs. A. PAPINEAU-COUTURE

Cementation of ferrous alloys by chromium. J. LAISSUS. *Compt. rend.* **180**, 2040-3(1925).—Samples of Fe and steel were embedded in powdered ferrochromium (60% Cr and 0.29% C) and heated while protected from the furnace atm. In an ordinary case-hardening steel the following structural zones were found with the microscope. Farthest from the surface was a layer of solid soln. without pearlite, its thickness increasing with temp. up to about 1100°; next was a eutectic zone; and at the surface a brilliant coating, probably Cr carbide, formed above 1000° and increasing with time. The rate of formation of the solid soln. is given by the formula: reciprocal of time = $2.9 \times 10^{-5} \times (1.00695 \text{ raised to a power equal to the abs. temp.})$. Ten-hr. tests with electrolytic Fe and steel of 0.15, 0.40 and 0.85% C, resp., showed that at 1200° the thickness of the brilliant external coating varied inversely as the C content of the steel. At 1000° it was found only on the 0.40 and 0.85% C steels. With the ordinary case-hardening steel and ferrochromiums of different C content, this layer was thickest with the alloy of lowest C, but the thickness of the solid soln. at 1000° increased with the C content of the alloy. When exposed to an oxidizing atm. at 1000°, the plain steel and steel cemented at 1000° oxidized badly in 2 hrs., but steel cemented at 1200° oxidized very little in 37 hrs. The latter also showed good resistance to HNO₃. It is concluded that to obtain good resistance to oxidation or HNO₃, the cementation must be performed above 1100° so as to obtain the brilliant external coating. G. F. C.

Metallurgical developments in the valve and fitting industry. V. T. MALCOLM. *Mech. Eng.* **47**, 1141-3(1925). W. H. BOYNTON

Effects of cold hardening and of quenching on the elastic properties of various metals and alloys. A. PORTEVIN AND P. CHEVENARD. *Compt. rend.* **181**, 716-8(1925).—Modifications in the thermal and mechanical treatment of metals causes relatively small variations (less than 20%) in the modulus of torsion, but the internal fric-

tion, as measured by the decrement, can vary in a 3:1 ratio. This property is of importance for parts subjected to rapidly alternating stresses. A. P.-C.

The viscosity of some alloys when hot. J. COURNOT AND K. SASAGAWA. *Compt. rend.* **181**, 661-2 (1925).—The viscosity limit of a metal at a given temp. is defined as the limiting load below which the metal shows no elongation. Tests were run on various metals (wires 1 mm. in diameter) in an app. allowing of keeping the load const. in spite of the reduction in cross section of the wire and automatically registering the time-elongation curve. At 600°, the following increases in load (in kg. per mm.²) were required to pass from the viscosity limit to a rate of flow of 16×10^{-4} mm. per hr. with test wires 100 mm. long. mild steel 4.2-5.2, semi-mild steel 4.3-5.6, high-speed steel 14.0-19.0, Fe-Ni-Cr alloy (63% Ni, 11% Cr) 32.0-36.0, Si-Cr steel (2% Si, 12% Cr) 30-35.5. The following viscosity limits were found:

Temperature	350°	400°	450°	500°	550°	600°	700°	800°	850°
Mild Steel	31	20	—	8	—	4	—	—	—
Semi-mild Steel	32	21	—	9	—	4	1	—	—
High-speed Steel	—	—	49	30	—	14	7	2	—
Ni-Cr-Fe Alloy	—	—	—	—	42	32	17	7	3
S-Cr-steel	—	—	—	60	45	30	8	1	—

If the curves were plotted and produced, they would cut the resp. tensile-strength curves at the maxima which are present in the latter at temps. of 300-500° according to the nature of the steels, which explains the fall in tensile strengths above these temps.

A. PAPINEAU-COUTURE

The system lead-antimony. II. R. S. DEAN, W. E. HUDSON AND M. F. FOGLER. *Ind. Eng. Chem.* **17**, 1216-7 (1925); cf. *C. A.* **17**, 2813. —The solid soly. of Sb in Pb is 2.45% at the eutectic temp. and 0.8% (or less) at room temp. Alloys contg. more than 0.8% when quenched from elevated temps., age-harden at room temp., as indicated by increase in tensile strength. This behavior is similar to that of duralumin and can be explained in like manner.

H. S. VAN KLOOSTER

Influence of pouring temperature and mold temperature on the properties of a lead-base antifriction alloy. O. W. ELLIS. *J. Inst. Metals* **1925** (advance proof), 18 pp.—E. and his co workers studied the effect of chem. compn., pouring temp. and mold temp. on the micro structure, resistance to compression and hardness in Pb-base bearing metals. Preliminary investigation showed that replacement of Pb by Sb increased the compressive stress and the hardness. Replacing $1\frac{1}{2}\%$ Sn by Cu, E. found that the resistance to compression increased while the hardness scarcely changed. In the final expts. 2 alloys were used contg., resp., 83.1% Pb, 12.1% Sb, 4.8% Sn and 82.5% Pb, 11% Sb, 5.5% Sn, 1% Cu. The pouring temps. varied from 300° to 500°, while the mold was kept at 0°, 100° and 200°. The results obtained were: (1) mold temps. affect the properties referred to much more than pouring temps.; (2) for a given temp. of mold a rise in the pouring temp. causes an increase in the size of the cubical γ -crystals and a coarsening of the matrix; (3) an increase in pouring temp. has less effect on segregation than increase of mold temp.; (4) addn. of Cu has a pronounced effect on the microstructure; (5) the second alloy (1% Cu) shows an intermetallic reaction in the liquid state at 334°.

H. S. VAN KLOOSTER

Hot tensile strength of some copper alloys. M. SAUVAGEOT. *Chimie et industrie Special No.*, 263-76 (Sept., 1925).—The app. and method used are described in detail. Results obtained on Cu, cupro-Mn (4 and 6%), Al bronze (6 and 9%), cupro-Ni (6 and 14%), special brass (Al 3.15, Ni 1.45%) and ordinary bronze at temps. up to 1000°, with various rates of application of the load are tabulated, plotted and commented. The results are not considered sufficiently numerous to warrant drawing general conclusions; but they indicate that the Cu alloys which show best retention of tensile strength at high temps. are solid solns. (cupro-Mn, cupro-Ni) of metals with high m. p. Best results may perhaps be obtained by combining the addn. of Ni and Mn, and perhaps also of small quantities of Fe and Al. The results clearly show the importance of the rate of application of the load. Bibliography of 13 references.

A. PAPINEAU-COUTURE

The effect of low-temperature heating on the release on internal stress in brass tubes. R. J. ANDERSON AND E. G. FAHLMAN. *Engineering* **120**, 754-6, 784-6 (1925).—See *C. A.* **19**, 3457.

H. G.

High temperature-tensile curve, (a) effect of rate of heating, (b) tensile curves of some brasses. D. H. INGALL. *J. Inst. Metals* **1925** (advance proof), 12 pp.—This is a continuation of previous work (cf. *C. A.* **19**, 962) on the effect of rate of heating on the

change in tensile strength with increase of temp. Soft annealed wires of Ag, Al and Cu were subjected to a definite load, which was maintained while the wire was heated in an elec. furnace until it broke. The rates of heating were 3°, 8° and 20° per min. The same type of tensile strength-temp. curve was obtained as previously except that for lower rates of heating the wires break at lower temps. and that a larger number of smaller loops are present. D. thinks that the straight-line portion of the curves is very important to engineers and that beyond the critical inflection loop ending the straight-line portion the material may creep or flow even under small loads. Tensile strength-temp. curves are given for a number of brasses, contg. from 2.6 to 38.34% Zn. Even as little as 2% Zn introduces a second loop in the curve, which is believed to be due to space lattice distortion caused by the introduction of Zn atoms in the Cu lattice. From his curves I. concludes that brasses contg. about 88% Cu or more than 97% or less than 75% will be suitable at 250°. Brasses with about 93 and 80% Cu will resist temps. only up to 200°. These temps. are low and explain why brass used as blades in a turbine rapidly breaks down.

H. S. VAN KLOOSTER

Constitution of copper-zinc alloys containing 45 to 65% of copper. MARIE L. V. GAYLER. *J. Inst. Metals* 1925 (advance proof), 10 pp.—From a careful microscopic study of well-annealed Cu-Zn alloys contg. 47–65% Cu the following conclusions are drawn: the transformation taking place at temps. varying from 446° to 467° is not due to a eutectoid transformation of β into a mixt. of $\alpha + \gamma$. At 446° between approx. 61 and 54% Cu there is the equil. α , β and β' . Above the line $\alpha + \beta$ coexist, below $\alpha + \beta'$. From 54 to 50% Cu and at temps. varying from 446° to 467°, β changes to β' . G. draws a dotted (hypothetical) line below which β' exists. The area between this line and the full drawn line above which β exists represents $\beta + \beta'$ in equil. No change in structure could be detected by quenching from the β -field or the β' -field. Ten photomicrographs and 3 tables are included in the article.

H. S. v. K.

The β -transformations in copper-zinc alloys. J. L. HAUGHTON AND W. T. GRIFFITHS. *J. Inst. Metals* 1925 (advance proof), 9 pp.—The authors have studied the changes of elec. resistance with the temp. for a number of Cu-Zn alloys contg. 62.7–45.7% Cu. The alloys were cast in the dimensions $7 \times 1 \times 1.5$ in., placed in a tubular furnace kept at uniform temp. and the relation between temp. and resistivity automatically registered. The results are in good agreement with the data obtained by Gayler (preceding abstract) and the diagram drawn is very much like Gayler's. There is a horizontal transition line at 453° extending from 62.7% Cu to 54.5%. The change from β to β' takes place at temps. varying from 453° to 470° between the limits 54.5% Cu and 50.5%. From 50.5% Cu to 45.7% Cu (the lowest Cu-contents of the alloys investigated) the transition temp. is 470° (coexistence of β , β' and γ). At room temp. the limits of the β' area are 53.5% Cu and 50%, differing slightly from those existing at temps. between 450° and 470°.

H. S. v. K.

α -Phase boundary in the copper-zinc system. D. STOCKDALE. *J. Inst. Metals* 1925 (advance proof).—As a result of slow diffusion previous workers invariably reported the max. soly. of Sn in Cu in the solid state as too low. Only recently it was found that the soly. was at least 15%. S. redetd. the position of the solidus by slowly heating to the quenching temp., annealing for 2 hr., followed by quenching in water and microscopic examn. Summarizing the results, S. finds that the solidus line extends from the m. p. of pure Cu to a point where the fields of α , $\alpha + \text{liq.}$ and $\alpha + \beta$ meet at 13.3% Sn and 799°. There is another triple point at 15.3% Sn and 590° where the areas of α , $\alpha + \beta$ and $\alpha + \beta'$ meet. A third triple point at 16% Sn and 518° (coexistence of α , β' and δ) marks the extreme limit of soly. of Sn in Cu in solid solution.

H. S. v. K.

Constitution of alloys of aluminium, copper and zinc. D. HANSON AND MARIE L. V. GAYLER. *J. Inst. Metals* 1925 (advance proof), 45 pp.—This work was undertaken (1) to confirm or disprove the existence of the non-variant points 0_1 , 0_2 , 0_3 , 0_4 and 0_5 as found by Jareš (cf. C. A. 13, 2178) and (2) to clear up the discrepancy in the results of Jareš and of Haughton and Bingham (cf. C. A. 15, 2817) with regard to the 0_4 point. Thermal curves were taken of alloys whose Cu content was const. (varying in each series in steps of 5% from 0 to 25%) and whose Al contents varied in steps of 5% from 0–100%. In addn. to the thermal work a detailed study of photomicrographs of well-annealed and slowly cooled samples was undertaken. The results of J. with regard to the 0_1 , 0_2 , 0_3 and 0_4 points were confirmed. The point 0_5 lies apparently outside the field investigated by H. and G., although J. gives its Cu content as 23%. Complete diagrams are given for each of the 5 series of alloys. Indicating the solid soln. rich in Zn by Zn and that rich in CuZn₄ by CuZn₄, the authors find that at the non-variant point 0_5 the following reaction takes place: $\text{liq.} + \text{CuAl} \rightleftharpoons \beta + \text{CuZn}_4$.

Two more non-variant points at which changes in the solid state take place were discovered: α_8 (compn. 9% Cu, 9% Al) at 265°, reaction: $\beta + \text{CuZn} \rightleftharpoons \text{CuAl} + \text{Zn}$ and α_7 (compn. 24% Cu, 21% Zn) at 270°, reaction: $\beta + \text{CuAl}_2 \rightleftharpoons \text{CuAl} + \text{Al}$. The β -transformation of the AlZn system is depressed by the addn. of Cu until the presence of CuAl causes it to take place at 245°.

H. S. VAN KLOOSTER

Physical properties of the copper-cadmium alloys rich in cadmium. C. H. M. JENKINS. *J. Inst. Metals* 1925 (advance proof), 8 pp.—Alloys of Cd and Cu contg. from 0 to 5% Cu (those between 5 and 70% Cu are brittle and useless) were made up in the cast, in the rolled and in the rolled and annealed states. These were tested for density, tensile strength, elongation, hardness, elec. resistance and microstructure. Addn. of 3% Cu raises the tensile strength of pure Cd in the cast state from 5.4 tons/sq. in. to 9.6 tons, while the elongation falls from 50 to 5%. The Brinell hardness increases from 25.5 to 41.5. When more than 3% Cu is added the tensile strength does not materially increase and the elongation becomes very small as a result of the presence of a large proportion of a brittle phase (CuCd)₃.

H. S. v. K.

Properties of some aluminium alloys. HARRY HYMAN. *J. Inst. Metals* 1925 (advance proof), 21 pp.—The object of the expts. was the prepn. of Al alloys which would give good mech. tests when cast in sand molds and at the same time resist atm. and salt-spray conditions. In previous researches too much stress has been placed on mech. tests for chill cast alloys. The quaternary alloys selected were the result more of practical than of theoretical considerations. They were made up by dissolving an alloy of 75% Cu, 15% Ni and 10% Fe and an intermediate alloy or hardener contg. 50% Al, 37.5% Cu, 7.5% Ni and 5% Fe in the required amts. in Al. The alloys used contained about 94% Al, 3.0% Cu, 0.6% Ni, 0.8% Si. In one set of expts. the Fe content was varied from 0.76% to 2.91%. A gradual improvement of mech. properties was noticed up to about 2% Fe. A suitable alloy, which is also reliable under alternating conditions of stress and withstands corrosion in air and sea-spray successfully, had the compn. 93.88% Al, 2.89% Cu, 0.62% Ni, 1.75% Fe, 0.1% Mg and 0.76% Si. In another set of expts. the Mg content of this alloy was varied from 0.1 to 1.03%. An increase of Mg content to 0.5% produces an alloy which responds readily to heat treatment.

H. S. v. K.

Aluminium-silicon alloys (Alpax). A. PETIT. *Compt. rend.* 181, 718-9(1925).—Optimum results were obtained by refining with 0.5-1.0% Na at 775°, and casting at 675° with as rapid cooling as possible, the effects of the Na (up to 1%) being inversely as the rate of cooling. Only part of the Na is used up in the refining proper, the remainder forming a ternary constituent with the Al and Si. None of the special metals tried (K, Ca, Mg, Ce, Zn, Cu, Sb, Ni, Co, Bi, Mn, Sn, Fe, Cd, Pb, 50% CuMg, CuP (15% P)) could replace refining with Na, and addn. of the latter should be made immediately after addn. of the special metal. Even traces of Fe are objectionable. Addn. of other metals (except 2-5% of Cu, Mg, CuMg and MgZn) had little effect. The Brinell hardness, shearing strength, deflection and resiliency after addn. of 2-5% Mg, CuMg and MgZn are tabulated and compared with those of ordinary Alpax. They are affected by heat treatment, especially when sand molds are used, the cooling effects of chill molds being sufficient to harden the alloy. Annealing at 400° for 1 hr. and quenching at 500° decrease the hardness. Aging at ordinary temp. hardens the alloys by pptn. of Mg_2Si or Al_2Cu , as with duralumin; max. hardening is obtained after about 70 hrs.; tempering at 100° accelerates the hardening, but the temp. should not be raised above 125-50° so as not to reduce the hardness.

A. PAPINEAU-COUTURE

Notes on the iron-nickel and iron-cobalt equilibrium diagrams. L. GRENET. *J. Iron and Steel Inst.* 1925 (advance proof), 9 pp.—G. makes a no. of suggestions regarding the diagrams Fe-Ni and Fe-Co, illustrated by some simple exptl. analogies. It might be possible that the α - and the γ -areas are sep'd. by a loop-shaped area in which α and γ are in equil.

H. S. VAN K.

The equilibrium diagram of the iron-carbon-nickel system. TSUTOM KASE. *Sci. Repts. Tohoku Imp. Univ.* 14, 173-217(1925).—Thermal and magnetic analyses, hardness tests, and microscopic exams. are reported for the Fe-Ni system, and the binary equil. diagram is concluded to be of the solid-soln. type. The A_3 change falls steadily with increasing Ni content down to -190° at 35% Ni and occurs in a temp. interval rather than at a point. Ni dissolves C up to 0.55%, forming a eutectic with C at 1318° and 2.22% C. Ni_3C is very unstable and cannot be detected with the microscope. The ternary diagram was worked out and is described and illustrated by a sketch of a model. Photomicrographs of typical structures are also shown. For etching specimens with over 25% Ni either strong HNO_3 or hot HCl was used. No ternary eutectic was found. A binary eutectic contains 4.3% C with no Ni and de-

creasing C down to 0.3% with increasing Ni up to 30%. Cementite occurs in the ternary alloys with 0 to about 30% Ni, with over 0.1% C. With increasing Ni, the A_1 transformation is lowered and is difficult to detect with over 10% Ni, but is almost independent of the C content. With increasing Ni, the A_2 and A_3 points are rapidly lowered and the C content at the eutectoid point decreases down to 0.3% at about 35% Ni. Six plates of curves accompany this paper. G. F. C.

Effect of low manganese contents on the strength of nickel steels. P. DEJEAN. *Chimie et industrie Special No.*, 277-9 (Sept., 1925). —D. shows that, within the range of 0.1–0.5% Mn: (1) with a given C content, the proportion of Ni to which the Mn is equiv. increases with decrease in the Ni content; (2) with a given Ni content, the action of the Mn increases fairly rapidly with increase in C content, attains a max. and then decreases, the max. for various Ni contents occurring at lower C contents as the Ni increases. A. PAPINEAU-COUTURE

Dendritic segregation in iron-carbon alloys. ALBERT SAUVÉUR and V. N. KRIVOBOK. *J. Iron and Steel Inst. (London)* 1925 (advance proof), 6 pp.—A microscopic study was made of the structure of pure electrolytic Fe, melted *in vacuo* and in air. Since no pearlite was found in the sample which on analysis contained 0.06% C, it is inferred that α -ferrite takes up at least 0.06% C in solid soln. In the sample melted in air, Le Chatelier's Cu-reagent failed to show dendritic structure, hence oxygen cannot produce dendritic segregation. On the other hand, the introduction of either P or C, or both together, into Fe results in persistent dendritic segregation. H. S. VAN KLOOSTER

Chromium-iron equilibrium in carbides recovered from annealed 2.23% chromium steels. E. D. CAMPBELL and J. F. ROSS. *J. Iron and Steel Inst. (London)* 1925 (advance proof), 11 pp.—The authors detd. the atomic ratios of Cr, Fe and Mn in the carbides recovered from annealed steels having practically the same ratios of Cr, Mn and Fe, but varying C content. The Cr and Mn contents were 2.23 and 0.24%. The Fe content was around 96%, while the C content varied from 0.36 to 1.62%. The carbides were recovered electrolytically in a soln. contg. 40 cc. of concd. HCl in 1 l. From the data obtained by analyzing the carbides a graph is prepd. giving the atomic percentages of Fe, Cr and Mn as a function of the % C present in the steel. With increase of C, the Fe increases from 70.13 to 90.02%. The Cr decreases from 28.86 to 9.37% and the Mn from 1.01 to 0.60%. A comparison was made of the soly. in α -Fe of the carbides of a Cr steel and those of a pure C steel, both having 0.45% C and both annealed at the same rate. The result was that for the Cr steel the soly. was about 6 times that of the C steel. H. S. VAN KLOOSTER

Effect of other elements upon migration of carbon in steel. E. G. MAHIN, R. C. SPENCER and C. R. HAYNER. *Proc. Indiana Acad. Sci.* 34, 177-80 (1925).—This paper is introductory to an extensive investigation into the influence of other elements on the rate of carburization and C migration. Short discussions of the nature of gray and of malleable Fe and of the case-carburizing process are first given. Rods of ingot Fe were driven into holes in gray and malleable Fe and the samples then heated for 5 hrs. from 750° to 950°. The diffusion of the C was studied with the microscope. The cementation was more rapid from the gray Fe. The expts. are considered to prove that solid C can dissolve in and migrate through Fe. The difference in effect from the 2 kinds of Fe is considered due to differences in C, Mn, or Si content. Further expts. showed that increasing the amt. of silicide or of ferromanganese in a carburizing mixt. of gray Fe drillings increased the tendency of Fe to absorb C. G. F. C.

The formation of martensite in carbon steels. KÔTARÔ HONDA. *Sci. Repts. Tohoku Imp. Univ.* 14, 165-72 (1925).—The A_1 transformation consists of, first, the change of γ -Fe dissolving C into α -Fe dissolving C and second, the change of the latter into ferrite and Fe₃C. During rapid cooling the first change occurs below 300° and the second change cannot occur on account of viscosity at low temp. Thus martensite is obtained. If the second change partly takes place, troostite results. The first change can occur even at low temp., so it is difficult to retain austenite in plain C steels, but this is not true of alloy steels. The C atoms in martensite probably take positions in the center of the face of an elementary cube of the Fe space lattice, causing local distortion and acting like diagonal supporters in the lattice. The position of the C atoms cannot be found with X-rays because of their arbitrary distribution. Ni atoms may act in the same way as C atoms under certain conditions. The diffusion of the X-ray spectrum lines of martensite is explained by the irregular distortion of different parts of the lattice by internal stress and the assumption of very fine crystals is not necessary. G. F. C.

Equilibrium at high temperatures in the iron-carbon-silicon system. M. L. BECKER. *J. Iron and Steel Inst.* 1925 (advance proof), 14 pp; *Engineering* 120,

412-3.—B. has carburized in an elec. tube furnace at temps. varying from 800° to 1100° Armeo Fe, and 3 Fe-Si alloys (C contents 0.1% or less) contg. 1.33, 2.54 and 4.22% Si, resp. The cementing medium was powder obtained from graphite electrodes (99% C). From the carburization curves (% C against time in hrs.) it is seen that most of the C is taken up in the first 40 hrs., the increase for the period from 150 to 300 hrs. being very small. For pure Fe the amts. of C taken up at different temps. agree with those of previous workers above 940°, below this temp., B.'s values are lower. At 900° no C is dissolved. From the isotherms showing the % of C as a function of Si-percentage, it appears that, as Si increases, the soly. of C at const. temp. between 1100 and 940° decreases, the temp. itself having the smaller effect, the higher the Si content. Below 940° the soly. drops rapidly to 0% C, probably around 920°. B. concludes that the graphite-ferrite eutectoid is formed at about 900° and that it contains only 0.05% C.

H. S. VAN KLOOSTER

Heat treatment of steel dies. C. S. SMITH. *Iron Age* 116, 608-810(1925).—Detailed directions, based entirely upon practical experience, are given for the oil-hardening treatment of non-shrinkable and water-hardening steels.

The annealing of electrolytic iron in a vacuum. R. HUGUES. *Compt. rend.* 180, 2043-5(1925).—The evolution of gas and the variations in structure, magnetic and mech. properties of electrolytic Fe were studied under different conditions of heating in a furnace constructed so that the heating element and inner muffle were enclosed in an outer water-cooled tube within which a vacuum of 2 mm. was maintained. For a const. period of 2 hrs., the vol. of gas evolved increased steadily with temp. With const. temp., the vol. evolved increased with time to a max. and then decreased to zero. The sample treated 6 hrs. at 730° gave 30 cc. of gas, or 1.5 times its own vol. This gas was CO₂ 6%, CO 34%, H 50% and hydrocarbons 3%. The curves of magnetic properties, given in a diagram, show more rapid variation than is obtained by heating in an oxidizing atm. The variations in hardness and other mech. properties show the effect of the loss of occluded gas as well as recrystn., the changes commencing at lower temps. and being more gradual than in the normal atm. For metallographic study, repolishing of vacuum-annealed specimens was not necessary. Also in *Rev. métal.* 22, 764-75(1925).

G. F. C.

Influence of strain and of heat on the hardness of iron and steel. ALBERT SAUVEUR AND D. C. LEE. *J. Iron and Steel Inst.* 1925 (advance proof), 7 pp; *Engineering* 120, 433. The authors have performed some interesting expts. on the tensile strength and Brinell hardness of pure Fe and steels (contg. 0.1, 0.3, 0.5, 0.75 and 1.25% C) at temps. between 20° and 600°. The tensile strength slightly decreases around 100° and then rises to a max. at the blue-heat range (between 250° and 400°). Similar results are obtained for the hardness except for the min. around 100°, which is absent in Fe and low-C steels. The increase in strength and hardness in the blue-heat range is ascribed to a strengthening and hardening of the ferrite. The effect of strain on hardness was investigated by testing the hardness near the broken ends of test pieces ruptured at various temps. The hardness is increased the higher the temp. at which the strain occurred, being max. after straining in the blue-heat range. Straining at temps. between 580° and 680° decreases the hardness. This range may be considered the dividing line between hot and cold working. Finally test pieces broken at room temp. were cut in several sections and tested for hardness both in the strained condition and after heating to different temps. The result is a further increase in hardness, with a max. after heating to blue heat. To soften the strained material it is necessary to heat Fe above 425°, 0.1% C steel above 500° and 0.5% C steel above 600°.

H. S. VAN KLOOSTER

A study of the correlation of the remanent magnetism and specific resistance of some pure iron-carbon alloys. I. D. CAMPBELL. *Trans. Faraday Soc.* 1925 (advance proof).—Thirteen test bars were prepd., one of purest electrolytic Fe vacuum-annealed, and 12 of pure Fe with varying C content from 0.05 to 1.50%. These were annealed and hardened in various ways. The specific resistances were measured at 25° between knife edges in the usual way and the remanent magnetism and other magnetic properties were measured by means of a delicate magnetic balance. The specific resistance increases almost proportionally to the C content. The magnetic resistance increases more slowly than the specific resistance up to the eutectoid concn., but more rapidly in hypereutectoid samples. The internal magneto-motive potential increases rapidly with carbide concn. up to 0.6%, after which there is little or no further increase.

S. K. ALLISON

Mechanical and magnetic hardness. K. HEINDLHOFFER. *Iron Age* 116, 606-8 (1925). Alternating-current magnetic readings were taken on a large number of hardened ball-bearing rings, most of which had been heat-treated in quantity production

according to standard shop practice. The method adopted employed a circular current in the ring, with a const. magnetizing current, balanced search coils and only one phase used. The magnetic readings were correlated with mechanical hardness readings detd. by the Rockwell and scleroscope methods. In the av. case, a simple correlation was found to exist within the hardness range investigated. This correlation was greatly improved by taking the mean of six Rockwell readings per ring instead of one. A satisfactory agreement was shown when the two methods of testing were compared on four different lots of fifty rings each which had been given differing heat treatment. Similar results were obtained in the investigation of dented and otherwise defective rings returned to the manufacturer.

D. F. MCFARLAND

Natural water corrosion and hydrogen-ion concentration. J. R. BAYLIS. *Chem. Met. Eng.* 32, 874-5 (1925).—The solubility of iron in alk. natural waters is low (0.1 p. p. m. at a p_H of 8.5) and such waters form an impervious coating of iron oxide in pipping. Pits are covered by tubercles contg. solns. at a p_H of 6.0 and rich in SO_4^{--} and Cl^- .

E. L. CHAPPELL

Carbon dioxide in corrosion of iron. T. FUJIMARA. *Chem. Met. Eng.* 32, 810-11 (1925).—Polished pure iron etched with 5% HNO_3 in alc. remained bright for 15 days under CO_2 -free water, while similar specimens, unetched, rust in 10 min. It is concluded that CO_2 acts in the corrosion process to remove the protective film of $Fe(OH)_2$ at the metal surface.

E. L. CHAPPELL

Influence of metallic elements on the corrosion of iron and steel. YUHATIRÔ UTIDA AND MAKOTO SAITÔ. *Sci. Repts. Tokoku Imp. Univ.* 14, No. 3, 295-312 (1925); [in English].—The authors studied the effect of Ni, Cr, Si, Cu, Mn and W on the corrosion of Fe and steel. The samples were prepd. by casting pure Fe alloyed with the above metals in a metallic mold. The cast alloys were cut in rods 4-5 cm. long and 5 mm. in diam. The clean, polished rods were immersed for 24 hrs. at room temp. in beakers contg. 10% HNO_3 , 10% HCl , 10% H_2SO_4 and the loss of wt. was recorded. Oxidation at high temp. was measured by placing the specimens for one hr. in an elec. furnace at 1100° and recording the increase in wt. The acids used corroded the samples in different degrees. For instance Fe contg. 14% Cr is not attacked by HNO_3 , but is easily corroded by HCl of the same concn. Increasing amts. of Ni, Si and W decrease the corroding action of the acids and the oxidation in air at 1100° . Addn. of Mn always increases the corrosion. Cu increases the attack by HNO_3 , while HCl and H_2SO_4 affect the Cu alloys little or not at all. The combined effect of two metals on the corrosion of Fe and steel gave curious results. While Fe contg. Cr is easily corroded by HCl and Fe contg. Ni very little, the combined effect of both produces alloys highly resistant to HCl and to H_2SO_4 . For steels the best results in HCl were obtained when the C contents varied between 0.1 and 0.7% and in H_2SO_4 when 0.3% C was present. Mixed acids corrode the alloys to a greater extent than the pure acids. An alloy contg. 0.4% C, 20% Cr and 8% Ni, resembling Krupp's rustless steel V₂A, has the best corrosion-resisting properties, both in the pure and in the mixed acids.

H. S. v. K.

The corrosion of tanks containing fused nitrate baths. M. SAUVAGEOT. *Chimie et industrie Special No.*, 280-2 (Sept., 1925).— $NaNO_3$ - KNO_3 baths, frequently used for tempering steels and especially for annealing and hardening Al alloys, attack mild steel from about 500° , the rate of corrosion gradually increasing because of decompn. of the bath with formation of nitrites and liberation of free alkali. A 4:1 KNO_3 - $NaNO_3$ mixt., formerly recommended for quenching light alloys, attacks mild steel even more rapidly than 1:1 $NaNO_3$ - KNO_3 . Chrome steels with high Cr contents resist corrosion up to 650° ; but are not practical because of their cost and difficulty of working. Gray Fe, though less resistant than chrome steels, is far superior to mild steel, especially if the bath is not heated much higher than 500° .

A. PAPINEAU-COUTURE

Action of sodium chloride solutions on ferrous metals. RENÉ GIRARD. *Compt. rend.* 181, 552-5 (1925).—Tests on the corrosion of cast iron and steel immersed in 20-g.-per-l. $NaCl$ solns. showed that: when the soln. is not aerated both the Fe and steel lose wt. steadily and at approx. the same rate; in aerated soln. the steel loses in wt. somewhat more slowly than in non-aerated soln., while with cast iron the oxidation products adhere to the metal and form a protective coating.

A. PAPINEAU-COUTURE

Flue explosions (HAMILTON) 21. Economizes fuel in tinning (FISKE) 21. X-ray examination of inner structure of strained metals (ONO) 2. Use of slag accumulations in industry (ELLERSIEK) 20.

JONES, WM. R.: **Tin Fields of the World.** London: Mining Publications, Ltd. 30s. Reviewed in *Mining J.-Press* 120, 995 (1925).

Treating cupriferous molybdenum ore. NORSKE MOLYBDAENPRODUKTER A.-S. Norw. 41,615, July 13, 1925. After the ore is concd. by flotation the coarser material is screened under a spray of water at high pressure.

Condensing zinc and cadmium. T. GJERSTAD. Norw. 41,476, June 15, 1925. The gas mixt. from a metallurgical furnace is given a spinning rotation by introducing it with a great velocity in tangential direction into the lower part of a vertical cylindrical or conical condenser through one or more slits built tangentially in the circuit of the condenser.

Vanadium from iron ore. D. W. BERLIN. Swed. 58,887, June 10, 1925. The ore is reduced by smelting and the slag is removed. The liquid metal is refined with metallic oxides in such a way that a slag high in V is obtained, from which the V is reduced in the form of ferrovanadium.

Copper from ores. T. J. TAPLIN, W. G. PERKINS AND METALS PRODUCTION, LTD. Brit. 233,029, Jan. 29, 1924. In treating oxidized Cu ore by heating in a reducing gas to render it amenable to leaching with an ammoniacal solvent (as described in Brit. 185,242; C. A. 17, 53), the material is cooled from the reduction temp. in N, CO₂ or other reducing or inert gas, *e. g.* down to 100° or lower.

Desulfurizing and concentrating sulfide iron ores. W. S. MILLAR. U. S. 1,567,378, Dec. 29. Commuted Fe sulfide ore is subjected to the action of SO₂ in a muffle or other furnace, gas contg. steam and at least 50% SO₂, being used. The ore is continually agitated and the temp. is progressively raised but does not exceed 950°. Surface fusion of the ore is thus avoided and Fe₃O₄ is formed.

Iron and sulfur from sulfide ores. H. CONDER. U. S. 1,567,916, Dec. 29. The crushed ore is heated in a closed retort and H is brought into contact with it to reduce the sulfide to FeS. S is recovered from the H₂S produced and the FeS is treated with HCl to form FeCl₂ and H₂S. FeCl₃ and Fe are formed from the FeCl₂ (in diaphragm cells).

Reducing ores and producing cement. A. FERGUSON. U. S. 1,567,934, Dec. 29. A vortex of reducing gases is formed above melting temp. and Fe oxide ore or other finely divided ore is fed in a cloud to the vortex zone. Reduced metal is deposited by centrifugal force on a surrounding wall and collected by gravity in a receptacle below the vortex zone.

Recovery of gold by amalgamation. C. C. HAMILL. U. S. 1,568,276, Jan. 5. A base plate for amalgamation may be formed of Cu and is covered with a mixt. of Hg and Ag filings which produce a rough surface.

Recovering copper from ores. J. W. NEILL. U. S. 1,568,461, Jan. 5. A Cu-bearing soln. formed by treating Cu ore with acid is brought into contact with an aggregate comprising coke and Fe and the resulting product contg. coke and Cu is smelted.

Uranium. R. W. MOORE. U. S. 1,568,685, Jan. 5. In sepg. U from less fusible impurities the metal is fused under inert conditions (*e. g.*, in A) and the fused metal is withdrawn from the less fusible associated material.

Production of volatile metals. H. G. FLODIN AND E. G. T. GUSTAFSSON. Swed. 59,721, Oct. 20, 1925. The finely ground ore contg. one or more sulfides of volatile metals and perhaps other metal sulfides is mixed intimately with metallic Fe in finely pulverized state, for instance spongy iron, pig iron or ferro-alloys, and the mixt. is pressed to briquets, if necessary with a suitable binder. The briquets are heated to such a temp. that the volatile metals will give off their S content to the Fe and are distd. off and taken care of in usual ways. The method is especially suitable to complex zinc ores. Cf. C. A. 19, 2630.

Recovering tin from tinned scrap iron. REYMERSHOLMS GAMLA INDUSTRI A.-B. Swed. 59,566, Sept. 30, 1925. The material is treated with a soln. of CuSO₄ contg. chlorides of alkali or alk. earth metals or both. These latter substances also may be added before or during the process, directly or in the form of other compds. which will form such chlorides when brought together.

Treating metalliferous waste. W. VOOS. Brit. 233,247, Oct. 30, 1924. Brass ashes or slags or similar wastes in the form of dust, sand or sludge, are leached with acid, NH₃ soln. or other reagent which will free them from oxide and the residue is subjected to mech. sepn. to recover free metal.

Ore crusher. J. W. ERICSSON. Swed. 58,857, June 3, 1925.

Open-hearth furnace for chemical and metallurgical operations. A. HELFENSTEIN. Brit. 233,540, June 2, 1924.

Treating zinc powder in a moving container. F. THARALDSEN. Norw. 41,381, May 25, 1925. The container is provided with projections which act upon the pulverulent mass while the container is in motion.

Iron refining. MATHIESON ALKALI WORKS. Brit. 232,963, April 23, 1924. Scrap Fe or other cast Fe is desulfurized by treating the molten metal with soda ash, potash, CaO , BaCO_3 , or MgCO_3 , alone or mixed with CaCO_3 . An app. is described.

"Rustless iron." F. M. BECKET. U. S. 1,567,898, Dec. 29. In making a corrosion-resisting Cr alloy, a low-C metal contg. over 5% Cr and over 40% Si is produced under elec. furnace conditions, and the product is then treated with an oxide such as Cr oxide to oxidize the Si.

Tempering iron articles. HJALMAR LOEFQUISTS ELEKTRISKA A.-B. Swed. 58,967, June 25, 1925. The articles are elec. heated in a closed chamber and cooled by gases or liquids introduced into the chamber, which also exclude the air.

Dephosphorizing iron and steel. I. M. SCOTT and S. PEACOCK. U. S. 1,568,186, Jan. 5. In removing P from Fe and steel, there is added to the molten metal, in a basic open-hearth process, CaCrO_4 , Cr_2O_3 or other O-carrying compds. contg. combined Cr sufficient to dephosphorize a substantial portion of the Fe phosphide present in the mass.

Briquets for treating iron, etc. D. H. CROSSER. U. S. 1,568,271, Jan. 5. Briquets for refining or alloying Fe are formed of finely divided "modifying elements" such as Ni, ferro-Mn, ferro-Si, ferro-Cr and Al disseminated throughout a ceramic binder, *e. g.*, clay.

Silicon manganese chromium steel. AVESTA JERNVERKS A.-B. Swed. 58,966, July 1, 1925. Fe-Mn is added in the Martin furnace immediately before the steel is discharged. The steel is tapped into a large ladle and is here alloyed with Fe-Si and Fe-Cr, which are previously reduced and decarbonized in an elec. furnace.

Steel for railway rails. H. J. FORCE. U. S. 1,568,822, Jan. 5. Rails are made from steel contg. C 0.30-0.85, Mn 1.15-1.90, P not over 0.05, and Si not over 0.30%.

Heat treatment of steel. BRITISH THOMSON-HOUSTON CO., LTD. Brit. 232,970, April 26, 1924. Decarbonization of steel during heat treatment with reducing gases such as H is prevented by coating the steel with Cu, brass or other Cu-contg. metal. The coating may be applied electrolytically or as a separable shell.

Coating steel, etc., with nickel or applying other metal coatings. J. A. SMITH. U. S. 1,567,625 Dec. 29. Articles of steel or other metal to be coated are provided with an intermediate layer of a metal such as Zn, Sn, Cd or Ag having a relatively low m. p. and with an overlying layer of another metal, *e. g.*, Ni, of higher m. p. than the intermediate layer. The article and coating is then heated (to about 315° with steel articles coated with Zn and Ni) to effect an alloying of the metal of the intermediate coating with the metal of the article, without effecting any substantial alloying of the outer layer.

Alloy for metallurgical carbonizing boxes. C. E. MACQUIGG. U. S. 1,568,174, Jan. 5. Carbonizing boxes are formed of an oxidation-resisting alloy contg. Fe, Ni or Co together with Cr 20% or more and Cu 5-7%.

Bearing metals (alloys). J. KARAFIAT. U. S. 1,568,224, Jan. 5. Alloys for bearings are formed of Sn 20-52, Pb 28-68, Sb 12-20% and small quantities of Hg, Bi or Cd.

Nickel copper alloy. J. W. LEHR. U. S. 1,567,066, Dec. 29. A non-corrodible alloy adapted for pipes, valves, etc. comprises Ni 20-40, Sn 1-6, Pb 1-8% and the remainder of Cu, and contains no Zn. Cf. C. A. 19, 2806.

Chemical treatment of articles of low-carbon chromium alloys. AKTIEBOLAGET FERROLEGERINGAR. Swed. 59,171, July 29, 1925. The surfaces are freed from adhering oxides by mech. or electrolytic treatment or by treating with dil. mineral acids, H_2SO_4 or HCl . The articles are then exposed to the action of the dry hydrate of some suitable oxidic acid or a mixt. of such hydrates, for instance concd. H_2SO_4 or H_3PO_4 or both.

Alloy for soldering aluminium. E. D. SCHWALM. U. S. 1,567,396, Dec. 29. An Al solder is prepd. by fusing Cu 15, and Sn 80, with Na 5 parts and then introducing Zn 5 parts.

Selective case-hardening. C. G. WHINFREY. U. S. 1,567,632, Dec. 29. A compn. for use in selective case-hardening comprises fireclay 60, Na silicate 75, kaolin 26, borax 1 and a thinner such as NaOH 3-12 parts which is capable of removing grease and oil from the article treated. This compn. may be used as a C-resisting paint.

Impact test for indentation and hardness. A. L. HAAS. Brit. 233,205, July 31, 1924. Mech. features.

Annealing steel sheets. J. T. HAY. U. S. 1,567,143, Dec. 29. Sheets of chrome steel for annealing are heated in an oxidizing atm. to form a sol. scale on them which may be removed by pickling.

Steel-casting apparatus. D. LARNER. U. S. 1,568,854, Jan. 5. Molten metal is protected from the air while flowing from a ladle to molds.

Pulverizing aluminium or other metals in contact with lubricants. HARTSTOFF-METALL AKT.-GES. HAMETAG. Brit. 232,993, April 28, 1924. If olive oil is added to Al, substantially spherical particles are obtained; with an admixt. of paraffin leaf-shaped Al particles are formed.

Forming continuous soft metal bars from lead or other molten metals. B. S. ELROD and W. HECOR. U. S. 1,567,363, Dec. 29. Mech. features.

Melting metals by a flame from pulverized coal or other solid fuel. W. C. WILLIAMS. U. S. 1,567,219, Dec. 29.

Coating for protecting iron molds. D. H. MELOCHE. U. S. 1,568,234, Jan. 5. A coating compn. is formed of fireclay or other inert refractory compn. mixed with lampblack and with a small proportion of sol. silicate which serves merely as a binder. Cf. C. A. 20, 37.

"Soldering solution." C. B. HULL. U. S. 1,568,669, Jan. 5. A mixt. formed from Sb_2O_3 , HCl , ZnCl_2 and glycerol and H_2O is used.

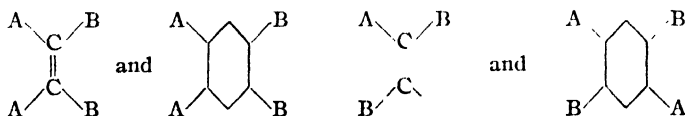

Protecting copper tubes and fittings from corrosion. F. VON WURSTENBERGER. Brit. 233,648, May 8, 1924. Finely divided metals such as Fe, Zn and Al, which are electropositive to Cu, are added to elec. conductive water which comes into contact with Cu tubes, fittings, etc.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

One hundred years of benzene. HELMUT WOLTER. *Gas u. Wasserfach.* 68, 778 (1925). A brief historical discussion. WM B. PLUMMER

Determination of the configuration of geometrically isomeric carbon compounds. A. LANGSETH. *Z. physik. Chem.* 118, 49-64 (1925).—L. draws comparisons between the phys. properties of compds. of the type

with special reference to the m. p., although the b. p., d., n , M_D , soly. in H_2O , dissoc. const. and heat of combustion are considered where such data are available. In general the *trans*-compds. of each series (aliphatic and aromatic) have a higher m. p. than the *cis*-compds. There appears to be no general rule relating the other properties. There appears to be a similar relation in N compds., though the data available are not sufficient thoroughly to test the idea.

Marine animal oils, squalene and spinacene. EMILE ANDRÉ AND HENRI CANAL. *Compt. rend.* 181, 612-4 (1925).—Analysis of the liver oils of *Cetorhinus maximus* (I) and of *Scymnus licha* (II) gave the opportunity to det. whether squalene found by Tsujimoto in I (cf. C. A. 10, 2989; 14, 360) and spinacene found by Chapman in II (cf. C. A. 11, 1420; 12, 1766) are identical compds. The oil of I contained an unsatd. hydrocarbon product which formed 2 *HCl* salts, $\text{C}_{28}\text{H}_{46} \cdot 6\text{HCl}$ and $\text{C}_{30}\text{H}_{50} \cdot 6\text{HCl}$, m. 107-8° and 144-5°, resp. The oil of II likewise contained a hydrocarbon product which yielded 2 *HCl* salts, $\text{C}_{30}\text{H}_{50} \cdot 6\text{HCl}$ and $\text{C}_{31}\text{H}_{52} \cdot 6\text{HCl}$, m. 107-8° and 143-5°, resp. In each case the compd. with the lower m. p. was the more sol. in Me_2CO . On mixing the 2 *HCl* salts which m. 107-8°, the m. p. did not change, in spite of their having different chem. compns. On the contrary the 2 *HCl* salts which m. 143-5° gave a mixt. which m. 139-40°. The results indicate in general that spinacene and squalene are not definite compds. C. J. WEST

Ketopropenes. ATHEY KERNER. *Maryland Acad. Sci. Bull.* 5, No. 2, 10-2 (1925).—A brief general review of properties. About 15 references are given. C. J. WEST

Derivatives of acetyleneglycerol, $\text{HC} : \text{CCH}(\text{OH})\text{CH}(\text{OH})\text{CH}_2\text{OH}$. R. LESPIRAU. *Compt. rend.* 181, 557-8 (1925).—If $\text{HC} : \text{CCH}(\text{OH})\text{CH}_2\text{ClCH}_2\text{Cl}$ (cf. C. A. 19, 813) is treated with dry KOH in Et_2O , the usual method followed in such reactions, an amorphous yellow powder, of high mol. wt. (462 by cryoscopy), contg. Cl and giving a red-brown soln. in HOAc, is formed. But by agitating in the cold with excess 10% aq. KOH *acetyleneepichlorohydrin* $\text{HC} : \text{CCH}(\text{OH})\text{CH}_2\text{Cl}$, is obtained in 85% yield,

liquid, b_{20} 58–60°, d_{20} 1.1592, n_D 1.472, α 28.14° (theoretical 27.60), forms ppts. with the usual reagents of C_2H_2 derivs. On standing several days at 100° with distd. H_2O *acetylene monochlorohydrin* $HC:CCH(OH)CH(OH)CH_2Cl$, is formed, viscous liquid, b_{16} 131–2°, d_{16} 1.289, n_D 1.504, α 30.90° (theoretical 31.22), gives a ppt. with alc. $AgNO_3$ but not with $NH_3 \cdot CuCl$. This compd. gives with $NaOMe$ *acetylenemonomethylin*, $HC:CCH(OH)CH(OH)CH_2OMe$, liquid, b_5 100°, d_{17} 1.120, n_D 1.4720, α 32.56° (theoretical 32.53), gives a ppt. with alc. $AgNO_3$ but not with $NH_3 \cdot CuCl$. These compds. as well as $HC:CCH(OH)CH_2OH$, etc., convert powd. $CuCl$ in suspension in a little H_2O into a yellow powder. Since it is a general characteristic of true acetylenic compds., this reaction with moist $CuCl$ may be utilized to distinguish such compds. particularly since they do not all form ppts. with $NH_3 \cdot CuCl$. C. C. DAVIS

General method of preparation of ethers. J. B. SENDERENS. *Compt. rend.* **181**, 700(1925).—A correction (cf. C. A. **19**, 815). The b. p. of $(Me_2CHCH_2)_2O$ should read 122–4° and not 102–4°. Cf. C. A. **20**, 361. C. C. DAVIS

Substitution by halogen of the hydroxyl in secondary alcohols. P. A. LEVENE AND L. A. MIKESKA. *J. Biol. Chem.* **65**, 507–13(1925).—Although McKenzie and Clough (ref. not given) found that the action of $SOCl_2$ on $MePhCHOH$ was not accompanied by a change of rotation, L. and M. (C. A. **18**, 2494) and McKenzie and Tudhope (C. A. **19**, 814) found that the sign of rotation was changed when $SOCl_2$ reacted with $Me(C_6H_{11})CHOH$. The present study is an attempt to establish in which case the Walden inversion has taken place. *iso*-BuMeCHOH, from Me_2CHCH_2CHO and $MeMgI$, was resolved by conversion into the *H* phthalate (Pickard and Kenyon, C. A. **2**, 993) and recrystd. many times as the brucine salt, the *d*-form sepg. first if the crystn. is interrupted in time; *d*-isobutylmethylcarbinyl *H* phthalate, $[\alpha]_D^{20}$ 51.8°; *d*-isobutylmethylcarbinol, $[\alpha]_D^{20}$ 22.4°; when slowly distd. twice with 4 parts HI (b. 126°) it yields the *iodide*, $[\alpha]_D^{20}$ –18.1°. A portion of the *l*-*iso*-BuMeCHOH (*I*), $[\alpha]_D^{20}$ 7.6°, failed to react when added to $SOCl_2$, but with 0.72 part of C_6H_5N it reacted when $SOCl_2$ was added, first below 50° and at the end of the reaction at 50° for 3 hrs.; the portion of the crude chloride b. 108–14° showed $[\alpha]_D^{20}$ 20.4°. $PhCH_2PhCHOH$ was converted into the cryst. *H* phthalate, whose quinine salt crystd. from $MeAc$ and was extd. with hot $MeAc$ to remove the *l*-salt and recrystd. several times from alc., yielding after decompn. the *d*-phthalate, m. 123°, $[\alpha]_D^{20}$ 25.1°; the *l*-phthalate shows $[\alpha]_D^{20}$ –20°; *d*-benzylphenylcarbinol, m. 64°, $[\alpha]_D^{20}$ 18.5°; a portion with $[\alpha]_D^{20}$ 16.7°, treated in $CHCl_3$ with PCl_5 , gave *l*-benzylphenylchloromethane, $[\alpha]_D^{20}$ –2.1°; a sample of the *l*-carbinol, $[\alpha]_D^{20}$ –9.4°, added to $SOCl_2$, and finally heated under a reflux for 20 min., gave *d*-benzylphenylchloromethane, $[\alpha]_D^{20}$ 7.4°, solidifies below 0°, decomps. above 50° into HCl and $(PhCH)_2$. Like *I*, $MeEtCHOH$ reacts with $SOCl_2$ only in the presence of C_6H_5N and on warming the mixt., the reaction in both cases occurring with reversal of the sign of rotation, but with more racemization than in the cases in which $SOCl_2$ reacts easily. The results show no essential difference in the halogen acids, $SOCl_2$, or PCl_5 , as regards the Walden inversion. M. HEIDELBERGER

Oxidation of secondary mercaptans into corresponding sulfonic acids. P. A. LEVENE AND L. A. MIKESKA. *J. Biol. Chem.* **65**, 515–8(1925); cf. C. A. **18**, 2494; **19**, 1130, 1245. *l*-*iso*-BuMeCHI ($[\alpha]_D^{20}$ –18.1° and –18.6°), heated in 2 expts. at 60–5° with 2 mols. alc. KSH for 5 hrs., gave *2*-mercaptoisohexane, $[\alpha]_D^{20}$ 6.0° and 21.2° resp., variable degrees of racemization having taken place; 5 g., heated under a reflux for 1.5 hrs. with 8 cc. concd. HNO_3 and 2 cc. H_2O , then treated with a little H_2O and evapd. almost dry, repeating until all HNO_3 was removed, and adding excess $BaCO_3$, gave the *Ba* salt of *2*-isohexanesulfonic acid, $[\alpha]_D^{20}$ –4.9° in H_2O (c 10.6); after addn. of HCl , $[\alpha]_D$ of the free acid is –6.7°. Similarly, *l*- $PhCH_2PhCHCl$, $[\alpha]_D^{20}$ –10.7°, with 3 mols. alc. KSH, gave the mercaptan, $[\alpha]_D^{20}$ 8.6°, slowly decomps. above 50° to H_2S and $(PhCH)_2$; oxidized in $MeAc$ with $KMnO_4$ it yielded after removal of the $MeAc$ an oil which was not investigated, and in the aq. layer the partially cryst. *Ba* salt of *1,1*-*di*-phenylethylsulfonic acid, $[\alpha]_D$ –54.0°; after addn. of HCl $[\alpha]_D$ becomes –36.4°. Thus in the cases below in which the changes $RR'CHOH \rightarrow RR'CHCl \rightarrow RR'CHSH \rightarrow RR'CHSO_3H$ have been followed ($RR' = MeC_6H_{11}$, $MeEt$, *iso*-BuMe and $PhCH_2Ph$) the rotations have had the signs $\pm \rightarrow \mp \rightarrow \pm \rightarrow \mp$. Since the differences in polarity between the OH and Cl groups are qual. similar to those between the SH and SO_3H groups, it is concluded that the same configurational relationships exist between the members of these pairs, and that in the cases investi-

gated the alcs. are configurationally related to the halides of opposite rotation, and enantiomorphously related to those of the same rotation. The case of MePhCHOH (see preceding abstr.) will be studied.

M. HEIDELBERGER

β, β', β'' -Triaminotriethylamine and its complex metallic compounds. F. G. MANN AND W. J. POPE. *Proc. Roy. Soc. (London)* 109A, 444-58 (1925).— β, β', β'' -Triaminotriethylamine (I) is prepd. from $\text{C}_6\text{H}_4(\text{CO})_2\text{NCH}_2\text{CH}_2\text{Br}$ and NH_3 by a method based on that of Ristenpart. It may act as a triamine or a tetramine and acts exclusively tetraacidic in its coordination compds. with metals. Two series of coordination compds. have been prepd. and these as derivs. of PtCl_2 and PtCl_4 fall strictly into line with the requirements of Werner's theory. The following derivs. are described. Triaminoethylamine dihydride monohydrochloride, I.2HIHCl ; tricarbamidotriethylamine, $\text{N}(\text{C}_2\text{H}_4\text{NHCONH}_2)_3$, m. 167-8°; triaminotriethylamine trihydrochloride chloraurate, I.3HCl.3AuCl_3 ; tetrahydrochloride chloraurate, I.4HCl.2AuCl_3 , m. 187-9° (decompn.); mercurichloride, I.3HCl.5HgCl_2 , m. 202-4° (decompn.); trihydrochloride rhodochloride $\text{2I.6HCl.3RhCl}_2.6\text{H}_2\text{O}$, m. 280°; tetrahydrochloride rhodochloride I.4HCl.2RhCl_2 ; tetrahydrochloride ruthenochloride $\text{I.4HCl.2RuCl}_3.2\text{H}_2\text{O}$; trihydrochloride platinumchloride $\text{2I.6HCl.3PtCl}_2.3\text{H}_2\text{O}$; trihydrochloride platinumchloride $\text{2I.6HCl.3PtCl}_4.10\text{H}_2\text{O}$, m. 280° (decompn.); tetrahydrochloride platinumchloride, $\text{I.4HCl.2PtCl}_4.10\text{H}_2\text{O}$, m. 271-3° (with decompn.); dichlorotriaminotriethylamine-platinic dichloride, $[\text{Cl}_2\text{PtI}]\text{Cl}_2$, m. 263-6° (decompn.) dichlorotriaminotriethylamine-platinic diiodide, $[\text{Cl}_2\text{PtI}]\text{I}_2$, m. 233-7° (decompn.) dichlorotriaminotriethylamine-platinic platinumchloride, $[\text{Cl}_2\text{PtI}]\text{PtCl}_6.\text{H}_2\text{O}$, m. 287-8° (decompn.); dichlorotriaminotriethylamineplatinic platinocyanide, $[\text{Cl}_2\text{PtI}]\text{Pt}(\text{CN})_4$; triaminotriethylamineplatinous platinumchloride, $[\text{PtI}]\text{PtCl}_4$, m. 270-5°; triaminotriethylamineplatinous diiodide, $[\text{PtI}]\text{I}_2$, m. 267-9° (decompn.).

REYNOLD C. FUSON

The trithioacetaldehydes and the mechanism of their rearrangement. EMIL FROMM AND LEON ENGLER. *Ber.* 58B, 1916-24 (1925).—Mann and Pope (*C. A.* 17, 2558) by the action of S_2Cl_2 or SCl_2 on α -trithioacetaldehyde (α -I), m. 101°, obtained $(\text{MeCHCl})_2\text{S}$ (II), which with NaOH , Ag_2O , Ag_2S or H_2S gave a cryst. product, m. 81°; this they believed to be identical with Marckwald's (*Ber.* 19, 2378 (1886)) and Poleck's and Thummel's (*Ber.* 22, 2871 (1889)) γ -I, and in proof of its purity they state that it can be prepd. in various ways and that its m. p. changes neither on sublimation nor on crystn. from Me_2CO . As, however, the existence of 3 isomeric I would render untenable the theory as to the stereoisomerism of the I proposed by Baumann and Fromm (*Ber.* 24, 1457 (1891)), who found that the γ -I of Marckwald and of Poleck and Thummel is only an impure α -I and yields pure α -I on crystn. from Me_2CO , F. and E. have again taken up the study of the I. They for the 1st time have succeeded in obtaining unmistakably different α - and β -derivs. (iodides and sulfoxides) of I. α -I with I gives a stable diiodide (α -III) and β -I a less stable isomer (β -III), each of which with AgOAc regenerates the original I. The reaction can be used to detect α - and β -I in mixts.; from such mixts. the α -I can even for the most part be recovered quite pure by converting it into the diiodide and then treating it with AgOAc , but in the case of the β -I this is not always possible because the β -III is much more sol. and when any α -I is present it comes down as α -III with the β -III. α -I with the calcd. amt. of perhydrol in AcOH gives a trisulfoxide (α -IV), m. 184°, while β -I yields an isomer (β -IV), m. 153°; a mixt. of the two m. 120-35°. The only reducing agent which converts the IV back into I is concd. HI which at the same time exerts a rearranging action, so that both α - and β -IV yield β -I; likewise further oxidation of both IV yields the same trisulfone. Attempts to prep. a III from the so-called γ -I gave pure α -III, and similarly oxidation with H_2O_2 gave pure α -IV. Contrary to Mann's and Pope's statement, their " γ -I" can be sepd. by very cautious fractional crystn. from Me_2CO into 2 substances, viz. α - and β -I. Expts. with artificial mixts. of these 2 compds. showed that a mixt. contg. 2 parts α - to 1 part β -I yields a sublimate m. 78-80°. To obtain such a mixt. it is not necessary to follow the roundabout way used in prepg. the supposed γ -I; it is sufficient merely to treat HCl solns. of AcH with H_2S . These results show that there are in reality only 2 forms of I. The labile I are converted by exhaustive oxidation into the sulfones of the stable forms, and likewise the labile I are rearranged by small amts. of I or MeI into the stable I. It can easily be shown by means of models that this rearrangement cannot be explained by assuming addn. of the reagent (I or MeI) with rupture of the I ring at one point, followed by splitting off of the addendum and reclosure of the ring in a different direction; the rearrangement requires the assumption of a demolition of the whole ring structure and its reconstruction in a different configuration. Such a demolition and reconstruction doubtless occurs in the prepn. of II from I and of I from II. II can be obtained from β - just as well as from α -I with S_2Cl_2 or SCl_2 , and since it can

readily be converted into α -I, this for the 1st time makes it possible to obtain a labile from a stable form. Both trimol. I, therefore, with S_2Cl_2 or SCl_2 give the monomol. II (demolition of the ring) which with H_2S or similar reagents forms the trimol. α -I (reconstruction of the ring). Both IV, boiled with KOH and concd. somewhat in a vacuum desiccator, yield the same *disulfoxide sulfide*, $MeCH_2S.CHMe.SO\ CHMe.SO$,

turns brown above 220° , m. 255° (decompn.), which is converted by HI into β -I and by $KMnO_4$ or H_2O_2 into the trisulfone, while weak reducing or oxidizing agents do not attack it. α -III (4.5 g. from 3 g. α -I and 4.2 g. I in a little Et_2O), red, m. $76-8^\circ$. β -III, from β -I and I in AcOH, red-brown, loses I in the air or *in vacuo*. C. A. R.

Influence of phosphates on the oxidation of butyric acid with hydrogen peroxide. E. J. WITZEMANN. *J. Am. Chem. Soc.* **48**, 202-8 (1926).— $PrCO_2H$ in the presence of enough KOH to neutralize it is oxidized by H_2O_2 in the presence of di- and mono-alkali phosphates. In the presence of monoalkali phosphate the oxidation is slower and there is perhaps a somewhat larger relative production of Me_2CO than with the dialkali phosphates. In the presence of dialkali phosphates the oxidation is much faster and Me_2CO , AcOH and CO_2 are the products isolated when the oxidation of the acid is complete. The AcOH obtained in the 1 case recorded was 37% of that corresponding to complete oxidation of the acid to AcOH and CO_2 . This formation of AcOH is thought to be the result of oxidation of the acid at the α -C atoms (see following abstrs.).

C. J. WEST

Simultaneous oxidation of glucose and butyric acid. E. J. WITZEMANN. *J. Am. Chem. Soc.* **48**, 208-11 (1926).—When glucose and $PrCO_2K$ are oxidized simultaneously with H_2O_2 in the presence of phosphates, the oxidation of the K salt is not influenced by the presence of glucose; it is more quickly oxidized than glucose; the glucose exercises no antiketogenic effect like that observed in the organism. C. J. W.

Oxidation of α - and β -hydroxybutyric acids with hydrogen peroxide. E. J. WITZEMANN. *J. Am. Chem. Soc.* **48**, 211-22 (1926); cf. preceding abstrs.—The oxidation of α - (I) and β -hydroxybutyric acids (II) with H_2O_2 in the presence of phosphates and with $KMnO_4$ in the presence and absence of alkali, was studied in order to interpret results on the oxidation of $PrCO_2H$ previously described. I is more easily oxidized under all conditions tested than II, as well as the chem. related $AcCH_2CO_2H$ and Me_2CO . Unlike $MeCH(OH)CO_2H$, which reacts almost entirely with $KMnO_4$ in the absence of alkali to give AcOH, CO_2 and H_2O , I in only 1 expt. underwent oxidation, giving $EtCO_2H$ and CO_2 in sufficient amts. so that its presence among the other products could be proved. Generally, so much AcOH was formed that no evidence of the formation of $EtCO_2H$ was obtained. With H_2O_2 in the absence of phosphates no evidence of $EtCO_2H$ formation from I could be obtained. Oxidation to AcOH and CO_2 took place according to the reaction: $I + 5O = AcOH + 2CO_2 + 2H_2O$ at room temp. in the absence of alkali. II was oxidized with $KMnO_4$ with a measurable velocity only in the presence of an excess of alkali. It was not appreciably oxidized with H_2O_2 in the presence of phosphates. The results with alk. $KMnO_4$ correspond closely to the reaction: $II + 5O = AcOH + 2CO_2 + 2H_2O$. Former expts. on the oxidation of Me_2CO with $KMnO_4$ showed that, in the oxidative breakdown of $MeCOCO_2H$ which is an intermediate in the oxidation of Me_2CO , $MeCH(OH)CO_2H$ and $CH_3(CH_2OH)_2$, there is a shift from a loss of 1 C atom as CO_2 , by the C chain, to a loss of 2 C atoms as $(CO_2H)_2$, on increasing the concn. of alkali in the soln. and a corresponding diminution of the production of AcOH. This change is definitely associated with the formation of isopyruvic acid by the shifting of a H atom in the Me group of $MeCOCO_2H$. A corresponding enolization is thought to be involved in the oxidation of I and II when the chain is shortened by 2 C atoms. The greater lability of the H on the CH_2 group in $EtCOCO_2H$ accounts for the greater tendency of this intermediate to enolize and consequently lose 2 C atoms rather than 1, as it is commonly thought to do. The results give definite chem. grounds based on expts., as closely analogous to biol. conditions as is so far possible, for considering α -HO and α -CO fatty acids as normal intermediates in oxidative metabolism. Such a suggestion harmonizes general chem. experience with biol. observation and sets the "acetone bodies" in a separate compartment both chem. and biol. The "acetone bodies" are known to be burned in the organism with relatively great difficulty and have now been shown to be difficultly oxidized chem. in comparison with other possible intermediates, that have now been shown to explain the known facts of fat oxidation equally well. These expts. do not reveal how glucose burning in the organism can prevent the formation or complete the oxidation of the "acetone bodies."

C. J. WEST

Configurational relationship between β -hydroxybutyric acid and lactic acid. P. A. LEVENE AND H. L. HALLER. *Science* **62**, 356 (1925); cf. *C. A.* **19**, 3253.—*l*- β -Hydroxy-

butyric acid is configurationally related to *l*-propyleneglycol; *i. e.*, the asym. C atoms in these 2 substances have the same configuration when they rotate polarized light in the same direction. Reduction of Et lactate with Na and EtOH gives a glycol, which rotates in the same direction as the original free lactic acid; the same relationship holds here. Lactic acid with $[\alpha]_D^{20}$ 0.7° gave an Et ester with $[\alpha]_D^{20}$ -2.5° and a glycol with $[\alpha]_D^{20}$ 0.6°.

C. J. WEST

Decomposition of esters of secondary alcohols. A. MAHLE. *Caoutchouc & gutta-percha* 22, 12937 9(1925). It has already been shown (*Compt. rend.* 152, 669 (1912); 154, 49, 175(1913)) that esters of primary alcs. and monobasic acids decomp. in the presence of catalysts (oxides), the products varying with the oxide used. Similar expts. are now described which deal with the decompn. of esters of secondary alcs. and mono-basic acids, including $\text{MeCO}_2\text{CHMe}_2$ (I), $\text{MeCO}_2\text{CHMeEt}$ (II), $\text{MeCO}_2\text{CHMePr}$ (III), $\text{PhCO}_2\text{CHMe}_2$ (IV) and $\text{EtCO}_2\text{CHMeEt}$ (V). Action with Al_2O_3 —I at 360° formed a gaseous mixt. contg. in %: CO_2 12, C_3H_8 80, H 12 [does not add to 100—ANSTR.] with a liquid composed of H_2O , Me_2CO , HOAc and undecompd. I, indicating that the alc. function is more completely attacked than the acid and that Al_2O_3 has the same effect as TiO_2 with primary alcs. III at 380° was relatively stable and only partial decompn. occurred. The small vol. of gas formed contained 34% CO_2 and 60% pentene and the liquid condensate more pentene, Me_2CO , HOAc and undecompd. III. Action with ThO_2 —II at 380° gave a large vol. of gas contg. in %: CO_2 + H_2O 52, C_3H_8 47, H 1 and a liquid composed of Me_2CO , EtCH(OH)Me and undecompd. II, indicating an action similar to that of ThO_2 with primary alcs. III gave a gas contg. in %: CO_2 72, pentene 25 and H 3 and a liquid contg. a large amt. of pentene, PrCH(OH)Me and undecompd. III. The small amt. of H probably arose from decompn. of a small amt. of butanol to EtMeCO , which was difficult to identify because of its similarity to Me_2CO . IV at 400° decompd to MeCH_2CH_2 and BzOH . Action of TiO_2 —I at 370° formed a gas contg. in %: CO_2 18, propylene 64, H 8 and a liquid contg. Me_2CO , HOAc and undecompd. I. The chief reaction was probably: $\text{I} \rightarrow \text{HOAc} + \text{C}_3\text{H}_8$, followed by partial decompn. of the HOAc to Me_2CO . II at 400° decompd. in a similar way, the gas contg. 40% CO_2 and 50% butylene and the liquid a large amt. of HOAc, a small amt. of Me_2CO , undecompd. II and dissolved butylene. The evolution of gas from III was very slow, the gas contg. 55% CO_2 and 30% pentene and the liquid a large amt. of HOAc a little MeAc and dissolved pentene. V at 380° gave a gas contg. 18% CO_2 and 78% C_3H_8 and a liquid contg. a large amt. (about 1/3 of the product) of EtCO_2H and a small amt. of propylene. Below 400° then, the action with TiO_2 is predominantly $\text{RCOOC}_n\text{H}_{2n+1} \rightarrow \text{RCO}_2\text{H} + \text{C}_n\text{H}_{2n}$. Some RCO_2H then decomp. thus: $2\text{RCO}_2\text{H} \rightarrow \text{R}_2\text{CO} + \text{CO}_2 + \text{H}_2\text{O}$, this last reaction becoming more extensive with increase in temp. With all 3 catalysts the reactions are in general similar below 400° to those with primary alcs., in that the products vary with the catalyst, but above 400° the reaction products decomp. in turn, the acids into ketones and the alcs. into ethylene hydrocarbons.

C. C. DAVIS

Synthesis of *N*-methylputrescine and of putrescine. H. W. DUDLEY AND W. V. THORPE. *Biochem. J.* 19, 845-9(1925).— δ -Iodo- (and δ -bromo)butylamine can be benzoylated almost quant., the $\text{I(CH}_2)_4\text{NHBz}$ so obtained being converted to monobenzo-*N*-methylputrescine, $\text{BzNH(CH}_2)_4\text{NHMe}$, by the action of MeNH_2 , the free base, $\text{H}_2\text{N(CH}_2)_4\text{NHMe}$, being obtained by hydrolysis with HCl. By using NH_3 in place of MeNH_2 putrescine can be prepd.

BENJAMIN HARROW

Numerical values of the optical rotation of methylated gluconic acids and their salts. P. A. LEVENE AND G. M. MEYER. *J. Biol. Chem.* 65, 535-44(1925).—As in all the α -OH and NH_2 acids in which the allocation of the OH (or NH_2) group is the same as that on carbon 2 of gulonic acid, the present work shows that in the methylated gluconic series, the rotations of the free acids are to the left of those of their metallic salts. Benzylidenemethylglucoside, prepd. by a slight modification of the method of Irvine and Scott (*C. A.* 7, 2383), was converted into the 2,3-di-Me deriv. and this hydrolyzed to 2,3-dimethylglucose; the crude product, oxidized with Br until it no longer reduced Fehling soln., yielded 2,3-dimethylgluconic lactone, $[\alpha]_D^{20}$ 58.5° in aq. alc.; for the α of the Na salt, 0.4 g. was heated at 80-90° for several hrs. with 2.5 cc. *N* NaOH and made up to 5 cc. with H_2O , $[\alpha]_D^{20}$ 44.1°; 4 cc. of this soln., cooled with ice-alc., neutralized with 2.25 cc. *N* HCl, and made up to 10 cc., gave $[\alpha]_D^{20}$ of the free acid as 22.5°; after 24 hrs. $[\alpha]_D^{20}$ showed lactonization to be almost complete. This procedure was used for the detn. of α in the Na salts and free acids below. Monoacetoneglucose, with Me_2SO_4 and 30% NaOH, gave 3,5,6-trimethylmonoacetoneglucose, b_D 110°, n_D^{23}

1.44914; after hydrolysis the crude trimethylglucose yielded 3,5,6-trimethylgluconic lactone, b_1 155°, initial $[\alpha]_D^{20}$ in aq. alc., 44.1°, after 24 hrs., 39.8°; $[\alpha]_D^{20}$ of the Na salt, 24.0°; acid, $[\alpha]_D^0$ -6.3° after 24 hrs., 5.4°. 2,3,5-Trimethylgluconic lactone, b_{0-14} 142°, $[\alpha]_D$ in aq. alc. 90.8°, after 24 hrs., 55.0°; Na salt, $[\alpha]_D^{20}$ 64.4°; acid, $[\alpha]_D^0$ 19.3°, after 24 hrs., 23.5°. Tetramethylgluconic lactone, b_{0-8} 128°, $[\alpha]_D^{20}$ in aq. alc., 106.1°, after 24 hrs., 52.2°; Na salt, $[\alpha]_D^{20}$ 76.4°; acid, $[\alpha]_D^0$ 43.0°, after 24 hrs., 49.5°. Ca gluconate, with Me_2SO_4 and NaOH, then 3 methylations with $MeI-Ag_2O$, hydrolysis, and further treatment with $Me_2SO_4-Ag_2O$, followed by acidification and extn. with Et_2O , gave pentamethylgluconic acid, b_1 155°, $[\alpha]_D^{20}$ in H_2O , 22.5°; Na salt, $[\alpha]_D$ 53.7°. From these values it is calcd. that the changes in $[M]_D$ of gluconic acid due to methylation of carbons 2, 3, 4, 5 and 6 are, resp., 134.88°, -63.02°, -50.46°, 55.16° and 39.14°. That structural rigidity explains the fact that the salts of the 2,5-anhydro-sugar acids show the same $[M]_D$ as the acids is also supported by these results, since in some of the cases the 2 and 5 H atoms have also been substituted. M. HEIDELBERGER

Composition of pectin: a preliminary report on the determination of galacturonic acid in pectin. W. H. DORE. *J. Am. Chem. Soc.* **48**, 232-6 (1926).—A modification of the Lefèvre-Tollens method for glucuronic acid has been applied to the detn. of galacturonic acid in pectic substances. The same samples were extd. with 70% EtOH and the furfural yields of the residues were detd. Comparison of the results by the 2 methods show that apparently no simple relation exists between the galacturonic acid and furfural yield so obtained. A possible interpretation of the data is discussed with reference to Nanji, Paton and Ling's hexa-ring structure for the basal unit of pectic substances (*C. A.* **19**, 2327). C. J. WEST

Anode phenomena in the electrolysis of potassium ethyl malonate. J. B. ROBERTSON. *J. Chem. Soc.* **127**, 2057-67 (1925); cf. Gibson, *C. A.* **19**, 1406.—From a study of the anode potential, the current, and the compn. of the gases evolved in unit time during the electrolysis of N solns. of $EtO_2CCH_2CO_2K$ with various electrodes and with gradually increasing applied e. m. f., R. confirms the view that the synthesis of $(CH_2CO_2Et)_2$ at the anode is the result of the electrolytic oxidation of 2 mols. of $EtO_2CCH_2CO_2H$. With anodes of polished Pt the synthetic reaction occurs only when the anode has acquired a potential of 2.3-2.4 v (H standard). Gray Pt behaves similarly. With anodes of platinized Pt and Au, there is no synthesis, but above 3.3 v. complete oxidation takes place in the former case, while even above 6 v. there is little oxidation in the latter case. It is shown that there is complete oxidation of a portion of the electrolyte with all the anode materials used even at very low potentials. This is small for platinized Pt and Au but considerable for smooth and gray Pt. With Au anodes a peculiar instability is observed between 5.0 and 6.2 v., which is attributed to the formation of an unstable oxide of Au. R. E. GIBSON

Stereochemical studies. VIII. Optically active α,α' -dibromoadipic acids. BROR HOLMBERG AND EMIL MÜLLER. *Ber.* **58B**, 1601-4 (1925); cf. *C. A.* **20**, 372.—Two optically inactive α,α' -dibromoadipic acids, m. 193° and 139°, resp. have been known: for some time and controversy as to which was the *meso*- and which the *dl*-form has existed. H. and M. show that the higher melting acid cannot be resolved into optically active components, whereas the lower melting acid may be resolved, by progressive formation of the salt with *l*-MeCHPhNH₂, recrystn. and recovery of the acid with HCl, into *d*- α,α' -dibromoadipic acid, $[\alpha]_D^{180}$ 66.3°, m. 151-3°, and the *l*-isomer, $[\alpha]_D^{180}$ -65.1°, m. 151-3°. Hence the lower melting acid is the *dl*-form. From a soln. of 0.1818 g. *l*-form and 0.1785 g. *d*-form in ether a *dl*-acid, m. 143-4°, crystd. out. R. E. GIBSON

Some ether-substituted derivatives of diethyl malonate and barbituric acid. A. J. HILL AND DEW. T. KEACH. *J. Am. Chem. Soc.* **48**, 257-62 (1926).—*Bu* chloromethyl ether, b_{760} 134°; *iso-Bu* deriv., b_{760} 120-1°; *benzyl* deriv., b_{40} 125°; the yields were 37, 35 and 77%, resp. The following substituted *Et* malonates were prepd.: Methoxy-methyl, b_8 95-100°; *bismethoxymethyl*, b_8 120-30°; *ethylmethoxymethyl*, b_{18} 125-6°, 69% yield; *ethylethoxymethyl*, b_{13} 120-1°, 74%; *Et propoxymethyl*, b_{16} 135-40°, 50%; *ethylbutoxymethyl*, b_{8-9} 133°, 50%; *ethyl isobutoxymethyl*, b_{9-10} 135°, 56%; *ethylbenzyloxymethyl*, b_{10-11} 190-2°, 56%; *propoxymethyl*, b_{2-3} 107-8°, 21%; *bisethoxymethyl*, b_{7-8} 123-5°, 25%; *bispropoxymethyl*, b_{2-3} 124-5°, 21%. These derivs. condense normally with $CO(NH_2)_2$, giving the following 5,5-barbituric acid derivs.: *ethylmethoxymethyl*, m. 184°, 35% yield; *ethylethoxymethyl*, m. 166°, 37%; *ethylpropoxymethyl*, m. 174°, 48%; *ethylbutoxymethyl*, m. 135°, 45%; *ethylisobutoxymethyl*, m. 177°, 56%; *ethylbenzyloxymethyl*, m. 139-40°, 33%; *bis[ethoxymethyl]*, m. 201-3°, 63%; *bis[propoxymethyl]*,

m. 187°, 44%; 5-propoxymethyl, m. 163-5°, 44%; 5,5-ethylethoxymethylthio, m. 147°, 88%.

C. J. WEST

Manufacture of calcium citrate and citric acid from lime juice. F. H. S. WARNEFORD AND F. HARDY. *Ind. Eng. Chem.* **17**, 1283-6(1925).—Citric acid from crude Ca citrate is dark in color, as a result of atm. oxidation of phlobatannins in the com. product. The amt of phlobatannins retained by the crude citrate may be reduced by pptg. the lime juice cold with a thin cream prepd. from finely ground CaO, contg. enough alkali to neutralize the acid and then raising the temp. to boiling before filtration. Perfectly colorless citric acid may be obtained by neutralizing the defecated juice to p_H 3.8 with Na_2CO_3 , boiling with 1% Norit, filtering and pptg. as the Ca salt. T. S. C.

Labile prussic acid or isohydrocyanic acid. C. J. ENKLAAR. *Rec. trav. chim.* **44**, 889-90(1925).—(In German). In a previous paper (*C. A.* **18**, 1780) E. described the prepn. of a labile HCN from $AgCN + H_2S$ or better from KCN. The labile acid is characterized by a methylmercury deriv., m. 58°, that was previously described. It has now been prepd. from other CN compds. 0.3 g. $Na_4Fe(CN)_6$ in H_2O was treated drop by drop with concd. H_2SO_4 until the soln. smelled distinctly of HCN. The gas 1st evolved gives the compd. $MeHgCN$, m. 80-5°. After cooling CO was passed through the mixt. and on warming almost pure iso-HCN was evolved. Its $MeHgCN$ compd. m. 65-7°. 2 g. $Hg(CN)_2$ in 30 cc. H_2O was treated with insufficient H_2S and gave almost pure iso-HCN. $Pd(CN)_2$ in KCN soln. with a relatively small amt. of H_2S gave a mixt. of the 2 forms of HCN. $Cd(CN)_2$ and $Pb(CN)_2$ treated similarly gave only the stable HCN. Pure dry HCN contg. only stable HCN (by test) was distd. with H_2O and then appeared to contain 2.5% of the iso-HCN. E. J. WITZEMANN

The formation of symmetrical trimethylguanidine by amino displacement. MARTIN SCHENCK. *Z. physiol. Chem.* **150**, 121-32(1925).—*sym*-Trimethylguanidine (I) was prepd. from ICN, guanidine, mono- and dimethylguanidine, resp., by treatment with $MeNH_2$. In all these reactions it is believed that each successive methylation occurs through the intermediate formation of a methylated $C(NH_2)_4$ as an addn. product, followed by splitting out of NH_3 until the final product is I. With more highly methylated guanidines, the treatment with $MeNH_2$ displaces a Me_2NH and the product is I. Although I has not yet been found in nature the possibility still exists that it may be of biol. importance. For isolation the most suitable procedure would be the sepn. of the HI salt which is difficultly sol. in EtOH. A. W. DOX

Preparation of l-arabinose from mesquite gum. ERNEST ANDERSON AND LILA SANDS. *Ind. Eng. Chem.* **17**, 1257-8(1925).—l-Arabinose is readily prepd. by hydrolyzing mesquite gum for 3 hrs. at 80° with 6 times its wt. of 4% H_2SO_4 . After removing the acid with $Ba(OH)_2$, the neutral soln. is concd., the salts are pptd. with EtOH and the alc. soln. of the sugars is concd. and crystd. The m. p. is 140-55°. The yield of cryst. sugar is 27-36% on the gum, the greatest yield being obtained by recovering more arabinose by extn. of the salt ppt. with MeOH. It may be recrystd. from H_2O , dil. EtOH or glacial HOAc. Fermentation by yeast of the hydrolyzed gum did not increase the yield. C. C. DAVIS

Oxidation of d-glucose by air in calcium hydroxide solution. M. H. POWER AND F. W. UPSON. *J. Am. Chem. Soc.* **48**, 195-202(1926).—Of 100 g. of d-glucose dissolved in 10 l. of satd. $Ca(OH)_2$ soln., 95 g. was oxidized in 236 hrs. The products, on the basis of 100 g. oxidized, were 4.87 g. CO_2 , 23.1 g. volatile acids (as HCO_2H) and 84.9 g. non-volatile acids. The non-volatile acids gave 14.7 g. crude d-arabonic phenylhydrazide, 6 g. of high melting, EtOH-insol. brucine salt (brucine d-erythronate); 19.8 g. EtOH-sol. brucine salts (contg. some l-glyceric acid); 6.37 g. hydrates and 1.3 g. dried Ca glycolate and 4.1 g. $(CO_2H)_2$. The non-volatile fraction consisted largely of unidentified HO acids, the C_3 and C_4 acids occurring in such small amts. that their identification could not be sharp. The amts. of d-arabonic and glycolic acids actually present in the mix. were probably much greater than the reported values. d-Fructose under the same conditions gave 4.28 g. CO_2 and 9.1 g. $(CO_2H)_2$ per 100 g. C. J. WEST

Atmospheric oxidation. I. The oxidation of glucose and related substances in the presence of sodium ferropyrrophosphate. H. A. SPOEHR AND J. H. C. SMITH. *J. Am. Chem. Soc.* **48**, 236-48(1926); cf. *C. A.* **19**, 2676.—Na ferropyrrophosphate (I), which acts as a catalyst in the oxidation of carbohydrates and HO acids with air, is easily oxidized by atm. O. One mechanism by which the oxidation may be carried on is through the reversibility of the reaction: catalyst oxidized = catalyst reduced —e. A study of the electronic reversibility of the catalyst indicated unit electronic change, which agrees with the formula for I, $Na_2FeP_2O_7$ and for the ferri deriv., $NaFeP_2O_7$. It was not possible to obtain pure cryst. preps. of these compds. The catalyst is not

colloidal and gives none of the characteristic tests for Fe. Carbohydrates are oxidized whether the ferro or ferri compd. is initially present. HCO_2H is not oxidized with the ferri compd. Only such compds. as can reduce the ferri compd. are capable of the catalytic oxidation. Apparently this is associated with the degree of dissociation of the hexoses brought about by the phosphates. The rate of oxidation of a no. of org. acids was studied. The rates of reduction of the ferri compd. by glucose, fructose and mannitol also were studied. Low concns. of KCN (0.0025 *M*) accelerate the rate of oxidation; Pt has no effect. The rate of oxidation of glucose by air in this system is not influenced by insulin.

C. J. WEST

Relations between rotatory power and structure in the sugar group. XI. The related rotations of amylobiose, amylotriose and glucose. C. S. HUDSON, H. PRINGSHEIM AND J. LEBOWITZ. *J. Am. Chem. Soc.* **48**, 288–91 (1926); cf. *C. A.* **19**, 2476.—The application of the van't Hoff hypothesis of optical superposition to the structural formulas that have been proposed for amylobiose and amylotriose by Pringsheim leads to a simple numerical relation among the mol rotations of glucose, amylobiose and amylotriose. The rotation of α -amylobiose octaacetate is 122° (CHCl_3) and for α -amylotriose hendecaacetate, 128° (CHCl_3); both were amorphous. The above relation holds for the rotations of the sugars themselves and for those of their acetates. While this agreement with Pringsheim's structures does not necessarily prove their correctness, it supports the chem. evidence adduced by P.

C. J. WEST

This sugar from yeast. P. A. LEVENE AND H. SOBOTKA. *J. Biol. Chem.* **65**, 551–4 (1925).—The sugar of the adenine nucleoside discovered in "zymin" by Mandel and Dunham (*C. A.* **6**, 2241), considered to be a new ketohexose by L. (*C. A.* **18**, 2500), and shown to contain S by Suzuki, Odake and Mori (*C. A.* **19**, 1867), has now been studied further. The sirupy sugar (I) showed $[\alpha]_D^{25} +41.9^\circ$ in MeOH; SMe, 24.3%, calcd. for $\text{C}_6\text{H}_{12}\text{O}_4\text{S}$, 26.1%, the detn. being made according to Kirpal and Buln (*C. A.* **8**, 2163). *Tri. Ac. deriv.* (II), from Ac_2O and $\text{C}_6\text{H}_5\text{N}$, $b_D^{25} +170^\circ$. The previously described *p*-bromophenylosazone (I, *loc. cit.*) is still formed after exposure of I to excess Br for 96 hrs., excluding the aldehydic structure given by S, O. and M. in their 4 alternative formulas, also the presence of $-\text{SH}$. This, together with the formation of II, excludes 3 of the 4 on other grounds. The choice is considered restricted to $\text{HOCH}_2\text{C}(\text{OH})\text{CHSMe}.\text{CHOH}.\text{CH}_2\text{O}$ or $\text{HOCH}_2\text{C}(\text{OH})\text{CHOMe}.\text{CHOH}.\text{CH}_2\text{S}$, with

the substituent group possibly on carbon 1 instead

M. HEIDELBERGER

Formation of *d*-sorbose and *d*-gulose by oxidation of *d*-sorbitol with bromine water. H. W. TALEN. *Rec. trav. chim.* **44**, 891–3 (1925).—(In English.) Votoček and Lukeš (*C. A.* **19**, 2933) oxidized *d*-sorbitol to a mixt. of 4 isomeric hexoses, which were converted into the 2 possible phenylosazones and sepd. by their differential soly. in Me_2CO . T. has repeated the oxidation and removed the *d*-glucose and *d*-fructose by alc. fermentation of the mixt. The *d*-gulose and *d*-sorbose that remain unfermented were converted into the phenylosazone as described by V. and L. and identified as *d*-gulose (and *d*-sorbose) phenylosazone.

E. J. WITZEMANN

The absorbing power of nitrocellulose for gases. DOMENICO COSTA. *Gazz. chim. ital.* **55**, 540–8 (1925).—Recently C. showed that the absorbing power of starch for some gases (*C. A.* **18**, 3175) is much greater than that of cellulose (Oddo, *C. A.* **14**, 1529) under the same conditions. A sample of nitrocellulose (I) contg. 12.95% N and corresponding to a decanitrocellulose was used after drying 24 hrs. at 50° and 1 hr. at 90° . The volumetric app. of Oddo (*l. c.*) was used. Under the action of dry NH_3 I first becomes yellow and then darkens, becoming brown-black with the evolution of heat. The mol. of I is demolished without, however, giving rise to H_2O or gaseous products. From the results it is concluded that the nitric esters of cellulose, $\text{C}_{24}\text{H}_{18}\text{O}_8(\text{ONO}_2)_{10}(\text{OH})_2$, fix NH_3 at first in proportions corresponding to 1 mol. of NH_3 for each ONO_2 group present. The NH_3 absorbed combines with the ONO_2 groups, forming the true salt of NH_4 with consequent denitration and dehydrogenation of I and decompn. of the cellulose complex. The NH_4NO_3 thus formed absorbs more NH_3 in the proportion of 2 mols. for 1 of NH_4NO_3 . Dry HCl displaces the ONO_2 groups in I completely and gives products free from N, sol. in H_2O , that reduce Fehling soln. and are optically active. This reaction and its products are to be described in another paper. 100 g. I absorbs 12.67 g. SO_2 in 144 hrs. 100 g. I absorbs 1.0016 g. CO_2 in 96 hrs. H_2 and O_2 are not adsorbed by I in appreciable proportions.

E. J. WITZEMANN

Naphthenic acids. VI. Naphthenic acids derived from Nishiyama petroleum. YOSHIO TANAKA AND SHOICHIRO NAGAI. *J. Faculty Eng. Tokyo Imp. Univ.* **16**, 171–81 (1925); cf. *C. A.* **19**, 1136.—The crude petroleum acids employed were obtained by acidifying the waste lyes produced in the refining of kerosene distillate (41.5°Bé.)

and gas oil or "neutral oil" distillate (33.2° Bé.) of Nishiyama (Niigata prefecture) origin, in yields of 0.02 and 0.15% by vol. of these distillates, resp. The proximate analysis of the crude acids, the crude naphthenic acids, the pure mixed acids and distn. products are given. These acids, as compared with those of Kurokawa origin, show about the same distn. range and the neutralization values of the corresponding fractions are also very similar but the d. of the fractions of the former are much lower than those of the latter, showing that the acids from these different sources contain different isomers. After 25 systematic fractional distns of the Me esters there were obtained 4 main fractions. There are given for the acids b_{8-9-10} , d_4^{15} , d_4^{20} , n_{15}^{15} , n_{20}^{20} , neutralization value, M_D ; for the esters b_{8-9-10} , $b_{76.0}$, d_4^{15} , n_{15}^{15} , sapon. value, M_P : *Dodecanaphthenic acid*, 168–70°, 0.9712, 0.9681, 1.4697, 1.4678, 279.4, 56.92; *Me ester*, 127–9°, 265–6° 0.9412, 1.4579, 265.9, 61.19, *tridecanaphthenic acid*, 177–9°, 0.9736, 0.9704, 1.4727, 1.4708, 267.3, 61.13; *Me ester*, 136–8° 277 8°, 0.9443, 1.4612, 244.3, 56.30; *tetradecanaphthenic acid*, 186 8°, 0.9762, 0.9732, 1.4759, 1.4740, 248.6, 65.49; *Me ester*, 145.5–7.5°, 289–90°, 0.9191, 1.4647, 236.5, 69.92; *pentadecanaphthenic acid*, 194.7°, 0.9776, 0.9744, 1.4784, 1.4765, 232, 69.63; *Me ester*, 155 7°, 300–1°, 0.9501, 1.4672, 221, 74.54. The same main constituents were isolated from both naphthenic acids derived from the 2 distillates.

C. J. WEST

The doctrine of intramolecular oppositions and the directing of substituents in benzene. II. D. VORLANDER. *Ber.* 58B, 1893–914(1925); cf. *C. A.* 13, 2348.—

Since the positive N in the quaternary ammonium residue $\text{--NMe}_3^+\text{X}^-$ on C_6H_6 directs a 2nd substituent on nitration or bromination to the *m*-position, such residues as --NO_2^+ , $\text{--CO}_2\text{H}^+$, --CO^+ , $\text{--SO}_3\text{H}^+$, which have erroneously been considered as negative, are really positive with respect to their point of union and, like ammonium, act on the benzene C through a positive element (N, C, S). In the present paper are presented further new exptl. data on the behavior of positively and negatively substituted C_6H_6 derivs. PhIO and PhIO_2 are reduced by concd. HNO_3 to PhI with formation of *p*- and *o*- $\text{O}_2\text{N--C}_6\text{H}_4\text{I}$. If the formation of the reducing HNO_2 is prevented by the addn. of urea nitrate, PhIO_2 is difficultly attacked by concd. HNO_3 , indicating that the I of the IO_2 group is positively attached to the C_6H_6 . Ph_2INO_3 gives (*m*- $\text{O}_2\text{NC}_6\text{H}_4$) $_2\text{INO}_3$ (I), identical with the product obtained from *m*- $\text{O}_2\text{NC}_6\text{H}_4\text{IO}_2$ and *m*- $\text{O}_2\text{NC}_6\text{H}_4\text{IO}$ with Ag_2O and decompd by boiling dil. alkalis into *m*- $\text{O}_2\text{NC}_6\text{H}_4\text{OH}$ and *m*- $\text{O}_2\text{NC}_6\text{H}_4\text{I}$ with possibly traces of *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{OH}$ but no *o*- $\text{O}_2\text{NC}_6\text{H}_4\text{OH}$ at all. The plurivalent I in diphenyliodonium salts is in its whole atomistic structure positive as well towards the anion as towards both C_6H_6 nuclei. Nitration of PhPh_4 has hitherto given no useful results; there is formed a peculiar cherry-red soln in the $\text{KNO}_3\text{--H}_2\text{SO}_4$ mixt and pouring into H_2O gives besides much PhNO_2 (also some *m*- $\text{C}_6\text{H}_4(\text{NO}_2)_2$) a brown flocculent substance which deflagrates on heating. $\text{Ph}_2\text{Ph}(\text{NO}_3)_2$, however, yields the well-crystd. colorless (*m*- $\text{O}_2\text{NC}_6\text{H}_4$) $_2\text{Ph}(\text{NO}_3)_2$ (II), which explodes on heating and with Br at 100° gives *m*- $\text{O}_2\text{NC}_6\text{H}_4\text{Br}$ and PhBr_2 . The *Pb*, like the I in the iodonium salts, has an equally positive action on both *Ph* residues. Likewise, $\text{Ph}_3\text{Bi}(\text{NO}_3)_2$ yields a cryst. tri-*m*- NO_2 (III). On the other hand, SiPh_4 and SnPh_4 yield chiefly *p*-compds., which, unfortunately, are not as homogeneous and well-crystd. as the *Pb* and *Bi* derivs. The products obtained from Ph_3COH show such peculiar behavior that it is doubtful whether they are normal nitration products; they are amorphous brownish substances which cannot be made to cryst. under any conditions and, after exhaustive treatment with HNO_3 , have approx. the N content of a ($\text{O}_2\text{NC}_6\text{H}_4$) $_3\text{COH}$; all attempts to det. the position of the NO_2 groups have thus far failed. Ph_3CCN gives an amorphous tri-*p*- NO_2 deriv. (IV), lac-like or glassy when cold; the *p*-position of the NO_2 groups is established by conversion into parafuchsin and by the identity of the tri- NH_2 (V) deriv. with Muller's hydrocyanopararosaniline (*Z. Chem.* 2, 2(1866)). The CN group in Ph_3CCN , not present as an anion, therefore imparts no positive or cationic properties to the carbinol C atom. The lac-like consistency of Ph_3C derivs. is due to their dissymmetry; such substances remain permanently in a supercooled amorphous state and are at the same time monomol. The solns. of the ($\text{O}_2\text{NC}_6\text{H}_4$) $_3\text{CCN}$ are hardly colloidal and produce the calcd. raising of the b. p. From all the results hitherto reported, the following law can be derived: An element combined with 2, 3 and 4 C_6H_6 nuclei directs new substituents in these C_6H_6 nuclei equally positively or equally negatively. The pyridinium N in phenylpyridinium salts directs an entering NO_2 group to the *m*-position of the *Ph* residue; the structure of the *m*-nitrophenylpyridinium nitrate (VI) obtained was established by

synthesizing the 3 isomers from C_6H_5N , $BrCN$ and the three $O_2NC_6H_4NH_2$. The behavior of *N*-phenylpyridinium bromide on bromination also points to the strong positive action of the N on the Ph. *N*-Phenylpyridone (VII), in which, according to the structure assigned to it, the N might act as an amine (formation of *o*- and *p*-compds.) or an ammonium deriv. (formation of *m*-derivs.) gives a well-crystd. mono- NO_2 deriv. whose structure could not be detd. by cleavage; it is not identical with that synthesized from chelidonic acid and *m*- $O_2NC_6H_4NH_2$ and as the corresponding *o*- and *p*-compds. could not be satisfactorily synthesized in the same way (probably on account of the too feebly aminic properties of the corresponding $O_2NC_6H_4NH_2$), the product of nitration was reduced to the amine, diazotized and coupled with $PhOH$; the resulting *hydroxyazo dye* (VIII) yielded a monotropic cryst.-liquid acetate and an enantiotropic cryst.-liquid benzoate, thus indicating that the NO_2 group is in the *p*-position, a conclusion confirmed by conversion of the NH_2 deriv. into *chlorophenylpyridone*, m. 105° , and identification of the latter with the product obtained from chelidonic acid and *p*- $ClC_6H_4NH_2$. VII, therefore, in spite of the presence of an excess of concd. HNO_3 , is nitrated not as an NH_4 salt but as free pyridone, presumably in the form of an amine in which the N is negative to the Ph. Its great resistance towards HNO_3 shows, however, that in the soln. it is present chiefly as an NH_4 salt. The valence angle on the N is apparently quite different in VII and *N*-phenylpyridinium, for the *p*- NO_2 compds. of the latter yield no cryst.-liquid derivs. In methylpyridinium methosulfate the C_6H_5N nucleus remained unattacked in all attempts at bromination or nitration under the most varied conditions at 100° . The tertiary *p*- $PhC_6H_4NMe_2$ reacts in the *p'*-position with neither HNO_2 nor aryldiazonium salts; the quaternary *p*- $PhC_6H_4NMe_3NO_3$ takes up on nitration a NO_2 group in the *p'*-position, like *p*- $PhC_6H_4NO_2$, i. e., NO_2 has the same influence as NMe_3 . *p*-Amino-*p'*-dimethylaminobiphenyl (unsym-dimethylbenzidine) (IX) gives no methylene blue reaction with $FeCl_3 \cdot H_2S$; the orange-brownish *p*-benzenazo-*p'*-amino-biphenyl (X) gives with concd. H_2SO_4 a red soln., to be sure, but is decolorized by dil. acids (the mono-HCl salt is pale yellow), while the orange-yellow *p*-biphenylazo-*N*-dimethylaniline (XI) normally forms a dark violet mono-HCl salt and a red-violet soln. with concd. H_2SO_4 . Only in respect to the decolorization of adducts is there an analogy between Ph_3 and simple C_6H_6 derivs., insofar as the orange red *p*,*p'*- $O_2NC_6H_4C_6H_4NH_2$ or *p*,*p'*- $O_2NC_6H_4C_6H_4NMe_2$ are decolorized by acids just like *p*- $O_2NC_6H_4NH_2$, *p*- $O_2NC_6H_4NMe_2$, *p*- $O_2NC_6H_4NHCH_2Ph$, etc. *Bis*-*m*-nitrodiphenylodinium nitrate (I) (10–1 g. from 10 g. Ph_2INO_3 in 45 g. HNO_3 (d. 1.52) and 40 g. concd. H_2SO_4 kept 15 min. at $15\text{--}20^\circ$), m. 194° ; iodide, yellowish, m. $142\text{--}4^\circ$ with formation of *m*- $O_2NC_6H_4I$, becomes darker yellow on standing in the light and then m. 130° ; chloride, m. 209° ; perchlorate, m. 188° , explodes over a free flame; picrate, yellow, m. about 191° . *Bis*-*m*-nitrophenyllead dinitrate (II) (3.5 g. crude g. crystd. product from 4 g. $Ph_3Pb(NO_3)_3$ heated 3–4 hrs. at 100° with HNO_3 (d. 1.51)), explodes about 210° . *Tris*-*m*-nitrophenylbismuth dinitrate (III) (1.5 g. from 2.5 g. triphenylbismuth dinitrate, deflagrates about 130° (obtained by repeatedly evap. the dibromide with HNO_3 (d. 1.3) on the H_2O bath), allowed to stand 20–4 hrs. in fuming HNO_3 (d. 1.52)), yellowish white, deflagrates about 145° , decompd. by boiling H_2O or hot alc., gives *m*- $O_2NC_6H_4Br$ with Br water after 3 days at room temp. or 2–3 hrs. at 100° . $Si(C_6H_4NO_2)_4$ (Polis, Ber. 19, 1016(1886)) with Br water and a few drops of Br heated 30–40 hrs. at 100° gives *p*- $O_2NC_6H_4Br$. Likewise, tetranitrotetraphenyllin, from $SnPh_4$ in fuming HNO_3 -concd. H_2SO_4 at $\sim 5^\circ$ to 0° , flocculent gray or brown ppt., deflagrates above 350° , gives *p*- $O_2NC_6H_4Br$ with Br water and Br at 100° . *Tris*-*p*-nitrophenylacetoneitrile (IV), from Ph_3CCN and fuming HNO_3 at 15° , m. $210\text{--}20^\circ$, mol. wt. in boiling C_6H_6 358–64, shows no fluorescence in Me_2CO or C_6H_6 and the solns. exhibit no colloidal properties under the ultramicroscope; tri- NH_2 deriv. (V), from IV with $SnCl_2 \cdot HCl$ or alc. $(NH_4)_2S$, gradually becomes brownish on heating, reddish at about 250° , sinters 265° , m. $280\text{--}90^\circ$, shows in Me_2CO and C_6H_6 under the ultramicroscope a fluorescence band, forms a strongly colloidal soln. in aq. HCl , is converted back into Ph_3CCN by diazotization and reduction with Cu ; its Ac deriv. seps. from the colloidal solns., which show blue fluorescence, as a hard transparent lac softening at $70\text{--}130^\circ$; the yellow compd. of V with anisaldehyde can likewise not be crystd. and the product of the decompn. of its diazonium sulfate (presumably $(p\text{-}HOC_6H_4)_3CCN$) is amorphous and sol. in alkalis; coupling of the diazonium chloride with $PhOH$ in $NaOH$ yields a rust-brown flocculent hydroxyazo compd., probably $(HOC_6H_4N_2C_6H_4)_3CCN$, softens about 170° , forms a viscous liquid around 210° , gives a strongly colloidal red-brown soln. in Me_2CO . The solid HCl salt of V heated to $170\text{--}220^\circ$ gives parafuchsin (not a trace is formed by boiling an HCl soln.) with evolution of HCN ; the reaction is not complete until after 16 hrs. at about 200° ; V. believes that it is only the HCl salt which undergoes decompn. while

the free V resulting from hydrolysis is not attacked. *N*-Phenylpyridinium nitrate, from the chloride repeatedly evapd. with HNO_3 (d. 1.3), yellowish white, m. 126° , is quickly decompd. by alkalis; 5 g. heated 6–12 hrs. at 100° with fuming HCl gives 3.5 g. crude or 1.8 g. recrystd. VI, yellowish or nearly colorless, turns brown and sinters about 195° , m. $204-8^\circ$, decomp. above the m. p., is somewhat more stable towards cold alkalis than the original $\text{C}_6\text{H}_5\text{NPhNO}_3$; chloride- HgCl_2 compd., m. $165-8^\circ$; tribromide, $\text{C}_6\text{H}_5\text{N}(\text{C}_6\text{H}_4\text{NO}_2)_2\text{Br}_3$, orange-yellow, m. about 117° (the non-nitrated perbromide, m. $111-3^\circ$); amino bromide perbromide, brown-yellow, m. $172-5^\circ$. *p*-Isomer of VI (15 g. from 55 g. *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{NH}_2$ with $\text{C}_6\text{H}_5\text{N}$ and BrCN), slightly yellowish, m. $174-7^\circ$; chloride; perbromide, m. about 165° ; picrate, yellow, m. 117° ; perchlorate, m. about 176° (the salts are at once colored dark violet-brown or black by alkalis); amino nitrate, begins to m. 200° , decomp. 210° , sol. in H_2O with yellow color, at once colored yellow to brown by alkalis, followed by sepn. of black flocks which are turned red by HCl ; picrate, m. $158-61^\circ$; chloride- HCl , becomes discolored and decomp. above 190° , sol. in H_2O with yellow color and completely decolorized by dil. HCl , gives a violet soln. with Fe^{+++} salts, green, then blue, with H_2S and FeCl_3 , yields red and brown azo dyes when diazotized and coupled with 2 naphthol, PhOH or PhNMe_2 . *p*-Ethoxyphenylpyridinium salts, prepd. by the methods of Zincke (*Ann.* 333, 330(1901)) and König (*J. prakt. Chem.* 69, 130(1904)): HgCl_2 ; chloride, needles with 1 or 0.5 H_2O from $\text{EtOH-Et}_2\text{O}$, m. 118° ; perchlorate, m. 131° ; picrate, yellow, m. 139° ; bromide (H_2O). *o*-Isomer of VI, yellowish, m. $182-6^\circ$ (decompn.); bromide perbromide, m. $90-3^\circ$; chloride- HgCl_2 compd., yellowish, m. about 190° . VII ($2\text{H}_2\text{O}$), m. 101° or, anhyd., 127° , forms with acids salts quite stable towards H_2O and solvents; chloride (H_2O), m. about 192° ; the yellowish nitrate, m. 88° , and the perchlorate, m. 164° , also seem to contain H_2O of crystn.; picrate, yellow, m. 193° ; HgCl_2 compd., m. about 118° . VII seps unchanged from boiling KOH . Refluxed 2–3 hrs. or evapd. to dryness with 50 cc. HNO_3 (d. 1.51), 10 g. VII gives 12.7 g. *p*- NO_2 nitrate, yellow needles with H_2O , m. 146° ; perchlorate, m. about 245° ; picrate, yellow, m. about $190-2^\circ$; free *p*-nitrophenylpyridone, faintly yellowish needles with H_2O , m. 202° ; *p*- NH_2 deriv. (3.5 g. from 6 g. of the NO_2 compd. with $\text{SnCl}_2\text{-AcOH}$), m. $260-70^\circ$ (decompn.), yields an azo dye with 2-naphthol. VIII, brown; acetate, orange, m. about 250° (decompn.); benzoate, orange-yellow, 1st m. p. about 263° , 2nd about 250° . *p*-Hydroxyphenylpyridone, from the NH_2 compd. by diazotization and decompn. in dil. HCl , lemon-yellow, decomp. above 200° , sol. in alkalis with yellow color, reprecip. by acids, gives a brown color with FeCl_3 ; owing to the formation of tars it could not be methylated or ethylated; the *Et* ether (XII), obtained in about 20% yield from chelidonic acid and *p*- $\text{EtOC}_6\text{H}_4\text{NH}_2$ at $130-70^\circ$, m. $154-6^\circ$, forms a perchlorate, m. 195° . Chelidonic acid (4.6 g.) refluxed 2 hrs. with 2 mols. *m*- $\text{O}_2\text{NC}_6\text{H}_4\text{NH}_2$ in H_2O gives chelidonic *m*-nitrophenylamide which at $160-80^\circ$ yields 1.2 g. *m*-nitrophenylpyridone, yellowish, m. about 210° ; perchlorate, m. around 176° ; picrate, yellow, m. about 175° . *N*-Phenyl- γ -chloropyridinium chloride (2.1 g. from 3 g. VII with SOCl_2 at $130-40^\circ$), crystals with $2\text{H}_2\text{O}$, sinters 83° , m. about 116° , soon forms a brown resin with cold NaOH ; HgCl_2 compd., m. about 180° ; perchlorate, m. 210° ; picrate, yellow, m. $155-8^\circ$; tribromide, yellow, m. 137° . Phenylpyridinium salts exert on frogs the characteristic curare action (paralysis of the motor nerves and death owing to stoppage of the respiration); VII was too little sol. to permit of testing its pharmacol. action but XII in 1% soln. in 0.01 and 0.02 g. doses produces complete paralysis in 15 min., without any previous observable stimulation, *i. e.*, it does not possess the specific curare action of quaternary NH_4 compds. Biphenyl-*p*-trimethylammonium bromide, obtained almost quant. from *p*- $\text{PhC}_6\text{H}_4\text{NH}_2$ in H_2O suspension on the H_2O bath turbined with excess of Me_3SO_4 and K_2CO_3 until dissolved, acidified with AcOH and treated cold with KBr , sinters 210° , m. 222° (decompn.), is neither nitrated nor nitrosated in acid soln. by HNO_3 ; tribromide, golden yellow, m. about 188° (decompn.), converted into the bromide by long boiling with H_2O ; iodide, sinters 208° , m. about 220° (decompn.); picrate, yellow, m. about 310° (decompn.); perchlorate, decomp. above 300° , deflagrates on rapid heating; nitrate, sinters 230° , m. about 255° (decompn.) gives with fuming HNO_3 below 70° about 20% of the *p*-nitro nitrate, sinters and reddens 212° , m. about 235° (decompn.); tribromide, yellow, m. about 198° (decompn.); bromide, sinters about 165° , m. around 243° (decompn.); iodide, m. about 246° (decompn.), becomes yellow on drying; picrate, yellow, decomp. about 200° (weak deflagration). The nitro bromide (6 g.) heated to $240-60^\circ$ gives 0.5 g. *p*-nitro-*p*-dimethylaminobiphenyl (XIII), yellow-red, m. about 244° , sol. in dil. mineral acids almost without color, identical with the product obtained by methylating *p*'- $\text{O}_2\text{NC}_6\text{H}_4\text{C}_6\text{H}_4\text{NH}_2$ (XIV) with alk. Me_3SO_4 ; it slowly reacts with NaNO_2 in acid soln. with formation of a dark orange di- NO_2 deriv. (presumably *p*',*m*,*p*- $\text{O}_2\text{NC}_6\text{H}_4\text{C}_6\text{H}_3(\text{NO}_2)_2\text{NMe}_2$), m. 134° .

IX (0.2 g. from 3 g. of the NO_2 compd. with SnCl_2 -alc. HCl), m. about 146° , sol. in dil. HCl or H_2SO_4 , gradually becomes green and brown in the air or with K_2CrO_4 and FeCl_3 ; *HCl* salt, flocculent ppt. becoming gelatinous; *benzylidene deriv.*, $\text{PhCH}:\text{NC}_6\text{H}_4\text{C}_6\text{H}_4\text{NMe}_2$, yellow leaflets, enantiotropic cryst.-liquid, 1st m. p. 192° , 2nd 183° ; *p*-toluylidene deriv., yellow, m. ps. 248° , 218° ; *p*-anisylidene deriv., orange, m. ps. $> 270^\circ$, 208° . *Tetramethyl-p,p'*-diaminoazobiphenyl, from **XIII** with Zn dust and hot alc. KOH, followed by oxidation of the hydrazo compd. with air, red, m. about 315° , gives with concd. H_2SO_4 a red, with fuming HCl a dark brown, with dil acids a yellow-brown color; *HCl* salt, brownish. *p*-Nitrobiphenyl-*p'*-azobenzene (from 2 g. **XIV** and PhNO in AcOH), light brown, m. 180° , indistinctly cryst.-liquid, little changed by dil. acids, forms a red soln. in concd. H_2SO_4 , converted in hot alc. suspension by concd. NH_4OH and H_2S and subsequent treatment with air into **X**, m. around 178° (decompn.), not cryst.-liquid on the 1st fusion but the supercooled melt on somewhat higher heating becomes enantiotropically cryst. liquid, turning red; it forms a faintly yellow sulfate with dil. H_2SO_4 ; *benzylidene deriv.*, orange, enantiotropic cryst.-liquid, m. ps. 188° , 171° (decompn.); *p*-anisylidene deriv., orange-red, enantiotropic cryst.-liquid, m. ps. $> 192^\circ$, 173° (decompn.). **XI**, from *p*- $\text{PhC}_6\text{H}_4\text{NH}_2$ by diazotization and copulation with PhNH_2 , sinters 195° , m. 208° , is not cryst.-liquid. *p*-Biphenylhydroxylamine, m. $132-4^\circ$, soon becomes yellow in the air and changes into $(p\text{-PhC}_6\text{H}_4\text{N})_2$, reduces Fehling soln. *p*-Nitrosobiphenyl, obtained in very small amt, together with $(\text{PhC}_6\text{H}_4)_2\text{N}_2\text{O}$, from the $\text{PhC}_6\text{H}_4\text{NHOH}$ with $\text{K}_2\text{Cr}_2\text{O}_7$ in cold 10% H_2SO_4 , yellow-green, m. 84° to a green liquid, has a quinone-like odor, dissolves in alc with green-yellow color. $(p\text{-PhC}_6\text{H}_4\text{N})_2$, from $\text{PhC}_6\text{H}_4\text{NO}$ and $\text{H}_2\text{NC}_6\text{H}_4\text{Ph}$ in boiling alc., orange-red, m. 250° , monotropic cryst.-liquid. $(p\text{-PhC}_6\text{H}_4)_2\text{N}_2\text{O}$, m. 206° , monotropic cryst.-liquid. *Diazoaminobiphenyl*, from $\text{PhC}_6\text{H}_4\text{N}_2\text{Cl}$ and $\text{H}_2\text{NC}_6\text{H}_4\text{Ph}$ in AcOH - NaOAc , yellow, m. 147° , non-cryst. liquid, insol. in dil. acids and unchanged in color. C. A. R.

Aldehydes and ethylene oxide in the Friedel-Crafts synthesis. ALFRED SCHAAER-SCHMIDT, L. HERMANN and B. SZEMZO. *Ber.* **58B**, 1914-6(1925).—From 53 g. BzH in cold C_6H_6 treated in the course of 45 min. with 150 g. AlCl_3 and then heated 2 hrs. at 40° and 3 hrs. at 60° with frequent shaking were obtained CH_2Ph_2 , 21% CHPh_3 and 30% anthracene (**I**). FeCl_3 instead of AlCl_3 gave 30% CHPh_3 and 6% **I**. *iso*- BuCHO with AlCl_3 gave an oil, b. $296-9^\circ$, whose yellow color, d. and mol. refraction indicated with certainty the presence of $\text{Me}_2\text{C}(\text{H})\text{C}(\text{H})\text{CPh}_2$, although the satd compd., b. 297° , was also without doubt present. Ethylene oxide vapor, mixed with HCl gas, passed into $\text{AlCl}_3\text{-C}_6\text{H}_6$ gave 1% $\text{PhCH}_2\text{CH}_2\text{OH}$ and 40% $(\text{PhCH}_2)_2$. C. A. R.

Action of bromine upon caffeine (and) method of preparation of bromotheophylline. Y. YOSHITOMI. *J. Pharm. Soc. Japan No.* **524**, 884-8(1925).—The method of chlorination of caffeine was applied to bromocaffeine. Neither Fischer and Ach's 7,8-dichlorocaffeine synthesis under ordinary pressures, with various catalysts nor F. and A.'s method in the sealed tube (*Ber.* **39**, 429) gave 7,8-dibromocaffeine. The F. and A. 3,8-dichlorocaffeine synthesis (*Ber.* **39**, 426) in the sealed tube also failed to give 3,8-dibromocaffeine or bromoparaxanthine from bromocaffeine. Every indication of reaction between Br and bromocaffeine always resulted in the rupture of the purine nucleus. The prepn. of bromotheophylline is given as follows: 10 g. of theophylline, 80 g. PhNO_2 , and 20 g. dry CCl_4 are stirred and 10 g. dried Br dissolved in PhNO_2 is added drop by drop. The mixt. is then heated for 2 hrs. at 110° . When the excess Br and HBr are removed by air and H_2O , and the reagents by steam, white crystals, m. 322° , and analyzing for bromotheophylline are formed. S. T.

Some homologs of true phenylpropine. L. BERT, P. CH. DORIER and R. LAMY. *Compt. rend.* **181**, 555-6(1925).— $\text{CH}_2\text{C}(\text{H})\text{CH}:\text{CHCl}$ and RMgX forms $\text{RCH}_2\text{CH}:\text{CHCl}$ (cf. C. A. **19**, 2644), which on treatment with NaNH_2 gives $\text{RCH}_2\text{C}:\text{CNa}$, the latter on acidification then forming $\text{RCH}_2\text{C}:\text{CH}$. Based on these reactions and by the method of Bourgel (C. A. **19**, 3476) improved by mech. agitation at $110-20^\circ$, the following previously unknown compds. were prepd. The data give the b. p., d_4^{20} , d_4^{25} , n_D^{20} , $[(n^2-1)M]/[(n^2+2)d]$ and theoretical R_m resp.: *phenylbutine*, 83, 0.928, 0.918, 1.518, 42.91, 42.78; *o*-methylphenylpropine, 80, 0.951, 0.940, 1.532, 42.85, 42.78; *p*-methylphenylpropine, 83, 0.958, 0.947, 1.533, 42.48, 42.78; *m*-xylol-4-propine, 95, 0.952, 0.941, 1.534, 47.56, 47.40; *p*-xylol-2-propine, 98, 0.951, 0.939, 1.531, 47.44, 47.40; *p*-isopropylphenylpropine, 101, 0.933, 0.924, 1.523, 52.23, 52.02; *carvacrylpropine*, 115, 0.929, 0.919, 1.525, 57.35, 56.63. The yields were about 75%. They were all colorless liquids, turning yellow in time, with a tendency to foam and with a penetrating odor. With alc. AgNO_3 they formed white ppts. and with $\text{NH}_3\text{-CuCl}$, yellow solids which were decompd. by cold concd. HCl . C. C. DAVIS.

The decomposition constants of organic complexes. H. LEY, R. GRAU and W.

EMMERICH. *Ber.* 58B, 1765-75(1925); cf. *C. A.* 15, 2428.—In the complex compds. of $C_6H_5(NO_2)_3$ (I) and $PhNMe_2$ (II) or its homologs the introduction of Me or other groups into the *o*-positions produces anomalous color changes (see abstr. quoted). In a dissociating solvent, $CHCl_3$, the same is observed; the soln. of the *p*- $MeC_6H_4NMe_2$ (III) complex is reddish violet, that of the *o*-isomer (IV) complex is yellow. To det. quant. the colors of the complexes their decompn. const., k , in soln. must be known. If in a soln. of the complex, A_nN_m , C_A , C_N , C_{ANm} , are the concns., in mols./l. of amine, nitro compd. and undecompd. complex, resp., $k = (C_N^m C_A^n) / C_{ANm}$. Methods for detg. k were investigated: (1) by observing the changes in soly. in a heterogeneous system in which I constituted the solid phase and $CHCl_3$ solns. of II, III or IV the liquid phase. It was assumed throughout that $n = m = 1$. $C_N =$ soly. of I in $CHCl_3$, $C'_N =$ soly. of I in $CHCl_3$ soln. of amine concn. C'_A . Then $k = (C_N C'_A) / (C'_N - C_N) - C_N$. Expts. made at 17.5° . C_N 0.2877. For complexes I-II and I-III the values of k were of the same order, 0.69 and 0.57, resp. With I-IV $C'_N - C_N$ was negative so it was impossible to calc. k . Similar effects were observed with 1,3,4- and 1,3,2-dimethylxylinines. All are compds. whose absorption spectra are abnormal. It is concluded that in the case of *o*-compds there is both a soly. effect and a very small complex formation. This anomaly of the *o*-substitution does not occur with primary amines. (2) *Photometric detns.* showed that Beer's law did not apply to solns. of the complexes, thus confirming the supposition of decompn. in soln. The very small absorption of the decompn. products made it possible to take ϵ , the decadic extinction coeff., as a measure of the concn. of undecompd. complex (C_{AN}). $C_{AN} = \epsilon_1(1-x)/\epsilon_2 = \epsilon_1\gamma$, where x is the degree of decompn. of a standard soln. of equal concns of amine and nitro compd., calcd with the aid of the law of mass action from the ratio of ϵ ϵ' , the extinction coeff. of the standard soln. when the amine concn. is increased n -fold and ϵ_1 is the extinction of the unknown at diln. v . Hence $k = [(C_A - \epsilon_1\gamma)(C_N - \epsilon_1\gamma)] / \epsilon_1\gamma$. For the I-II complex $k = 0.55$, for the I-IV complex k varies from 3.03 to 3.82. The authors consider this value too low and indicate factors which may vitiate the results. The photometric measurements are interpreted as confirming the assumption that the complexes are built of equal nos. of mols. of nitro compd. and amine. (3) *Observations of the raising of the b. p. of $CHCl_3$* by the complexes give for I-II $k = 0.2$, I-III $k = 0.28$, and I-IV $k = 0.3$. The authors conclude after discussion that this method is no good. Taking for the decompn. const. of I-II and I-III 0.7 and 0.6, resp., the max. mol. extinction of the undissociated complexes (at $1/\lambda = 2050$) is 1050 and 1300. The value for I-IV can only be obtained with much uncertainty. Curves giving the relation of the mol. extinction to $1/\lambda$ follow the usual course through a max. with I-II and I-III but there is no max. in the curve for I-IV. Thus in these complexes there is very considerable absorption and it is concluded that the electrons in the chromophore group are very much loosened. What the chromophore is, cannot be exactly stated but it is supposed that there is an equalization of affinity between the nitro groups and the double bonds (*Lückenbindungen*) of the C_6H_6 nucleus of the amine component, which results in a diminished satn. of some other atom, perhaps the N of the NO_2 groups. The peculiar behavior of the *o*-Me compds. in comparison with the others is not due to their basic characters. The dissociation const. of 4 amines were detd. from data on hydrolysis of HCl salts and acetates and new cond. data. $PhNMe_2$, $k_b = 1.47 \times 10^{-9}$, $PhNH_2$, $k_b = 2.70 \times 10^{-8}$, *o*- $MeC_6H_4NMe_2$, $k_b = 1.08 \times 10^{-8}$, *p*-isomer, $k_b = 4.19 \times 10^{-9}$. The NMe_2 group does not take part directly in complex formation, but only insofar as its presence loosens the bonds in the C_6H_6 nucleus and hence permits stronger union with the nitro compd. Me and other space-filling groups tend to reduce this loosening of the C_6H_6 bonds.

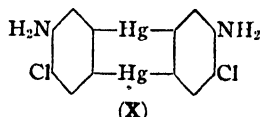

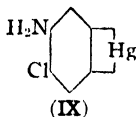

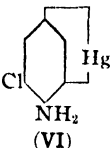

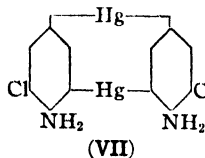

R. E. GIBSON

The action of the Grignard reagent on amino acids. VI. *Fusion cleavage of amino alcohols.* FRITZ BETTZICHE AND ALFRED EHRLICH. *Z. physiol. Chem.* 150, 191-6(1925); cf. *C. A.* 19, 3254.—The amino tert. alcs., prepd. by the Grignard reagent, undergo cleavage into ketone and amine when heated in a sealed tube with H_2O at comparatively high temps. (120-200°). $PhCH(NH_2)CPh_2OH$ gave $PhCH_2NH_2$ and $BzPh$; $PhCH(NH_2)C(CH_2Ph)_2OH$ gave $(PhCH_2)_2CO$ and $PhCH_2NH_2$; $H_2NCH_2CPh_2OH$ gave $BzPh$ and $MeNH_2$; $H_2NCH_2C(CH_2Ph)_2OH$ gave $(PhCH_2)_2CO$ and $MeNH_2$. The same products were also obtained in smaller yield by heating the amino alcs. in the dry state at 150-80°. VII. *Deamination of 2-amino-1,1-dibenzyl-1-ethanols.* *Ibid.* 197-201.—The removal of NH_2 from $RCH(NH_2)C(CH_2Ph)_2OH$ by the action of HNO_2 is accompanied by migration of CH_2Ph from the adjacent C, in a manner analogous to that previously demonstrated for the corresponding Ph_2 derivs. $H_2NCH_2C(CH_2Ph)_2(OH)$ gave 93.8% of *benzyl phenethyl ketone* b_{11} 206° (decompn.); *oxime m.*

120°. 2-Methyl-2-amino-1,1-dibenzyl-1-ethanol, m. 96.5°, prep'd. in 86.3% yield from alanine ester-HCl and MgPhCH_2Br , gave 30% of benzylmethylcarbinyl benzyl ketone, b₂₅ 210–2°. $\text{PhCH}(\text{NH}_2)\text{C}(\text{CH}_2\text{Ph})_2\text{OH}$ gave 78.87% of phenylbenzylcarbinyl benzyl ketone, m. 77–8°. $\text{PhCH}_2\text{CH}(\text{NH}_2)\text{C}(\text{CH}_2\text{Ph})_2\text{OH}$ gave 83.33% of dibenzylcarbinyl benzyl ketone, m. 62–4°.

A. W. DOX

The action of mercuric acetate on *o*-chloroaniline. L. VECCHIOTTI AND A. MICHETTI. *Gazz. chim. ital.* 55, 372–84 (1925); cf. C. A. 19, 49. By the action of $\text{Hg}(\text{OAc})_2$ on *o*- $\text{ClC}_6\text{H}_4\text{NH}_2$ 4 mercuriated compds. are formed the constitutions of 3 of which were det'd. To 32 g. $\text{Hg}(\text{OAc})_2$ in 300 cc 33% EtOH + a few cc. of AcOH was added 13 g. *o*- $\text{C}_6\text{H}_4\text{NH}_2$ in EtOH . After 48 hrs. a white ppt. was filtered off, dissolved in NH_4OH in the presence of NH_4OAc and reprecip'd. by neutralizing the soln. with AcOH . The monoacetatomercuri-*o*-chloroaniline 2,4- $\text{Cl}(\text{AcOHg})\text{C}_6\text{H}_3\text{NH}_2$ (I), thus obtained m. 134°. I was dissolved in 50% KOH and after 24 hrs. H_2O was added. The monomercuri-*o*-chloroaniline hydroxide ppt'd. does not m. but decomp. 205°. I allowed to react with excess coned. HCl sep'd. in 24 hrs. monomercuri-*o*-chloroaniline chloride that does not m. but decomp. 174°. I with Ac_2O on the H_2O bath gave the *Ac* deriv. (II) of I. I digested 24 hrs. with an excess of 50% $\text{Na}_2\text{S}_2\text{O}_3$ gave 4-monomercuri-*bi*-*o*-chloroaniline [$4,3\text{-Cl}(\text{H-N})\text{C}_6\text{H}_3$] $_{\text{2}}\text{Hg}$ (III), m. 138°. 10 g. II in glacial AcOH with the calcd. amt. of CaCl_2 was treated with Cl gas until the ppt first formed dissolved. NaCl was added to salt out the 2,4- $\text{Cl}_2\text{C}_6\text{H}_3\text{NHAc}$ (m. 143°), formed, thus proving the constitution of I. From the mother liquors from I was sep'd. an isomer, $\text{C}_8\text{H}_6\text{O}_2\text{NClHg}$, yellowish, m. 143°, of which the constitution was not det'd. because of the lack of material. To 32 g. $\text{Hg}(\text{OAc})_2$ in 100 cc. of H_2O was added 13 g. *o*- $\text{ClC}_6\text{H}_4\text{NH}_2$ and a resin was formed that was filtered off. The filtrate became gelatinous after a time. This was boiled after adding a little AcOH and sep'd. white α -biacetatomercuri-*o*-chloroaniline, 2,4,6- $\text{Cl}(\text{AcOHg})_2\text{C}_6\text{H}_2\text{NH}_2$ (IV), that does not m. but decomp. at 220°. IV treated with 50% KOH for 24 hrs. was dild. with H_2O and sep'd. yellow α -bimercuri-*o*-chloroaniline hydroxide. IV with coned. HCl gives the corresponding chloride, $\text{C}_8\text{H}_4\text{NCl}_2\text{Hg}_2$, which does not m. but decomp. at 190°. IV with Ac_2O gave the *Ac* deriv. (V), $\text{C}_{12}\text{H}_{12}\text{O}_5\text{NClHg}_2$, m. 230°. 4.5 g. V in glacial AcOH with 0.74 g. CaCl_2 in EtOH gave a white ppt. of the chloride of the *Ac* deriv., $\text{C}_8\text{H}_6\text{ONClHg}_2$, decomp. 276°. IV was treated in the cold with 50% $\text{Na}_2\text{S}_2\text{O}_3$ for a long time and gave 4,6-monomercuri-2-chloroaniline (VI) or 4,6-bimercuri-*bi*-*o*-chloroaniline (VII) that decomp. at 200°. V in glacial AcOH with the calcd. amt. of CaCl_2 gave a white ppt. that was decomp'd. with Cl . On adding H_2O and NaCl , 2,4,6- $\text{Cl}_3\text{C}_6\text{H}_2\text{NHAc}$, m. 201°, was sep'd. To 96 g. $\text{Hg}(\text{OAc})_2$ in 900 cc 66% EtOH with a little AcOH was added 13 g. *o*- $\text{NH}_2\text{C}_6\text{H}_4\text{Cl}$ in EtOH . After a time there sep'd. a white ppt. of β biacetatomercuri-*o*-chloroaniline (VIII), m. 232°, which is different from IV. A tri-Hg deriv. was not obtained. VIII with Ac_2O gave the *Ac* deriv., $\text{C}_{12}\text{H}_{12}\text{O}_5\text{NClHg}_2$, m. 230°. VIII with 50% $\text{Na}_2\text{S}_2\text{O}_3$ gave after digestion for 24 hrs. 4,5-monomercuri-2-chloroaniline (IX) or 4,5-bimercuri-*bi*-*o*-chloroaniline (X), decomp. 160°. VIII in glacial AcOH with the calcd. amt. of CaCl_2 gave a ppt. which was decomp'd. with Cl . On dilg. and adding NaCl 2,4,5- $\text{Cl}_3\text{C}_6\text{H}_2\text{NHAc}$, m. 185°, was sep'd., thus proving the constitution of VIII.

E. J. WITZEMANN

The nitration of symmetrical arylalkylureas. L. C. E. KNIPHORST. *Rec. trav. chim.* 44, 693–727 (1925) (In English).—Earlier work on the nitration of urea and its derivs. is reviewed. By coupling EtNCO with PhNH_2 and some of its derivs. substituted in the nucleus (*o*- and *p*- $\text{ClC}_6\text{H}_4\text{NH}_2$, *o*- and *p*-toluidine and *p*- $\text{BrC}_6\text{H}_4\text{NH}_2$) some new sym-arylethylureas were prep'd. These were nitrated with an excess of abs. HNO_3 . PhNHCONHEt (I) with an excess of abs. HNO_3 with cooling gives α -2,4-dinitrophenyl- β , β -ethylnitrourea (II), 2,4- $(\text{NO}_2)_2\text{C}_6\text{H}_3\text{NHCONHEtNO}_2$, decomp. about 64°. The -NEtNO_2 group in II is mobile and by the action of H_2O , MeOH , EtOH , NH_3 , MeNH_2 , PhNH_2 , *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$, NH_2NH_2 and PhNHNH_2 can be replaced by the groups -OH , -OMe , -OEt , -NH_2 , -NHMe , -NHPh , $\text{-NHC}_6\text{H}_4\text{Me}(p)$, -NHNH_2 and -NHNHPh , resp., giving besides HNEtNO_2 in each case the following compds. ROH ($\text{R} = 2,4\text{-(NO}_2)_2\text{C}_6\text{H}_3\text{NHCO}$), ROMe , ROEt , RNH_2 , RNHMe , RNHPh , $\text{RNHC}_6\text{H}_4\text{Me}$,

RNHNH_2 and RNHNHPh , resp. Previous instances of this reaction with NH_2NH_2 and PhNHNH_2 were not known. I with excess abs. HNO_3 and concd. H_2SO_4 gives easily α -2,4,6-trinitrophenyl- β , β -ethylnitrourea (**III**), decomp. 60 – 105° . It is remarkable that here 3 NO_2 groups are easily introduced into the nucleus with $\text{HNO}_3 + \text{H}_2\text{SO}_4$, while Reudler (C. A. 8, 2373) found that with phenylurea only 2 NO_2 groups are introduced with $\text{HNO}_3 + \text{H}_2\text{SO}_4$. From this it is concluded that the Et group attached to the β -N atom exerts an influence on substitution in the Ph group. The observation of R. was repeated and the result confirmed. The $-\text{NHNO}_2$ group in **III** is easily replaceable by $-\text{OH}$, $-\text{OEt}$ and $-\text{NH}_2$. $p\text{-RC}_6\text{H}_4\text{NHCONHEt}$ ($\text{R} = \text{Me}, \text{Cl}, \text{Br}$) with abs. HNO_3 give α ,4-methyl-, decomp. 110° , α ,4-chloro-, decomp. 60° and α ,4-bromo-2,6-dinitrophenyl- β , β -ethylnitrourea, decomp. 100 – 5° , resp. These compds. have analogous constitution and properties to **II**. $o\text{-MeC}_6\text{H}_4\text{NHCONHEt}$ with excess abs. HNO_3 gives mainly α ,2-methyl-4,6-dinitrophenyl- β , β -ethylnitrourea (**IV**), m. 90° (decompn.). The derivs. of $o\text{-MeC}_6\text{H}_4\text{NH}_2$ were difficult to nitrate in the nucleus so that even on treatment with abs. $\text{HNO}_3 + \text{H}_2\text{SO}_4$ besides **IV** small quantities of mono-nitrated by-products were always present. $o\text{-ClC}_6\text{H}_4\text{NHCONHPh}$ (**V**) with an excess abs. HNO_3 gives α -2-chloro-4,6-dinitrophenyl- β , β -ethylnitrourea, decomp. 50 – 90° . In this case lower nitration products were not present as in the formation of **IV**. It is remarkable that while in the nitration of **V** 2 NO_2 groups are easily introduced 2,4,6- $\text{Cl}(\text{O}_2\text{N})_2\text{-C}_6\text{H}_2\text{NHAc}$ (**VI**) cannot be prep. by the nitration of $o\text{-ClC}_6\text{H}_4\text{NHAc}$ even with abs. $\text{HNO}_3 + \text{concd. H}_2\text{SO}_4$. However, **VI** can easily be obtained by acetylation of 2,4,6- $\text{Cl}(\text{O}_2\text{N})_2\text{C}_6\text{H}_2\text{NH}_2$ (obtained by chlorinating 2,4- $(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{NH}_2$) with the calcd. amt. of $\text{Ac}_2\text{O} + \text{H}_2\text{SO}_4$ (trace). PhNHCONHEt with 3 mols. of $\text{EtNO}_3 + \text{H}_2\text{SO}_4$ gave only α -2,4-dinitrophenyl- β -methylurea. If a large excess of abs. HNO_3 is used α -2,4-dinitrophenyl- β , β -methylnitrourea is formed, while with an excess of abs. HNO_3 and concd. H_2SO_4 α -2,4,6-trinitrophenyl- β , β -methylnitrourea is produced. Also $p\text{-MeC}_6\text{H}_4\text{NHCONHMe}$ with excess abs. HNO_3 easily gave α -4-methyl-2,6-dinitrophenyl- β , β -methylnitrourea. With PhNHCSNH_2 and $p\text{-MeC}_6\text{H}_4\text{NHCSNHMe}$ (**VII**) nitration takes place in the Ph group and at the same time the $>\text{C}=\text{S}$ group is oxidized to $>\text{C}=\text{O}$ so that the same products are formed as in the nitration of the corresponding ureas. Under the influence of the reduction products formed from the HNO_3 , rapid decompn. of the nitroamides formed occurs. This was especially the case with **VII**. In all cases investigated the group $-\text{NRNO}_2$ in the sym-arylalkylnitroureas mentioned was easily replaced by $-\text{OH}$, $-\text{OMe}$, $-\text{OEt}$, $-\text{NH}_2$, $-\text{NHPh}$, $-\text{NHNH}_2$ and $-\text{NHNHPh}$. The arylureas obtained by treating the compds., ArNH.CO.NRNO_2 with abs. EtOH-NH_3 in the cold appear to behave very differently on heating with $\text{NH}_3\text{-EtOH}$ to 100° . While the mononitroureobenzoic acids, $\text{HO}_2\text{C}(\text{NO}_2)\text{C}_6\text{H}_4\text{NHCONH}_2$ from their formation from the dinitroureobenzoic acids of Griess, $\text{HO}_2\text{C}(\text{NO}_2)\text{C}_6\text{H}_3\text{NHCONHNO}_2$, on heating 0.5 hr. with aq. NH_3 are fairly stable, Reudler found that from 2,4- $(\text{NO}_2)_2\text{C}_6\text{H}_3\text{NHCONHNO}_2$ only 2,4- $(\text{NO}_2)_2\text{C}_6\text{H}_3\text{NH}_2$ was produced by heating with aq. NH_3 . Thus 2,4-dinitrophenylurea, which he obtained by treating 2,4-dinitrophenyl- β -nitrourea in ethereal suspension with NH_3 , appears to be unstable towards aq. NH_3 . All the arylureas obtained in this work are unstable towards aq. NH_3 and many even were more or less quickly decompd. with the formation of the corresponding aniline deriv. by heating to 100° with abs. EtOH-NH_3 .

E. J. WITZEMANN

Acetyldiphenylamine from ketenes. CHARLES D. HURD. *J. Am. Chem. Soc.* 48, 291 (1926).—Contrary to the statement of van Alphen (C. A. 19, 1253) ketene reacts with Ph_2NH in ice-cold Et_2O , giving 33% of the Ac deriv.; if the reaction flask is not cooled, the yield is about 8%.

C. J. WEST

Monophenyltetraaminobenzene and some of its derivatives. F. KEHRMANN AND (Miss) L. STANOVÉVITCH. *Helvetica Chim. Acta* 8, 663–8 (1925).—3- $\text{ClC}_6\text{H}_4\text{NHAc}$, added to 1 part HNO_3 (d. 1.52) and 3 parts H_2SO_4 at 0° , gives 4,6-dinitro-3-chloroacetanilide, yellow, m. 136° , identified as the free amine (Nietzke and Schedler, *Ber.* 30, 1666 (1897)); boiled with 5 mols. PhNH_2 it yields 2,4-dinitro-5-acetaminodiphenylamine, orange, m. 233.5° , which, heated below 80° with H_2SO_4 (2:1) until dissolved, gives 2,4-dinitro-5-amminodiphenylamine, sulfonation occurring at higher temps., orange, m. 205° (undoubtedly a misprint for 205° —ABSTR.); with Sn, concd. HCl , and a little alc. it yields the monophenyltetraaminobenzene, isolated after decompn. of the double Sn salt as the tri- HCl salt (**I**), sensitive to air and light. With phenanthrenequinone in 90% alc. on the H_2O bath **I** gives both the azine, which was not obtained pure and the phenazonium compd., dissolved after addn. of H_2O and NaOH by extg. the bases with 15–20% HOAc ; nitrate, red needles with green metallic luster, sol. in hot H_2O with a red color, in H_2SO_4 with a red color (tetra-acid salt), passing on diln. successively through violet and bluish green to red; chloride; chloroplatinate, dark red; perchlorate, red, with

green metallic luster. I also yields both possible products with $(\text{PhCO})_2$ in alc. contg. a little dil. HCl, the *phenazonium compd.* predominating and crystg. as the *chloride*, pptd. completely with Et_2O , and purified by extn. with boiling H_2O , brick-red, with green reflex, has a bitter taste; *chloroplatinate*, brick-red; *perchlorate*, dark orange, sol. in H_2SO_4 with a reddish violet color. I and 1,2,4,5- $(\text{PhNH})_2\text{C}_6\text{H}_2(\text{:O})_2$ condense to give 4 different substances, whose study has not been completed, and only 1 of which is the expected induline.

M. IIIDELBERGER

A reaction between phenylhydrazine and mercuric acetate. L. VECCHIOTTI AND A. CAPODACQUA. *Gazz. chim. ital.* **55**, 369-71 (1925).—Fischer (*Ann.* **190**, 99) treated PhNHNH_2 in H_2SO_4 with yellow HgO and obtained diazobenzeneimide and diazobenzene sulfate. With PhNHNH_2 in Et_2O yellow HgO gave rise to N_2 and HgPh_2 (Fischer, *Ann.* **199**, 332). To 32 g. $\text{Hg}(\text{OAc})_2$ in 100 cc. H_2O were added 7 g. PhNHNH_2 . A green-brown ppt. mixed with drops of Hg was formed. After a time this ppt. was filtered off, washed with H_2O , dried and boiled with C_6H_6 . This soln. on cooling sepd. the Hg salt of diazoaminobenzene (I), $(\text{PhN}\cdot\text{NNPh})_2\text{Hg}$, gold-yellow, m. 232° (Ciusa, Pestalozza, *C. A.* **5**, 3106). The residue insol. in C_6H_6 was found to be HgOAc . The course of the reaction was not detd. experimentally but probably PhNHNH_2 is oxidized, giving PhNH_2 and $\text{PhN}\cdot\text{NPh}$; these 2 compds. copulate, giving $\text{PhN}\cdot\text{NNHPh}$, which reacts with $\text{Hg}(\text{OAc})_2$, giving I.

E. J. WITZEMANN

Rearrangement of hydroxamic acids isomeric with triphenylacetohydroxamic acid. L. W. JONES AND F. B. ROOT. *J. Am. Chem. Soc.* **48**, 181-95 (1926).—The benzohydroxyl-benzohydroxamic acids undergo rearrangement with great difficulty, which is in marked contrast to the ease of rearrangement of triphenylacetohydroxamic acid. Since they contain a radical (benzohydroxyphenyl) which is isomeric with Ph_2C , the radical found in triphenylacetohydroxamic acid, it is conclusively shown that the mass of the radical is not the factor that det. the ease of rearrangement in reactions of the Lossen-Hofmann-Curtius type. Therefore, the ease of rearrangement seems to be related in some way to the tendency of the radical to exist as a free radical. *p*-Benzohydroxylbenzohydroxamic acid (I), $(\text{Ph}\cdot\text{CH})\text{C}_6\text{H}_4\text{CONHOH}$, m. $156-7^\circ$, in 3 g. yield from 5 g. of the acid chloride and NH_4OH ; *Bz deriv.* insol in warm alkali, mol. wt. in camphor, 386, 420; *K salt*, puffs at 91° ; boiling with H_2O 0.5 hr. gives quant. *sym-di-p*-benzohydroxylphenylurea (II), m. $262-3^\circ$; the rearrangement in EtOH required heating in a sealed tube at 100° and gave some II (0.08 g. from 0.4 g. *K salt*) and 0.28 g. *p*-benzohydroxylphenylurethane (III), m. 103° . The *Na salt*, decomp. 109° , becomes turbid when the aq. soln. is boiled. *Ag salt*, decomp. about 190° , darkens slowly in the light. *Ac deriv.* of I, m. $157-8^\circ$ (quant. yield); *K salt*, decomp. 130° and rearranges like that of the *Bz deriv.*; *Na salt*, decomp. 140° ; *Ag salt*, darkens 150° , decomp. 200° . *p*-Benzohydroxylbenzamide, m. 149° (quant. yield); with 3.3 equivs. of Br and EtONa there results 53% of III. *p*-Benzohydroxylphenyl isocyanate, which was not isolated, gives with *p*-benzohydroxylaniline II. *Hydroxylammonium o*-benzohydroxylbenzoate, m. $146-8^\circ$ (decompn.); decompn. by heating at 150° gave only the free acid but no hydroxamic acid. NH_4OH and MeONa react very slowly with the Me ester. SOCl_2 and the acid give 9-phenyl-9-chloroanthrone, m. 164° . In CHCl_3 , SOCl_2 gives the *o*-benzohydroxylbenzoyl chloride, pale yellow, m. 85° , which, with NH_4OH gives *o*-benzohydroxylbenzohydroxamic acid, m. $177-8^\circ$ (decompn.); at 180° it decomp., giving *sym-di-o*-benzohydroxylphenylurea (IV), m. 196° , which was synthesized from COCl_2 and *o*- $\text{Ph}_2\text{CHC}_6\text{H}_4\text{NH}_2$. *o*-Benzohydroxylbenzamide, m. $129-30^\circ$; the anilide m. $152-3^\circ$; oxidation of the amide with Cr_2O_3 gives diphenylphthalide. The *Bz deriv.* of the acid, m. $118-20^\circ$ and gives IV when heated with KOH for 2 hrs. The *K salt* darkened slightly at 200° ; in boiling H_2O it slowly rearranges to IV. *Ag salt*, darkens above 210° . *m*-Benzohydroxylbenzoic acid, m. 179° , from the amine through the nitrile.

C. J. WEST

Chemotherapy of antimonial compounds in kala-azar infection. XV. Further observations on certain derivatives of *p*-aminobenzenestibonic acid. U. N. BRAHMACHARI AND JUDHISTHIR DAS. *Indian J. Med. Research* **13**, 17-9 (1925); cf. *C. A.* **19**, 2707.—Four compds. are prepd.: (1) To 500 cc. cold aq. (2%) *p*- $\text{AcNHC}_6\text{H}_4\text{SbO}(\text{ONa})_2$ is added 140 cc. NaOCl (= 2 g. Cl) and stirred vigorously 0.5 hr. Add AcOH in excess, stir in cold and after 1 hr. filter. Collect the ppt.; dissolve in excess NH_4OH ; reppt. with dil. AcOH and wash the ppt. with water. Dissolve in NaOH , neutralize with dil. AcOH , filter and con. The ppt. formed by adding abs. alc. is chlorostibaceticin, $\text{C}_8\text{H}_9\text{O}_6\text{NCISbNa}$. (2) Pure *p*- $\text{H}_2\text{NC}_6\text{H}_4\text{SbO}_3\text{H}_2$ is dissolved in the least quantity of NH_4OH , neutralized with dil. AcOH and pptd. with abs. alc. The ppt. is NH_4 stibamine, $\text{C}_{18}\text{H}_{23}\text{O}_7\text{N}_4\text{Sb}_3$. (3) 8 g. stibamine is dissolved in 40 cc. glucose soln. (= 6 g.), heated at 60° for 2 hrs. filtered and concd.; pptd. with abs. alc., washed 2 times with EtOH - H_2O (4:1) and then with abs. alc. The ppt. is glucose-stibamine, a yellowish powder,

very easily sol. in water. (4) Combination of NH_4 stibamine and glucose by the same procedure as (3) yields glucose- NH_4 stibamine.

FRANCES KRASNOW

Chemotherapy of antimonial compounds in kala-azar infection. XVII. Further details of the preparation of urea stibamine. U. N. BRAHMACHARI. *Indian J. Med. Research* **13**, 111-2(1925); cf. *C. A.* **20**, 450. $p\text{-H}_2\text{NC}_6\text{H}_4\text{NHAc}$ (1 mol) is added to well-cooled H_2SO_4 (1.5 mols) of 1000 cc. water. The mixt. is diazotized, added to a Na antimonate soln. and rapidly cooled to 0° . The greater portion of the alkali is neutralized with dil. H_2SO_4 and the last traces by satn. with CO_2 . The soln. is filtered and $p\text{-AcNHC}_6\text{H}_4\text{SbO}_3\text{Na}_2$ is pptd. by NaCl satn. The aq. soln. of the ppt. is satd. with CO_2 , filtered and treated with dil. HCl. $\text{AcNHC}_6\text{H}_4\text{SbO}_3\text{H}_2$ is pptd. This product is heated with 5% aq. NaOH (10 parts) until a ppt. forms on the addn. of dil. HCl and dissolves in excess. Addn. of dil. AcOH to the cooled soln. ppts. $\text{H}_2\text{NC}_6\text{H}_4\text{-SbO}_3\text{H}_2$. The latter, suspended in water, dissolves on the addn. of urea. The resulting soln. is filtered, concd., cooled and mixed with alc. Urea stibamine is pptd.

FRANCES KRASNOW

Selenium organic compounds. VI. Bromine, sulfo and mercury derivatives of 2,4-diphenylselenophene and experiments with some related compounds. M. T. ROBERT AND C. N. ANDERSEN. *J. Am. Chem. Soc.* **48**, 223-31(1926), cf. *C. A.* **19**, 1863. Attempts to prep. 2-methyl and 2,4-dimethylselenophene failed. 2,5-Selenoxene and $o\text{-C}_6\text{H}_4(\text{CO})_2\text{O}$ are condensed by AlCl_3 in CS_2 , giving 7% of *phthalylselenoxene*, pale yellow m. 155.5° (all m. ps. are cor.), giving with concd. H_2SO_4 a deep red color. In the prepn. of 2,4-diphenylselenophene (I), a temp. of $235\text{--}40^\circ$ for 20 hrs. increased the yield from 30 to 90%. 3,5-Dimethyl-2,4-diphenylthiophene, m. 163.8° , gives a yellow color with HNO_3 and a yellowish brown color with H_2SO_4 . The corresponding fusion with Se gave no cryst. products. *Butyrophenone anil*, pale yellow, b_p $198\text{--}202^\circ$ (60% yield); with S at $200\text{--}20^\circ$ for 8 hrs., there results 3,5-diethyl-2,4-diphenylthiophene(?), m. 286° . I (5 g.) and 10 g. of Br in glacial AcOH at room temp. give 80% of a *di-Br deriv.*, m. 86.7° ; 1.5 g. I in AcOH contg. a very small amt. of I and 10 g. Br, kept in the dark 48 hrs. at room temp., give 36% of a *tri-Br deriv.*, pale straw color, m. 126.7° . MeI and Na give a *compd.* $\text{C}_{17}\text{H}_{11}\text{BrSe}$, m. 139.8° . In boiling EtOH in direct sunlight there results a *tetra-Br deriv.*, m. 176.5° , in 30% yield. I *tetrakisulfonic acid*, m. above 300° , in very poor yield from I and ClSO_3H . 5-Bromomercuri deriv. of I, m. 215° , in 50% yield from I and HgBr_2 in EtOH contg. AcONa; boiled with PhMe it gives I and HgBr_2 ; the 5-I *deriv.*, m. 176° , reddens rapidly in the light (30% yield); the 5-cyano *deriv.*, m. 256.4° (50% yield from the 5-Cl *deriv.* and NaCN). Mercuribis-[2,4-diphenylselenophenone-5], pale gray, m. 236.7° .

C. J. WEST

Beckmann rearrangement involving optically active radicals. L. W. JONES AND E. S. WALLIS. *J. Am. Chem. Soc.* **48**, 169-81(1926).—*Me d-benzylmethylacetate*, $[\alpha]_D^{20}$ 26.75° (100 mm. tube). A mixed *l-ester* showed a rotation of -12.66° . *d-Benzylmethylacetohydroxamic acid*, m. 121.5° , $[\alpha]_D^{20}$ 63.2° (1.2817 g. in 50 cc. EtOH), from the *Me ester* and free NH_2OH ; the *dl-acid*, m. 124.4° ; the mixed *l-form*, m. $118.5\text{--}20^\circ$, $[\alpha]_D^{20}$ -31.1° . After 12 weeks, these acids showed no appreciable racemization. The *Bz ester* of the *dl-acid*, m. $119\text{--}20^\circ$; of the *d-acid*, m. 116° , $[\alpha]_D^{20}$ 54.5° (1.0054 g. in 50 cc. EtOH); of the mixed *l-acid*, $114\text{--}6^\circ$, $[\alpha]_D^{20}$ -25.3° . Warming with dil. NaOH causes rearrangement. The K salt, which ppts. from $\text{Et}_2\text{O-EtOH}$ at -12° and may be dried *in vacuo*, puffs when exposed to the air and spontaneously rearranges. *sym-Dibenzylmethylmethylurea* (I), m. 199° . The product from the optically active ester showed no appreciable rotation in EtOH; it is possible that racemization occurred during its formation, in which heating to $80\text{--}90^\circ$ is required. *d-Benzylmethylacetazide*, unstable liquid, decomps. slowly at about 10° , in a 50-mm. tube at 5° gave a rotation of 30.77° ; in H_2O the isocyanate first formed is hydrolyzed to I. In C_6H_6 there results the *d-isocyanate*, b_p 82° , α 28.75° at 20° (50 mm. tube); $[\alpha]_D^{20}$ 52.5° (0.9433 g. in 50 cc. C_6H_6); the completeness of the rearrangement is 97%. *d-Benzylmethylmethylurea*, m. 136° , $[\alpha]_D^{20}$ 10.7° (1.870 g. in 50 cc. Me_2CO); the *dl-deriv.* m. 149° ; a mixt. of 5% *dl-* and 95% *d-urea* m. 133° . The *d-isocyanate* and concd. HCl give *d-benzylmethylmethylamine-HCl*, m. 147° , $[\alpha]_D^{20}$ 16.6° (1.20 g. in 25 cc. H_2O). The velocity of rearrangement of benzylmethylacetazide at 35° corresponds to that of a unimol. reaction; $k_{35} = 0.01178$.

C. J. WEST

Glucosides of chalcones. G. BARGELLINI AND P. LEONE. *Atti accad. Lincei* [6], **2**, 35-9(1925).—In a previous paper (*C. A.* **9**, 1317) a method was described for the prepn. of glucosides of hydroxychalcones by the action of substituted acetophenones on

the glucoside of salicylic acid (I). The chalcone glucosides described in this paper were obtained by condensing aromatic aldehydes with *p*-hydroxyacetophenone glucide (picein) (II). Fruitless attempts were also made to condense I with II. II was obtained according to Mauthner (*C. A.* 8, 1097) by the action of aq. NaOH on a mixt. of $p\text{-HOC}_6\text{H}_4\text{COMe}$ and β -acetobromoglucose in Me_2CO ; the product (III) sapond. with $\text{Ba}(\text{OH})_2$ gives II, m. 193–4°, identical with that obtained from *Pinus picea* by Tanret (*Bull. soc. chim.* [3] 19, 944(1894)). In the condensation B. and L. preferred to use the *tetraacetyl picein* (III) rather than II. To a mixt. of 0.45 g. BzH , 2 g. III and 25 cc. EtOH 5 cc. 40% NaOH was added drop by drop. III slowly dissolved and after 12 hrs. the soln. was acidified with dil. HCl. 4'-Hydroxychalcone glucoside, $\text{PhCH:CHCOC}_6\text{H}_4\text{OC}_6\text{H}_{11}\text{O}_6$, was pptd. and crystd. from EtOH, yellow, m. 195°. III condensed in the same way with anisaldehyde gave 4'-hydroxy-4-methoxychalcone glucoside, yellow, m. 183°; with vanillin 4,4'-dihydroxy-3-methoxychalcone glucoside, golden, m. 193°; with piperonal 4'-hydroxy-3,4-methylenedioxychalcone glucoside, yellow, m. 181°; with furfural under the same conditions *fural-p*-hydroxyacetophenone glucoside, gold crystals from dil. EtOH contg. 1 H_2O of crystn.; with PhCH:CHCHO cinnamylidene-*p*-hydroxyacetophenone glucoside, m. 185°.

E. J. WITZEMANN

Isomeric esters of *p*-phenoxybenzoylacrylic acid. GRACE P. RICE, *J. Am. Chem. Soc.* 48, 269–74(1926); cf. *C. A.* 19, 3369.—*Me p*-phenoxybenzoylpropionate, b_{16} 252°, m. 59°, in 91% yield by satg. the MeOH soln. of the acid with HCl; *Et ester*, b_{16} 255°. Bromination followed by the removal of HBr gave the unsatd. esters. *Me p*-phenoxybenzoylacrylate (I), yellow, m. 93°; *Et ester* (II), yellow, m. 46° (*dibromide*, m. 78° (decompn.)). The free acid, yellow, m. 121°; bromination in AcOH at 0° gives a *dibromide*, m. 156° (decompn.); in CHCl_3 a *dibromide*, m. 116–9°. A satd. C_6H_6 soln. of I, exposed to sunlight for 3 weeks, gave the colorless form (III), m. 83°; in dil. soln. the change is incomplete; III in C_6H_6 contg. a trace of I is completely changed to I. When the powd. I is exposed to light in a thin layer, there results a polymer, $\text{C}_{34}\text{H}_{28}\text{O}_8$, m. 167°, mol. wt. in CHCl_3 , 561, 568. II in C_6H_6 likewise gives a colorless isomer, liquid; the reverse transformation takes place in the presence of I. The free acid in C_6H_6 was unchanged after an exposure of 4 weeks. The solid acid on exposure did not give an isomer, but decompd. III is transformed into I by concd. HCl in 3 hrs. The acid hydrolysis of the yellow esters is discussed. α -Hydroxy-*p*-phenoxybenzoylpropionic acid(?), m. 120°. III or I in MeOH and 2 equivs. of $\text{H}_2\text{NCONHNH}_2\cdot\text{HCl}$ with AcONa give α -semicarbazidomethyl *p*-phenoxybenzoylacrylate, m. 184°. The *Et deriv.*, m. 178°. I and 1 equiv. of $\text{H}_2\text{NCONHNH}_2$ give the isomeric semicarbazones, pale yellow, m. 141° and 150°. II gives the semicarbazones, m. 156° and 85°.

C. J. WEST

Hydroxyamino acids. I. FRITZ BETTIECHE, *Z. physiol. Chem.* 150, 177–90 (1925).—Acid cleavage of β -hydroxy- α -amino acids yields an α -keto acid, whereas alkali cleavage gives an aldehyde and glycine, which may then undergo condensation into an amino alc. Thus, serine when refluxed with 15% H_2SO_4 splits off NH_3 with formation of AcCO_2H , which was identified by its phenylhydrazone. β -Phenylserine gave PhCH_2CHO , $\text{PhCH}_2\text{COCO}_2\text{H}$ and $\beta\text{-C}_{10}\text{H}_7\text{Ph}$ (I). By heating in a bomb tube at 160–70° the yield of I was increased to 65%. This, however, is a secondary reaction representing a simple condensation of 2 PhCH_2CHO with loss of 2 H_2O . By refluxing phenylserine with 10% NaOH a decompn. into BzH and glycine first occurs and then the 2 products react to form the benzal deriv. of 1,2-diphenyl-2-amino-1-ethanol. *N*-Toluenesulfo-phenylserine, m. 191–2°, was prepd. by shaking phenylserine, $\text{MeC}_6\text{H}_4\text{SO}_2\text{Cl}$ and NaOH and treatment of the sepd. Na salt with HCl. It is much more resistant to acid and alkali cleavage than is phenylserine.

A. W. DOX

The isonitriles. XII. Reaction between phenylisonitrile and α -naphthol. MARIO PASSERINI, *Gazz. chim. ital.* 55, 555–9(1925).—In preceding papers (*C. A.* 18, 1661, 3187; 19, 828, 829) the reaction between β -naphthol and aromatic isonitriles was described and interpreted. When α -naphthol (I) is used the corresponding 1-hydroxy-2-naphthylglyoxal is not formed but a more complex compd., 3-anil-2-dianilino-6,7-benzocumarandione $\text{O}—\text{C}(\text{NHPh})_2$ (II), m. 220° (decompn.). 6.5 g. I + 8.5 g.

PhNC in 10 cc. C_6H_6 were refluxed on the H_2O bath for 80–90 hrs.; 6 g. of II sepd. A small amt. of $\text{CO}(\text{NHPh})_2$ and another unidentified compd. are formed. 4.5 g. II was suspended in 20 cc. concd. HCl and boiled a few mins. A yellow ppt. of 1-hydroxy-2-naphthylglyoxylic acid (III), m. 147–9° (decompn.) was obtained. The soln. of III was neutralized with NH_4OH , BaCl_2 was added; the Ba salt was obtained as a yellow ppt. II sapond. in boiling HCl-EtOH pptd. the *Et ester* of III, yellow, 69–70°. 0.5 g. of III in 2 cc. AcOH was heated with a few drops of 30% H_2O on the H_2O -bath. CO_2 was

evolved and on cooling 1,2-C₁₀H₆(OH)CO₂H acid, m. 191–2° having the other known properties of this acid, sepd.

E. J. WITZEMANN

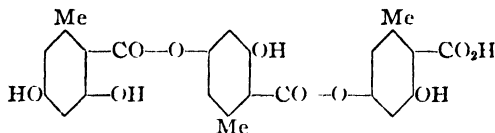

Reactions of ethyl aminocinnamates with bromine. H. W. UNDERWOOD, JR. AND E. L. KOCHMANN. *J. Am. Chem. Soc.* **48**, 254–7 (1926).—Nitration of cinnamic acid gives 17 and 43% of the *o*- and *p*-NO₂ derivs. Reduction of Et *o*-, *m*-, and *p*-nitrocinnamates gives 45, 60 and 53% of the corresponding NH₂ acids. Treatment of the *o*-ester with 8 and with 2 atoms of Br per mol. of ester yields a compd. contg. 4 atoms Br, 2 of which are apparently in the side chain. Upon reaction with an amt. of Br sufficient to sat. the double bond and to replace all sensitive H atoms in the ring, the *m*-ester is transformed into a compd. in which 5 atoms of Br are present; 2 of these are in the side chain. The use of 1 mol. of Br for 1 of ester yields a tri-Br deriv., in which all three halogen atoms are aromatic. Apparently substitution in the ring precedes addn. in the double bond. The *p*-ester, treated with an excess of Br, gives a compd. with 3 atoms Br, only 1 of which is in the side chain. It may be assumed that Br first enters the ring and that the HBr thus formed adds to the aliphatic unsatd linkage. If 2 atoms Br for 1 mol ester are employed, a tarry mixt. is secured. The compd. C₁₁H₁₁O₂NBr₄, m. 251–3°, light yellow; *perbromide*, dark red, m. 235–9°; compd., C₁₁H₁₀O₂NBr₅, from *m*-ester, m. 145°; compd. C₁₁H₁₀O₂NBr₃, m. 110°; the compd. C₁₁H₁₀O₂NBr₃, from the *p*-ester, m. 112.5°.

C. J. WEST

Syntheses in organic chemistry with radiant energy. I. The photosynthesis of α -phenyl- β -diphenyllactic acid. REMO DE FAZI. *Atti accad. Lincei* [6] **6**, 266–9 (1925).—Paternò and Chieffi (*C. A.* **5**, 2632) found on exposing Ph₂CO + PhCH₂CO₂H in C₆H₆ to sunlight for 5 months that benzopinacol (I) and triphenyllactic acid (II) are formed. Later de F. (*C. A.* **9**, 3063) found that I is α -phenyl- β -diphenyllactic acid (III). In opening the tubes after exposure to light de F. always found pressure due to CO₂. De F. noted that after a time the quantity of I + III sepd. did not increase further in 2 months and thought that equil. phenomena were involved. The tubes were opened to release the CO₂, the solid was filtered off and on sealing and exposing them to light again additional I + III sepd. in the course of a month. From the 2nd filtrate unchanged Ph₂CO and PhCH₂CO₂H were recovered as well as some PhCH₂CO₂CH₂Ph and some resin. Additional expts. have been set up in such a way as to absorb the CO₂ formed but these require much time and in the meantime a tentative interpretation of the reactions involved is here given.

E. J. WITZEMANN

Lichen substances. I. Gyrophoric acid. Y. ASAHINA AND N. KUTANI. *J. Pharm. Soc. Japan*, No. **519**, 423–9 (1925).—Analyses of gyrophoric acid (I) are given. According to Hesse (*J. prakt. Chem.* [2] **58**, 475 (1898)), I dried at 100° has the compn. C₂₆H₃₄O₇ and is an isomer of laccaric acid. H. later gave C₂₆H₃₄O₁₄ for I, basing his revision on b. p. detns. of I in Me₂CO. On account of the insoly. of I, A. and K. methylated I with CH₃N₂ and detd. its mol. wt. in PhOH. The result shows that even the Me deriv. of I has a mol. wt. of 500, far smaller than that of free I (639) if H. is correct. The air-dried substance, when dried *in vacuo* with toluene vapor, loses 1 mol. H₂O. The final substance contains C 61.44%, H 4.92%; and the Me deriv. has C 64.6%, H 6.18% and MeO 28%. From this and the chem. properties detd. by previous investigators, I must have the compn. C₂₄H₂₀O₁₀, and must be the tripeptide of orsellic acid,

Those plants in Japan which contain I and allied acids are *Gyrophora esculenta*. Miyoshi (0.43%); *Gyrophora proboscidea* L. (2.3% of the dry plant); *Lobaria pulmonaria* L. (0.2–0.5%).

S. T.

β -Phenylcoumarins. G. BARGELLINI. *Atti accad. Lincei* [6] **2**, 32–5 (1925).—Earlier methods of prepg. β -phenylcoumarins (I) (*C. A.* **5**, 3805) were improved by Sonn (*C. A.* **13**, 582) who obtained I from the action of nitriles of benzoylactic acids with phenols in the presence of HCl gas. E. v. Meyer (*J. prakt. Chem.* [2] **67**, 342 (1903)) had considered the products to be flavones but S. found them to be I. In this way S. prepd. 4,6-dihydroxy-4'-methoxy- β -phenylcoumarin (II). B. repeated this prepn. by S.'s method in order to obtain 4,6,4'-trihydroxy- β -phenylcoumarin (III) (HO)₂C₆H₂O.CO.CH:CC₆H₄OH, and some of its derivs. II was demethylated

by heating it with concd. HI or even with HBr + glacial AcOH. After boiling 4–5

hrs. the product was thrown into very dil. H_2SO_4 and sepd. **III**, yellow, m. $285-8^\circ$ (decompn.). **III** heated with $\text{Ac}_2\text{O} + \text{NaOAc}$ gave 4,6,4'-triacetoxy- β -phenylcoumarin, m. $185-7^\circ$. **II** was treated in MeOH with a slight excess of Me_2SO_4 and gradually with NaOH soln. in excess. The mixt. was dild. with H_2O , the MeOH was distd. off and on adding HCl gave 4,6,4'-trimethoxy- β -phenylcoumarin, m. $249-51^\circ$. **III** when heated with concd. KOH is sapond., giving $p\text{-HOC}_6\text{H}_4\text{CO}_2\text{H}$ and phloroglucinol, which are also produced under the same conditions from apigenin (trihydroxyflavone), campherol (trihydroxyflavonal) and by vitexin, durasantalol, sacuranetin, etc., of natural origin but of unknown constitution. E. J. WITZEMANN

α,β -Diphenylcoumarins. G. BARGELLINI. *Atti accad. Lincei* [6] 2, 178-82 (1925).—As is known *o* hydroxy aldehydes condense with NaOAc in the presence of Ac_2O giving coumarins; the corresponding benzophenones give β -phenylcoumarins (B. and Leonardi, *C. A.* 5, 3805). Just as *o*- $\text{HOC}_6\text{H}_4\text{CHO}$ condenses with $\text{PhCH}_2\text{CO}_2\text{H}$ giving α -phenylcoumarin (Ogialoro, *Gazz. chim. ital.* 9, 128 (1879)) so other substituted α -phenylcoumarins were obtained by the same method. To complete this work on α - and β -substituted coumarins B. studied the products obtained from *o*-HO substituted benzophenones (I) by which substituted α,β -diphenylcoumarins were obtained. Equimol. amts. of I + $\text{PhCH}_2\text{CO}_2\text{H}$ were heated 30 hrs. with 5 times their combined wt. of Ac_2O on a sand bath and then thrown into H_2O . In this way from 2,4-(HO) $_2\text{C}_6\text{H}_3\text{COPh}$ the *Ac* deriv. of α,β -diphenyl-4-hydroxycoumarin (**II**), ye. lowish, m. 220° , was obtained. This was sapond. at room temp. by concd. H_2SO_4 , giving free **II**, m. 290° . With 2,3,4-(HO) $_3\text{C}_6\text{H}_2\text{COPh}$ the *di-Ac* deriv. of α,β -diphenyl-3,4-dihydroxycoumarin (**III**), m. 255° (decompn.), was obtained; on sapon. **III**, m. $271-3^\circ$, was sepd. With 2,4,6-(HO) $_3\text{C}_6\text{H}_2\text{COPh}$ the *di-Ac* deriv. of α,β -diphenyl-4,6-dihydroxycoumarin (**IV**), m. 190° , was formed; this on sapon. gave **IV**, m. $260-5^\circ$. With 2,4,4'-(HO) $_3\text{C}_6\text{H}_3\text{COC}_6\text{H}_4\text{OMe}$ the *Ac* deriv. of α -phenyl- β -*p*-methoxyphenyl-4-hydroxycoumarin (**V**), m. $220-2^\circ$, was formed; this on sapon. gave **V**, m. 255° (decompn.). E. J. WITZEMANN

α -Phenyl- β -methylcoumarins. G. BARGELLINI. *Atti accad. Lincei* [6] 2, 261-6 (1925). In this paper the reaction described in the preceding abstr was extended to *o*-HO substituted acetophenones. B. believes that the reaction mechanism is analogous to that involved in the Ph_2CO derivs. and that α -phenyl- β -methylcoumarins (**I**) are formed. But the possibility that they are α -benzylchromones (**II**) cannot be excluded *a priori*. The yield of **I** is not high and the tar that is always formed, which is sol. in EtOH, may consist of chromones. The products isolated are thought to be **I** since their Me ethers are sol. in hot dil. alkalies and are reprecipitated unchanged by acids and this is not true of **II**. In another paper other reasons for considering these compds. as coumarins will be given. $\text{PhCH}_2\text{CO}_2\text{Na} + 2,4\text{-(HO)}_2\text{C}_6\text{H}_3\text{COMe}$ and Ac_2O were heated 30 hrs. and gave the *Ac* deriv. of α -phenyl- β -methyl-4-hydroxycoumarin (**III**), m. $180-2^\circ$; this, sapond. with concd. H_2SO_4 , gave **III**, m. 225° . **III** with BzCl gave the *Bz* deriv. **III** with $\text{Me}_2\text{SO}_4 + \text{NaOH}$ gave the *Me* ether (**IV**), m. $101-2^\circ$. Phenol condensed with $\text{PhCH}_2\text{CO}_2\text{H}$ gave **IV** also. 2,5-(HO) $_2\text{C}_6\text{H}_3\text{COMe}$ treated as above gave the *Ac* deriv. of α -phenyl- β -methyl-5-hydroxycoumarin (**V**), m. $170-3^\circ$; this sapond. gave **V**, m. 248° ; with Me_2SO_4 **V** gave the *Me* ether, m. $150-1^\circ$. Treated as above 2,3,4-(HO) $_3\text{C}_6\text{H}_2\text{COMe}$ gave the *di-Ac* deriv. of α -phenyl- β -methyl-3,4-dihydroxycoumarin (**VI**), m. $207-8^\circ$; this sapond. gave **VI** (decompn.), begins at 265° , m. 274° . With Me_2SO_4 **VI** gave the *di-Me* ether, m. $166-8^\circ$. 1,2- $\text{C}_{10}\text{H}_7(\text{OH})\text{Ac}$ (obtained by condensing α -naphthol with AcOH in the presence of ZnCl_2) treated as above gave α -phenyl- β -methyl-naphthocoumarin, m. $215-6^\circ$. E. J. WITZEMANN

Camphor group. I. Y. MURAYAMA. *J. Pharm. Soc. Japan*, No. 524, 882-4 (1925).—(a) Prepn. of camphor from turpentine oil (with K. OTSUKA). Two brands of the American oil were distd. over Na and portions b. $158-61^\circ$ were taken. Brand A had $d_{15} 0.8644$, $\alpha - 6.40^\circ$; Brand B, $d_{15} 0.8610$, $\alpha 9.20^\circ$. The oil was treated with anhyd. $\text{H}_2\text{C}_2\text{O}_4$ in the presence of FeCl_3 as a catalyst; the resulting ester was sapond. The yield of the crude borneol was 25%. The purified borneol from A had $[\alpha]_D^{16} -10.00$, and that from B $+10.00$. When these *d*- and *l*-borneols are oxidized with fuming HNO_3 , *d*- and *l*-camphor are obtained. The yield is 90%. (b) Prepn. of camphor from camphane-2-carboxylic acid (with S. TANAKA). 10 g. of camphane-2-carboxylic acid dissolved in a slight excess of dil. alkali were slowly mixed with 30 g. KMnO_4 and warmed on a water bath. On sublimation, there is obtained a white cryst. substance m. 175° , identified as camphor by its semicarbazone, m. 235° . S. T.

Reaction of potassium cyanide with the pernitroso derivatives. MARIO PASSERINI. *Gazz. chim. ital.* 55, 559-67 (1925); cf. also *C. A.* 19, 3087.—Five g. pernitrosocamphor in 15 cc. EtOH with 1.5 g. KCN in 15 cc. H_2O was boiled under a condenser for 20

min. The EtOH was largely evapd. and the *K* salt of 6-cyanocamphor-6-nitrosohydroxylamine (I) sepd. I in H₂O with dil. H₂SO₄ with dil. H₂SO₄ pptd. a colorless compd. which

(I)

(II)

decomps. at 85°, evolving N₂O and giving *camphor cyanohydrin* (II), m. 209-10°. II heated with a little concd. HCl dissolved quickly and then sepd. the corresponding *amide*, m. 198°. The HCl soln. was also boiled 80 hrs., dild. with H₂O and extd. with Et₂O. On evapg. the Et₂O a cryst. mass of 2 isomeric acids was obtained. This dissolved in hot C₆H₆ sepd. an *acid* C₁₁H₁₆O₂, m. 157-8°. The mother liquors were evapd. and the residue was crystd. from petroleum ether and gave an *acid*, m. 90-2°. II boiled with 10 times its wt. of 40% H₂SO₄ 6-7 hrs. gave a mixt. that on cooling solidified. Extd. with Et₂O and then crystd. from petroleum ether an *acid*, C₁₁H₁₆O₂, m. 137-8°, was obtained. The residue from the petroleum ether was distd. with steam 5 times and gave an *acid*, C₁₁H₁₆O₂, m. 108-10°. The constitution of these 4 acids has not been detd. 4.5 g. of pernitrosolenchone in 9 cc. EtOH with 2 g. KCN in 4.5 cc. H₂O were boiled 20 min. etc., as with I and gave after adding H₂O + dil. H₂SO₄ 6-cyanofenchane-6-nitrosohydroxylamine (III), decomps. 83-4°, gives a *Ag* salt, C₁₁H₁₆O₂N₃Ag. At 83-4° III loses N₂O, giving *fenchone cyanohydrin* (IV). This is composed of 2 compds., of which I is slowly dissolved and slowly sepd. from petroleum ether, while the other is quickly dissolved and quickly sepd. The latter m. 166-8°, [α]_D¹⁰ 5.15.12°, is considered to be IV; the other m. 100-2°, [α]_D¹⁰ 50.49°, is the isomer. 3 g. of the form, m. 166-8°, in 20 cc. of a satd. soln. of HCl gas in Et₂O was allowed to stand 3 days; crystals of an *amide*, C₁₁H₁₉O₂N, m. 170-2°, sepd. The isomer, m. 100-2°, was treated similarly and gave an *amide*, C₁₁H₁₉O₂N, m. 116-7°. These amides are sapond. by hot KOH, giving NH₃ and acids not yet isolated. E. J. W.

o-Hydroxybenzoyl-*o*-tetrachlorobenzoic acid, isophenoltetrachlorophthalein and some of their derivatives. W. R. ORNDORFF AND THEOPHILUS PARSONS. *J. Am. Chem. Soc.* **48**, 283-8(1926).—Tetrachlorophthalic anhydride and PhOH are condensed by AlCl₃ to give 82% of *o*-hydroxybenzoyl-*o*-tetrachlorophthalic acid (I), m. 210°; *di*-Ac deriv., m. 168°; the concd. H₂SO₄ soln. is bright orange. Heated with 30% NaOH for 1 hr., there results 5,6,7-trichloroxanthone-8-carboxylic acid, m. 262-5° (gas evolution); the concd. H₂SO₄ soln. is greenish yellow; the presence of the CO₂H group was demonstrated by the formation of a *Ba* and a *Na* salt. I and PhOH with SnCl₄ give 74% isophenoltetrachlorophthalein (II), m. 293°, sol. in concd. H₂SO₄ with a deep red color, which fades to a pale lemon-yellow on standing; alk. solns. are purple; the *p*_H value at the end point (reddish violet) is 9.2. Phenoltetrachlorophthalein, m. 307°. A by-product in the prepn. of II is tetrachlorofluoran, m. 298° (decompn). II *di*-Ac deriv., m. 189°; *di*-Bz deriv., m. 245° (red soln. in concd. H₂SO₄, by which it is sapond.); *di*-Me ether, m. 183° (the concd. H₂SO₄ soln., from which it is pptd. unchanged by H₂O) is deep blood-red). C. J. WEST

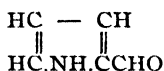

Tetrahydrofurfural (correction). HELMUTH SCHREIBLER, FRANZ SOTSCHKE AND H. FRIESE. *Ber.* **58B**, 1961(1925); cf. *C. A.* **19**, 278.—Measurements on larger amts. of the above substance have given the following consts.: *d*₂₀²⁰ 1.0749, *d*₄²⁰ 1.0727, *n*_D 1.43415, 1.43658, 1.44173 for α, D and β at 20°, *E*_D -0.32, -0.31, -0.33, 2.6% for α, D, β and β-α. C. A. R.

Iodinated pyrrole derivatives and their behavior with nitric acid. A. PIERONI AND DINO NOCENTINI. *Gazz. chim. ital.* **55**, 348-61(1925).—In prep. the I compds. described a general method was developed. The compd. to be iodinated, generally the bi-CO₂H compd., was dissolved in a large excess of concd. Na₂CO₃. To the clear cold soln. the calcd. amt. of 1.0 *N* I-KI was added. The mono-I derivs. remain in soln. while the small amts. of di-I derivs. formed are inso. and are sepd. by filtration. The mono-I compd. is then sepd. by adding AcOH or dil. H₂SO₄. The di-I derivs. are pptd. at once on adding the calcd. amt. of I₂. The I compds. thus obtained are recrystd. from MeOH or EtOH. 18 g. α,β-dimethylpyrrole-α,β-dicarboxylic acid + 2 g. Na₂CO₃ in enough H₂O to give a clear soln. were treated with 46 cc. 1.0 *N* I-KI. The red ppt. of α,β-dimethyl-α,β-diiodopyrrole, crystd. from warm Et₂O, decomps. 65°. 1 g. Et α,β-dimethylpyrrolecarboxylate was dissolved in a little H₂O with 0.8 g. KOH, 150 cc. H₂O was then added and then 10 cc. 1.0 *N* I-KI drop by drop. α,β-Dimethyl-β-

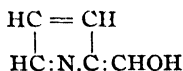

carbethoxy- α -monoiodopyrrole, IC: CMe.C(CO₂Et):CMe.NH, m. 148°, was pptd. and

crystd. from MeOH; this compd. does not react with KOH and when suspended in dil. EtOH gives an intensely red color with FeCl₃ on the H₂O bath. α,α' -Dimethylpyrrole- β,β' -dicarboxylic acid (I) dissolved in excess conc. KOH soln. treated drop by drop with I-KI soln. pptd. α,α' -dimethyl- β,β' -diiodopyrrole (II), m. 134°. 0.5 II in AcOH was treated drop by drop with 3 cc. concd. HNO₃ in AcOH, with cooling. After a few min. the mixt. was poured into H₂O and a yellow-brown amorphous ppt. was formed, from which a definite product could not be isolated. 0.5 g. I in 20 cc. 20% Na₂CO₃ was treated with 5 cc. I-KI. The di-I compd. was filtered off. 20% H₂SO₄ added to the filtrate pptd. α,α' -dimethylpyrrole- β,β' -monoiodocarboxylic acid (III), m. 162° (decompn.). 1 g. III was added gradually to 2-3 cc. concd. HNO₃; after standing the mixt. was thrown into H₂O, the acid was nearly neutralized with Na₂CO₃, and the soln. was extd. with Et₂O. The latter on evapn. gave a compd., silky needles, m. 125°. The di-I₂ ester of I in glacial AcOH with HNO₃ gave a compd. m. 167-8°. These compds. are to be studied further. 0.8 g. phenyl- α,α' -dimethylpyrrole- β,β' -dicarboxylic acid (IV) in a slight excess of concd. KOH with 7 cc. I-KI pptd. phenyl- α,α' -dimethyl- β,β' -diiodopyrrole (V), m. 115°. On nitrating V in AcOH with HNO₃ an amorphous product of unknown constitution was obtained. 2.5 g. IV in excess 20% Na₂CO₃ with the calcd. amt. of I-KI gave phenyl- α,α' -dimethylpyrrole- β,β' -monoiodocarboxylic acid (VI), m. 175°. If VI is purified by dissolving it in Na₂CO₃ and pptg. the cold soln. with dil. H₂SO₄ the product obtained in 190° (decompn.). VI in MeOH with AgNO₃ and a few drops of NH₄OH ppts the Ag salt, which is sol. in excess of NH₄OH. Acetylpyrrole in Na₂CO₃ with the calcd. amt. of I-KI gives 2 products: diiodoacetylpyrrole (VII), m. 168°, and triiodoacetylpyrrole (VIII), m. 202°. VII and VIII were sep'd. by their diverse soly. in EtOH, the latter being the less sol. VII with excess I₂ gives CIII₃ and a trace of VIII. Neither reacts with *p*-bromophenylazoxycarboxamide under normal conditions. 0.4 g. VIII added gradually to 5 cc. concd. HNO₃ gave after neutralizing with Na₂CO₃, extg. with Et₂O, etc., a nitro compd. contg. I. VIII in EtOH-H₂O with Na₂CO₃ reacts with NH₄OH.HCl when boiled 12 hrs. under a condenser. On dilg. the soln. with H₂O and evapg. the EtOH a cryst. compd., m. 172° (decompn.) was obtained. 5 g. IV was added gradually to 30 cc. concd. HNO₃ with cooling; after 15 mins. the mixt. was poured on ice and H₂O was added gradually. Phenyl- α,α' -dimethyl- β,β' -dinilropyrrole, m. 205°, sep'd. α,α' -Dimethylpyrrole- β,β' -dicarboxylic acid on nitration gave a product, m. 115°, of unknown constitution. E. J. W.

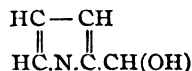

The constitution of pyrrolealdehyde. G. RASTELLI AND A. MINGOZZI. *Gazz. chim. ital.* **55**, 549-51(1925).—Pyrrolealdehyde (I) is unusual in that it is stable in air and does not give the characteristic reactions of aldehydes such as that with benzenesulfohydroxamic acid, while its *N*-Me deriv. is oxidizable by air and gives the characteristic reactions. For these and other reasons a constitution is assigned to I that is quite different from that of the common pyrrole derivs. The 3 formulas considered were II, III and IV, of which III is the most probable. The constitution of I was studied spectro-

(II)

(III)

(IV)

graphically. Pyrrole (Hartley, Dobbie, *J. Chem. Soc.* **81**, I, 929(1902)) and the aldehyde group (Stewart and Baly, *J. Chem. Soc.*, **89**, I, 489(1899)) both show a continuous absorption spectrum and so if I is a true aldehyde it should show a continuous spectrum. Likewise the group N.C.C: in IV would not have a discontinuous spectrum, while that

of the hydroxymethylene group in III is discontinuous. The data conform with formula III and indicate that II and III are in equil. with the equil. well over toward the side of III.

E. J. WITZEMANN

An acridine synthesis from 4,5-benzocoumarandione and aniline. KARL SAFTIEN. *Ber.* **58B**, 1958-60(1925); cf. Fries and Pusch. *C. A.* **19**, 2046.—From 0.01 mol. 4,5-benzocoumarandione (I) heated 15 sec. to boiling in 0.05 mol. PhNH₂ and, after cooling, poured into an excess of dil. HCl is obtained almost quant. 2-hydroxynaphthoyl-1-formanilide anil, HOC₁₀H₆C(:NPh)CONHPh, light yellow, m. around 175°, 2 g. of which, boiled 15 sec. in 10 cc. Ac₂O, gives 1.4 g. 4,5-benzocoumarandione 3-anil, red, m. 182°, quite stable towards aq. NaOH, decompd. by boiling AcOH. 7,8-Benzocacridine-9-carboxylic acid, obtained in 75% yield from 0.01 mol. I boiled 1 hr. in 50 cc. AcOE

with 0.02 mol. PhNH_2 , yellow, m. 284° , easily sol. in alkalis and soda, sol. in concd. H_2SO_4 with yellow color but no fluorescence, loses CO_2 above its m. p. and gives β -chrysidine, m. 131° . **1,2,7,8-Dibenzoacridine-9-carboxylic acid**, from **I** and $2\text{-C}_{10}\text{H}_7\text{NH}_2$ in 85% yield, m. 260° , changing into the acridine, m. 216° . **2-Methoxy-7,8-benzoacridine-9-carboxylic acid**, from $p\text{-MeOC}_6\text{H}_4\text{NH}_2$, yellow, m. 286° (decompn.), forming **2-methoxy-7,8-benzoacridine**, yellowish white, m. 157° . **2-Acetamido-7,8-benzoacridine-9-carboxylic acid**, from $p\text{-AcNHC}_6\text{H}_4\text{NH}_2$, dark yellow, m. 292° , losing CO_2 and forming the acridine, m. 275° (Ullmann, *Friedlander* 6, 461, gives 255°). C. A. R.

Catalysts for the synthesis of indoles according to Fischer. A. KORACZYNSKI AND L. KIERZEK. *Gazz. chim. ital* 55, 361-9 (1925). -After having detd. that PhNHNH_2 decomps. at 150° in the presence of small amts. of Ni, Co or Cu powder and of salts like CoCl_2 , NiCl_2 , CrCl_3 and UCl_6 , K. and K. extended their expts. to derivs. of PhNHNH_2 (mainly phenylhydrazones). Fischer synthesized derivs. of indole by decompn. of phenylhydrazones by fusion with ZnCl_2 or heating with HCl . K. and K. have found that Ni, Co and Cu powder and CoCl_2 , NiCl_2 and many other salts catalyze the same decompn. Arbusov (*C. A.* 4, 3218) observed that this reaction is brought about by Cu halides. K. and K. have studied the action of NiCl_2 especially and compared its action with that of ZnCl_2 and CuCl_2 . The interpretation of this reaction given by Reddell (*C. A.* 6, 1597) and Hollins (*C. A.* 16, 2862) is not considered satisfactory, while that of G. and R. Robinson (*C. A.* 12, 2313, 18, 2161) is simpler and satisfactory. The p -substituted phenylhydrazones do not give rise to indoles but undergo a profound decompn. This conforms with results of Bamberger and Sternicki (*Ber* 25, 1307 (1893)) and of Bltz and Sieden (*Ann* 324, 310 (1902)). PhNHNH_2 was heated to $150\text{--}70^\circ$ with 10% of its wt. of anhyd. NiCl_2 , CoCl_2 and ZnCl_2 and powd. Cu, Fe, Ni, Co, Zn, Al, W, Ti, U and Mo. NH_3 was formed and in the distillate C_6H_6 , PhNH_2 and tar were found. The metals were less active in this decompn. than the salts and also showed a graded effect. The decompn. of the phenylhydrazones of MeCOPh , EtClO and MeCOEt was accomplished with 2% NiCl_2 at 230° and gave 2-phenyl-, 2-methyl- and 2,3-dimethylindole in yields of 60-65%. These bases were treated with an equimol. amt. of picryl chloride + the calcd. amt. of Na_2CO_3 and refluxed on a H_2O bath. After 0.5 hr. they were filtered and on standing sepd. **picryl-2-methylindole**, red needles, m. 110° , and **picryl-2,3-dimethylindole**, red, m. $133\text{--}4^\circ$. 5 g. PhNHNH_2 + 7 g. $p\text{-MeOC}_6\text{H}_4\text{COMe}$ (Cheron and Zemanos, *Compt rend* 133, 742 (1900)), heated 5 min. sepd. on cooling ***p*-methoxyacetophenone phenylhydrazone (I)**, m. 142° , decmps. in light and air. 9 g. **I** + 0.1 g. NiCl_2 were heated 0.5 hr. at $230\text{--}40^\circ$ and dissolved in C_6H_6 , treated with animal C filtered and on standing sepd. **2-*p*-methoxyphenylindole**, m. $228\text{--}9^\circ$. ***p*-Methoxyacetophenone *p*-bromophenylhydrazone**, m. 154° , was prepd. like **I** and when heated with NiCl_2 decompd. profoundly at $154\text{--}60^\circ$. **Acetophenone *p*-methoxyphenylhydrazone**, b_{16-20} $180\text{--}90^\circ$, m. $63\text{--}4^\circ$, on heating with NiCl_2 gives **2-phenyl-5-methoxyindole**. ***p*-Methoxyacetophenone *p*-methoxyphenylhydrazone**, m. $162\text{--}3^\circ$, heated with 4% NiCl_2 at 170° gives NH_3 and **2-*p*-methoxyphenyl-5-methoxyindole**, browns 204° , m. $213\text{--}4^\circ$. 5 g. $p\text{-HOCC}_6\text{H}_4\text{CMe:NNHPh}$ + 0.1 g. NiCl_2 heated at 240° and extd. with Et_2O in a Soxhlet extractor gave **2-*p*-hydroxyphenylindole (II)**, m. 70° . 1.73 g. **II** + 2 g. CO(NHPh)_2 were boiled in dry $\text{C}_6\text{H}_5\text{N}$ for 2 hrs. The mixt. thrown into H_2O sepd. an amorphous compd., $\text{C}_{17}\text{H}_{20}\text{N}_2\text{O}_2$, m. 65° . 13 g. enanthal phenylhydrazone + 0.15 g. Ni + 0.15 g. NiCl_2 were heated at $220\text{--}30^\circ$ for 30 mins. From this ***8*-pentylindole** was sepd. by a method that is described; its *picrate* was obtained, m. $91\text{--}2^\circ$. ***p*-Hydroxydibromoacetophenone *p*-bromophenylhydrazone**, m. 180° , undergoes profound decompn. when heated with Ni.

E. J. WITZEMANN

New azo combinations with diacetosuccinic ester and the Bülow synthesis of substituted pyrazoles. C. BÜLOW AND K. BAUR. *Ber.* 58B, 1926-32 (1925); cf. *Ber.* 33, 262 (1900); Dimroth, *C. A.* 3, 439. -- ***Di-Et [acetyl-*p*-phenylenediamine-azo]diacetosuccinate***, $\text{RN:NCAc(CO}_2\text{Et)CHAcCO}_2\text{Et}$ (**I**, $\text{R} = \text{AcNHC}_6\text{H}_4$), from diazotized $p\text{-AcNHC}_6\text{H}_4\text{NH}_2$ in HCl with $(\text{CHAcCO}_2\text{Et})_2$ and NaOAc in cold aq. alc., m. 134° , does not give the Bülow reaction, is easily converted by long standing in alc., by boiling in dil. alc. or AcOH or by fusion into ***di-Et 5-methyl-1-[*p*-acetylaminophenyl]pyrazole-3,4-dicarboxylate*** (best prepd. by treating the original coupling mixt. directly with steam), m. 158° , which is hydrolyzed by boiling alc. KOH to the free acid, m. 264° (decompn.), can be titrated very accurately, is not pptd. by AcOH from aq. solns. of the *di-K* salt; the ***1-p*-aminophenyl acid**, from the above ester with 1:1 HCl , m. 276° (decompn.), is distinctly amphoteric; although it forms no solid HCl salt, its suspensions in mineral acids yield clear diazo solns. (**II**) which under suitable conditions can be coupled with keto-enol desmotropes of the type of $\text{AcCH}_2\text{CO}_2\text{Et}$, yielding with $\text{AcCH}_2\text{CO}_2\text{Et}$ itself ***Et[5-methylpyrazole-3,4-dicarboxy-1-*p*-aniline-azo]acetoacetate***,

EtO₂CCHAcN:NC₆H₄N $\begin{cases} N = CCO_2H \\ CMe: CCO_2H \end{cases}$, yellow, m. 215-6° (decompn.), and with

AcCH₂CONHPh the corresponding *acetoacetanilide*, decomps. about 266°, which cannot be titrated and whose C₆H₅N salt in H₂O gives ppts with metallic salts. *Di-Et [5-methylpyrazole-3,4-dicarboxy-1-p-aniline-azo]acetonedicarboxylate*, from II and CO-(CH₂CO₂Et)₂, yellow hydrated leaflets (1 or 2H₂O), m. anhyd. around 140°, yields with alkalis needles, decomp. 265°, contg. 49.12, 49.23% C, 3.89% H and 13.40% N. *p*-AcNHC₆H₄NH₂, m. 195-6°, is obtained in 57% yield from 25.2 g. com. distd. (C₆H₄-NH₂)₂ and 14 g. Ac₂O in CHCl₃ in the cold. *Di-Et [N-monoacetylbenzidine-azo]diacetosuccinate*, m. 163° (decompn.), does not give the Bulow reaction. *Di-Et 5-methyl-1-[p-acetylaminodiphenyl]pyrazole-3,4-dicarboxylate*, m. 168°; free acid, m. 285° (decompn.); *K II salt*, decomp. 325°; *di-K salt*; *1-p-aminodiphenyl acid*, m. 287° (decompn.). *Tetra-Et diacetosuccinate[azobenzidine-azo]diacetosuccinate*, from tetrazotized (C₆H₄NH₂)₂ and (CHAcCO₂Et)₂, faintly yellow, m. 152° (decompn.), does not give the Bulow reaction. *Tetra-Et 1-p-di-phenylbis-[5-methylpyrazole-3,4-dicarboxylate]*, m. 141°; free acid, m. 302° (decompn.); *tetra-K salt*; *di-K salt*, does not change up to 350°. C. A. R.

New syntheses of nitrogenated heterocyclic nuclei. I. Pyrazolecarboxylic acids through dehydrocondensation of the aldehyde hydrazones with acetoacetic ester. GAETANO MINUNNI WITH G. LAZZARINI AND S. D'URSO. *Gazz. chim. ital.* **55**, 502-39 (1925).—The 1st twenty pages of this paper are devoted to a systematic review of all the general methods that have been devised for the synthesis of pyrazolecarboxylic acids (I), under 19 headings. A practical method of general application was lacking until it was learned that aldehyde hydrazones and AcCH₂CO₂Et interact at 120-35° with ZnCl₂ to give pyrazolecarboxylic acids. Gas is evolved during the reaction. Since ZnCl₂ has a pronounced resinifying action on the hydrazones it is necessary to reduce the time of heating as much as possible. To 10 g. of dry hydrazone in a 50-cc. flask provided with an air condenser is added a slight excess of AcCH₂CO₂Et and then 0.1-0.2 g. fused ZnCl₂. The mass is heated in a paraffin bath with agitation. When gas evolution is complete an equal vol. of EtOH is added to the warm oily mass. A mass of crystals is formed which is filtered off after some hrs. The ester of I obtained is recrystd. from EtOH. The best yields are obtained when the hydrazone resists the resinifying action of ZnCl₂ and when the ester formed is little sol. in EtOH. When these conditions do not exist the oily mass is poured into EtOH as before, and the EtOH is distd. The residue is distd. with steam to remove unchanged AcCH₂CO₂Et. The ester of I is then extd. with hot ligroin or 50% EtOH. On cooling, these solns. sep. a little tar which is filtered off. Later the cryst. ester of I seps. When the compd. cannot be isolated in this way the crude product is sapond. at once, in the hope of obtaining free I in the cryst. form, by heating with 10% EtOH-KOH or with concd. H₂SO₄. The alk. soln. is dild. with H₂O, filtered and extd. with Et₂O to eliminate the impurities. This soln. is acidified with dil. HCl and the free acid (I) pptd. is crystd. from a suitable solvent. If H₂SO₄ was used, the mixt. is poured into much H₂O and the I pptd. is filtered off, dissolved in Na₂CO₃, filtered, repptd. with dil. HCl and crystd. as before. The following compds. were prepd. in this way. From the phenylhydrazone of enanthal. *3-enanthyl-1-phenyl-5-methylpyrazole-4-carboxylic acids*, m. 100-1°; Et ester, uncrystallizable. From BzH *3-phenyl*, m. 194°; Et ester, m. 105°. From *m*-O₂NC₆H₄CHO, *3-[m-nitrophenyl]*, m. 207-8°; Et ester C₁₉H₁₇O₄N₃, m. 105.5-6.5°. *3-[p-nitro]isomer*, m. 209.5-210°; Et ester, C₁₉H₁₇O₄N₃, m. 107-8°. From *o*-HOOC₆H₄CHO *1-phenyl-3-[o-hydroxyphenyl]-5-methylpyrazole-4-carboxylic acid lactone* or *1-phenyl-5-methylpyrazocoumarin*, m. 182-3°, giving in KOH-EtOH *1-phenyl-3-[o-hydroxyphenyl]-5-methylpyrazole-4-carboxylic acid*, m. 160° (decompn.). From *p*-MeOC₆H₄CHO, *3-anisyl*, m. 177-8°; Et ester, C₂₀H₂₀O₄N₂, m. 88-9°. From piperonal, *3-piperonyl*, m. 203-4°; Et ester, m. 97-8°. From *p*-MeC₆H₄NHN:CHPh, *1-[p-tolyl]-3-phenyl-5-methylpyrazole-4-carboxylic acid*, m. 202-3°; Et ester, C₂₀H₂₀O₄N₂, m. 94-5°. The results given in this paper and those obtained with BzCH₂CO₂Et (described in a subsequent paper) show that the dehydrocondensation of the β-ketonic acid esters with the hydrazones of aromatic aldehydes gives a new general convenient method for the synthesis of a large no. of I. The compds. formed in this way are identical with those obtained by the action of NH₂NH₂ on alkylidene- and benzylidene-acetoacetic esters and isomers of these that NH₂NH₂ also gives with acylacetoacetic esters. But these two reactions discovered by Knorr (*Ann.* **238**, 137 (1887)); Knorr and Duden, *Ber.* **26**, 111 (1893)) depend on almost inaccessible compds. while the compds. used in the new synthesis are easily available. The resinifying action of ZnCl₂ in certain instances is a difficulty that remains to be overcome.

E. J. WITZEMANN

Thiazoles. VIII. The condensation of *o*-aminophenyl mercaptan and *o*-aminophenyl disulfide with acid chlorides, anhydrides and esters. M. T. BOGERT AND ARTHUR STULL. *J. Am. Chem. Soc.* **48**, 248-54 (1926); cf. *C. A.* **20**, 386.—*Et oxanilate o-disulfide*, light yellow, m. 104° (all m. ps. cor.), in 68% yield from (CO₂Et)₂ and (o-H₂NC₆H₄)₂S₂; coned. NH₄OH gives 93% of *oxanilamide o-disulfide*, m. 240° (decompn.); PhNH₂ at 150° gives 49% of *oxanilide o-disulfide*, m. 229-30°. Reduction by EtONa gives benzothiazole-2-carboxylic acid in 60% yield. *o*-H₂NC₆H₄SH and (COCl)₂ give bis-2,2'-benzothiazolyl (oxalamidothiophenol), m. 300.5°. *Succinanilic acid o-disulfide*, sinters 155-8°, m. 167.8°, 28% yield. *Glutaranilic acid deriv.*, m. 155-6°, decomp. 160-1° (91% yield). *Camphoranilic acid deriv.*, greenish yellow, m. 229° (40% yield). *Malcanilic acid deriv.*, yellow, m. 200-1° (97% yield). *o*-Phthalimido-phenyl *o-disulfide*, m. 219° (85% yield), it is hydrolyzed by 10% EtOH-KOH on warming. 2,2'-[*p*-Phenylene]bisbenzothiazole, m. 263°, in 62% yield from *o*-H₂NC₆H₄SH and *p*-C₆H₄(COCl)₂. *Pyromucylanilide o-disulfide*, yellow, m. 160.5° (66% yield); reduction gives 82% of 2-*α*-furylbenzothiazole, also obtained in 75% yield from *o*-H₂NC₆H₄SH and pyromucyl chloride. *α*-Thenoylanilide *o-disulfide*, pale yellow, m. 154° (67% yield); reduction gives 56% of 2-*α*-thienylbenzothiazole, m. 99.5°, whose tea-rose or geranium odor is more pronounced than that of 2-phenylbenzothiazole itself.

C. J. WEST

Reactions of the formamidines. XI. The 2-thio-4-thiazolidones. F. B. DAINES AND SILAS I. DAVIS. *Kansas Univ. Sci. Bull.* **15**, 265-70 (1924); cf. *C. A.* **17**, 543; **14**, 1667.—The 2-thio-4-thiazolidones have been found to react with substituted formamidines to form derivs. of the type $\text{S.CS.NH.CO.C} \begin{smallmatrix} \text{---} \\ \text{---} \end{smallmatrix} \text{CHNHR}$ and with aldehydes to

from compds. of the type $\text{S.CS.NH.CO.C} \begin{smallmatrix} \text{---} \\ \text{---} \end{smallmatrix} \text{CHR}$ When 2-thio-4-thiazolidone (I) (cf.

Nencki, *J. prakt. Chem.* [2] **16**, 4 (1877)) and diphenylformamidine (II) in kerosene are heated at 120° for 1 hr and recrystd. from alc., yellow needles of 2-thio-5-anilino-methylene-4-thiazolidone (III), S.CS.NH.CO.C. CHNHPh, are obtained in 46% yield, m.

248° and sol. in NaOH. 2-Thio-3-phenyl-4-thiazolidone (IV) (from NH₄ phenyldithiocarbonate and ClCH₂CO₂Na) and II gave 2-thio-3-phenyl-5-anilino-methylene-4-thiazolidone (V), m. 247°. V is decompd by alc. KOH and forms a hydrazone(?), m. 215°. 2-Thio-3-phenyl-5-*α*-naphthylaminomethylene-4-thiazolidone from the correspondingly substituted thiazolidone and formamidine in 36% yield, m. 279°. 2-Thio-3-*p*-tolyl-5-anilino-4-thiazolidone, prep'd. like IV, m. 235°. Di-*p*-amylformamidine and IV gave 2-thio-3-phenyl-5-*p*-methoxyanilinomethylene-4-thiazolidone, m. 158-60°. When treated with PhCH₂Cl in dil. NaOH, the benzaldehyde and cinnamaldehyde condensation products of I gave 2-benzylthio-5-benzal-4-thiazolidone, S.C(SCH₂Ph).N.CO.C:CHPh,

m. 123°, and 2-benzylthio-5-cinnamal-4-thiazolidone, m. 143°, in 96% and 88% yields, resp. When III is heated with EtI in alc. KOH 2-ethylthio-5-anilinomethylene-4-thiazolidone, S.C(SEt).N.CO.C:CHNHPh, m. 175°, is obtained; III and PhCH₂Cl

in NaOH gave quant. 2-benzylthio-5-anilinomethylene-4-thiazolidone, m. 221-3°.

N. A. LANGE

Strophanthin. VIII. The carbonyl group of strophanthidin. W. A. JACOBS AND A. M. COLLINS. *J. Biol. Chem.* **65**, 491-505 (1925).—Dissolved in *N* NaOH, dild. to 0.3 *N*, and oxidized at 10° with KMnO₄ (slightly > 1 mol. O₂), dihydrostrophanthidin (I) (*C. A.* **19**, 1281) yields with dil. HCl a lactone acid, C₂₃H₃₄O₇ (II), platelets with 2H₂O, froths 132-3°. [α]_D²⁸ 47° in MeOH; on further oxidation with KMnO₄ it does not yield a keto acid like that obtained by analogous reactions from strophanthidin (III) itself (cf. *C. A.* **18**, 2169). II may also be prep'd. from I and KMnO₄ in MeAc; in coned. HCl at 0° for 20 min. followed by diln. with H₂O and filtration from an amorphous impurity, it slowly deposits the dilactone C₂₃H₃₂O₈ (IV), leaflets with 0.5 H₂O, m. 232-4°, [α]_D²⁸ 84° in MeOH, the 2nd lactone group sapon. with greater difficulty than the 1st. By the same method the lactone acid C₂₃H₃₂O₇ (V), previously considered C₂₂H₃₀O₇ (*C. A.* **18**, 2169) and prep'd. from III and KMnO₄ in MeAc, yields a dilactone C₂₃H₃₀O₈ (VI), crystals with 1 H₂O, m. 235-6°, [α]_D²⁷ 100° in MeOH, reduces Tollens soln. in dil. C₆H₅N. IV and VI were thus obtained instead of analogs of dianhydrostrophanthidin (VII). Pseudostrophanthidin (VIII) (*loc. cit.*) is scarcely acted on in MeAc by KMnO₄ but in HOAc with CrO₃ soln. prep'd. according to Kiliani (*C. A.* **7**, 1717) it yielded on diln. a keto dilactone C₂₃H₂₈O₈ (IX), m. 285° (decompn.).

$[\alpha]_D^{28} +93^\circ$ in C_6H_5N , also formed from VI; *oxime*, m. with gas evolution above 285° . With CrO_3 by the above method VII yields chiefly a *dilactone* $C_{23}H_{26}O_4$ (X), m. $253-4^\circ$, $[\alpha]_D^{28} -178^\circ$ in $CHCl_3$, reduces Tollens soln.; also shows an active H with $MeMgI$, probably owing to the grouping $\text{C}=\text{C}-\text{CH}_2-\text{CO}$, freed from the very small amt. of

accompanying *lactone acid* $C_{23}H_{28}O_5$ (XI) by digestion with dil. aq. NH_3 . XI m. 268° (gas evolution), $[\alpha]_D^{25} -100^\circ$, also obtained as chief product (with no X), from VII and $KMnO_4$ in MeAc, leaflets with 1 H_2O , m. $272-4^\circ$ (gas evolution), $[\alpha]_D^{25} -102^\circ$ in alc. Boiled in aq. alc. 0.05 N NaOH for 2 hrs., freed from alc., and acidified, X gives the dibasic acid $C_{23}H_{30}O_6$, m. $249-51^\circ$ (gas evolution) (sometimes $242-3^\circ$). In AcOH with Pd and II X yields the *tetrahydro lactone* $C_{23}H_{30}O_4$, m. $275-7^\circ$, $[\alpha]_D^{28} 3^\circ$ in $CHCl_3$, slowly reduces Tollens reagent in dil. C_6H_5N , showing the unsatd. lactone grouping to be unreduced; only 1 of the lactone groups is sapond. under the conditions used for X; the other is opened by N NaOH. With very carefully purified X and carefully prepd. Pd black a 3rd mol. of H_2 could slowly be introduced with reduction of the double bond originally present in III, the resulting *hexahydro lactone* $C_{23}H_{32}O_4$, m. $265-7^\circ$ to a turbid liquid, which clears somewhat higher; $[\alpha]_D^{25} 14^\circ$ in $CHCl_3$, does not reduce Tollens soln.; 1 lactone group sapons. readily. It is thus shown that in the oxidation of these compds. the point of attack is not the double bonds, but the CO group, which occurs as an aldehyde. In VII this may react in the oxidic or lactol form. VIII is the lactol form of III, since no oxime is formed. With CrO_3 it is oxidized directly to the lactone IX, a sec.-OH being also oxidized to CO, and since IX is also formed from VI, an OH previously considered tertiary in III must now be treated as sec. CrO_3 and $KMnO_4$ are thus shown to oxidize specifically the lactol and aldehydic forms, resp.

M. HEIDELBERGER

Complex salts of quinoline, metallic chlorides, water and hydrogen chloride. WM. M. DEHN. *J. Am. Chem. Soc.* **48**, 275-7(1926).—Quinoline(Q), metallic salts, HCl and H_2O may form, according to the literature, 15 different types of complex salts, although the types are not all definitely established. In the effort to obtain salts of the type $2Q.MX_n.2HX.2H_2O$, 1 mol. equiv. or more of Q in concd. HCl was treated with 1 mol. equiv. of the metallic chloride, the mixt. heated until a clear soln. was obtained and then allowed to cryst. *Diquinoline hydrochloride-CuCl_2*, dichromate-colored, softens 90° , m. 110° ; *CoCl_2*, dark blue, m. 118° (the dried salt softens 125° and m. 155°); *NiCl_2*, yellow, coloring green at 125° , does not m. 250° ; *CaCl_2*, very sol. needles; *ZnCl_2*, m. 119° ; *SrCl_2*, hygroscopic needles, does not m. 250° . *Q hydrochloride-PbCl_2*, silvery needles, does not m. 250° ; *FeCl_3* gives a similar salt. *Di-Q hydrochloride-CdCl_2*, needles, does not m. 250° . *Q hydrochloride-AsCl_3*, with $2H_2O$, softens 120° , m. 145° . The *SbCl_3* compd., m. 198° ; *BiCl_3* compd., m. 212° . The *MnCl_2* compd., with 1 H_2O , needles, does not m. 250° .

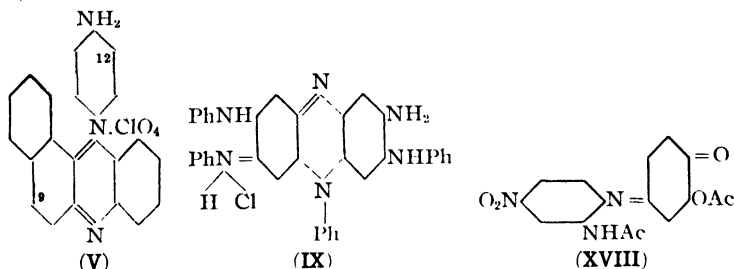

C. J. WEST

Complex salts of quinoline, mercuric halides, water and hydrohalogen acids. WM. M. DEHN. *J. Am. Chem. Soc.* **48**, 277-82(1926); cf. preceding abstr.—Complex double salts involving halogen, quinoline (Q) and Hg conform to 6 types for Cl, 8 types for Br and 5 types for I. Their prepn. involves definite conditions and is largely influenced by the sp. affinities of the resp. halides. Type I, *Q.HgCl_2*, m. 223.5° ; *Q.HgBr_2*, m. 204° ; *Q.HgI_2*, m. 168° . Type II, *Q.HBr.HgBr_2*, m. 121° , obtained by dehydration of the dihydrate; *Q.HI.HgI_2*, yellow, m. 147° (heating with H_2O gives $2Q.HI.HgI_2$ and HgI_2). Type IV, *Q.HBr.HgBr_2.2H_2O*, softens 100° , m. 118° , becomes opaque in the air. Type V, *2Q.HgCl_2*, best prepd. by heating $HgCl_2$ and more than 2 mol. equivs. of Q on the H_2O bath, also from *Q.HgCl_2* and Q or from $HgCl$ and excess Q, softens 145° , m. above 200° , decomp. during the heating into *Q.HgCl_2* and Q. *2Q.HgBr_2*, softens 145° , m. 185° ; *2Q.HgI_2*, light yellow, softens 145° , m. 154° . Type VI, *2Q.HgCl_2.HCl*, m. 142° , prepd. from *Q.HgCl_2* and *Q.HCl* in EtOH or MeCN, from compds. of type VIII or IX with Q; *2Q.HgBr_2.HBr*, m. 147° ; *2Q.HgI_2.HI*, yellow, m. 106° . Type VII, *2Q.HCl.HgCl_2*, softens 95° , m. 130° , from 2 mols. *Q.HCl* and 1 of $HgCl_2$ in anhyd. solvents or by dehydrating compds. of type VIII; about 2 g. dissolves in 1 l. of boiling Me_2CO ; hot H_2O gives a compd. of type I; concd. HCl gives a compd. of type VIII; *2Q.HBr.HgBr_2*, soften at 70° and m. 118° ; *2QHI.HgI_2*, yellow, softens 110° , m. 160° ; it melts in hot H_2O and gives a mixt. of *QHI.HgI_2* and unchanged material. Type VIII, *2Q.HgCl_2.2HCl.2H_2O*, m. 91° ; the *bromide* softens below 100° , m. 120° ; the *iodide* could not be prepd. Type IX, *2QHCl.3HgCl_2*, m. 160° , from the components in hot MeCN; boiling H_2O gives a compd. of type I; concd. HCl, type VIII; *Q.HCl*, type VII; Q, type VI; HCl in Me_2CO , type VII; *2QHBr.3HgBr_2*, m. 145° .

C. J. WEST

Quinone-imide dyes. VIII. The 18th isomer of rosinduline. F. KEHRMANN

AND L. LISTWA. *Helvetica Chim. Acta* **8**, 655-61 (1925); cf. *C. A.* **19**, 644.—Of the 26 possible mono- NH_2 derivs. of phenylnaphthophenazonium (I) and isophenylnaphthophenazonium (II) the 18th, an NH_2 deriv. of II, has now been prepd. $\beta\text{-C}_{10}\text{H}_8(\text{:O})_2$ (III) and 2,4'-($\text{H}_2\text{NC}_6\text{H}_4$) $_2\text{NH}\cdot\text{H}_2\text{SO}_4$ in a little dil. H_2SO_4 at room temp. for 4 days, filtered from a brown by-product, and pptd. with HClO_4 , give a mixt. in which the II deriv. preponderates. Dried and heated on the H_2O bath with Ac_2O , pptd. with HClO_4 and fractionally recrystd. from alc. the more sol. *acetylisorosinduline-18 perchlorate*, $\text{C}_{24}\text{H}_{17}\text{ON}_3\cdot\text{HClO}_4$ (IV), forms orange-red needles, sol. in H_2SO_4 with dark brown-red color, gives a blue deriv. when heated with PhNH_2 and $\text{PhNH}_2\cdot\text{HCl}$, whereas the I analog gives a red product; *chloroplatinate*, brick-red. Heated 1 hr. on the H_2O bath with 50% H_2SO_4 , IV yields *isorosinduline-18 perchlorate* (V) after neutralizing and adding NaClO_4 , dark red-brown, sol. in H_2SO_4 with a dirty red color; the diacid salts give orange solns. Since a 19th isomer could not be prepd. directly from III and 2,3'-($\text{H}_2\text{NC}_6\text{H}_4$) $_2\text{NH}$ (VI), the 4-AcNH deriv. of III and VI 2HCl were heated in alc. 24 hrs. at 40-50°,

depositing *9-acetamino-12-aminophenylnaphthophenazonium chloride* (VII) brown; *chloroplatinate*, dark red; *perchlorate*, brown-red, sol. in H_2SO_4 with a brownish violet-red color; the salts give a blue color with PhNH_2 and $\text{PhNH}_2\cdot\text{HCl}$. The mother liquors from the chloride contain a small amt. of the I deriv. VII, let stand 12 hrs. dissolved in just enough of a soln. of 2 vols. H_2SO_4 to 1 H_2O , dild. with a little H_2O , and warmed on the H_2O bath until dark green and a test turns blue on further dildn. and neutralization, then dild. with 5 vols. H_2O and neutralized with solid Na_2CO_3 , gives the *9,12-diamino sulfate*, dark blue; *chloride* (VIII), difficultly sol. in H_2O with a dull violet color; *perchlorate*, dark violet crystals from alc.; *nitrate*, blue-black. Solns. of the diacid salts are green, while the color in concd. H_2SO_4 is dark brown-red. Ac_2O and VIII at room temp. give the *9-amino-12-acetamino chloride*, dark green, sol. in H_2O with a violet-blue color; *perchlorate*, sol. in H_2SO_4 with a brown-red color. Salts of the last 3 compds., heated on the H_2O bath with Ac_2O and NaOAc give the *9,12-diacetamino deriv.*; *perchlorate*, dark brick-red needles from alc., sol. in H_2O with an orange-red color, in H_2SO_4 with a dark bluish red shade. IX. **Total synthesis of induline 6 B.** F. KEHRMANN AND (MISS) I. STANOYEVITCH *Ibid* 661-3 —1,2,4,5-(PhNH) $_2\text{C}_6\text{H}_2(\text{:O})_2$ and 1,3,4,6-(PhNH) $_2\text{C}_6\text{H}_2(\text{NH}_2)_2\cdot 2\text{HCl}$, boiled in alc. until the initially red soln. becomes dark blue, form an *induline* (IX) with a golden reflex, sol. in H_2SO_4 with a violet color; boiled with 2 parts $\text{PhNH}_2\cdot\text{HCl}$ and 10 of PhNH_2 , the -NH_2 is replaced by PhNH- and NH_4Cl sublimes, induline 6 B sepg. on cooling, as bronze crystals identical with that prepd. by K. and Klopfenstein (*C. A.* **18**, 1288). X. **Amino azines derived from naphthalene.** F. KEHRMANN AND J. SAFAR. *Ibid* 668-76. With the consent of Panizzone-Favre, who recently found (*Researches on the synthesis of 2-nitro-1,4-naphthoquinone*, Milan) 4,1,2-AcNHC $_{10}\text{H}_6(\text{NH}_2)_2$ (X) to be oxidizable by the air and to condense with phenanthrenequinone to form an azine (XI), the study of XI was continued (with C. T. HUGUENIN) and the reactions of X were studied in detail. XI, heated on the H_2O bath with H_2SO_4 (2:1), gives the red *sulfate* of the orange *aminoazine*, m. 309-16°, the yellow solns. of which in org. solvents fluoresce bluish green and which is sol. in H_2SO_4 with a red-violet color. In 50% HOAc at the b. p. for a moment X and (PhCO) $_2$ give the *acetaminoazine* $\text{C}_{26}\text{H}_{19}\text{ON}_3$, yellow, m. 245°, sol. with a faint blue-violet fluorescence, in H_2SO_4 with a fuchsin-red color; with Me_2SO_4 it gives an azonium base, analyzed as the orange *chloroplatinate*; *aminoazine sulfate*, red; *base*, yellow, m. 245° (its solns. fluoresce blue-green); the triacid salt in concd. H_2SO_4 is fuchsin-red, a little H_2O giving the olive-green color of the diacid salt, much H_2O the eosin-red of the mono-salt. When a current of air is passed for several days through a soln. of X in 125 parts 50% HOAc contg. a few drops dil. aq. FeCl_3 the sym. (XII) and unsym. (XIII) azines are formed, tan-yellow microcrystals, insol. in H_2O and org. solvents, sol. in H_2SO_4 with a dark blue color; after

sapong, and drying the mixt., boiling alc. extd. a small amt. of what was probably the amino deriv. of **XIII**, dark brown crystals, while most of the residue, apparently the amine corresponding to **XII**, formed brick-red crystals from PhNO_2 ; with weakly fuming H_2SO_4 it gives the violet color of the tetra-acid salt, changing through green to the fuchsin-red of the di-salt on addn. of water and to the bluish tan of the mono-salt on partial neutralization. The mixt. of **XII** and **XIII** was also synthesized from **X** in 50% HOAc and the 4-AcNH deriv. of **III** in HOAc on the H_2O bath. **X** and the 3-AcNH deriv. of **III** gave a similar mixt. from which the more sol. *diacetamino-azine* $\text{C}_{14}\text{H}_{18}\text{O}_2\text{N}_4$ (assumed to be the unsym. compd.) was extd. in small amt. by boiling alc., yellow, sol. in fuming H_2SO_4 with a dark blue color; the *sym. analog*, yellow, is sol. in fuming H_2SO_4 with a brown-violet color; the *diamino compds.* obtained on sapon. are orange and dark orange, resp. The colors of the various salts are given. **X** and 1,2,1,5-(HO) $_2\text{C}_6\text{H}_2$ -(O) $_2$ gave the *acetaminodihydroxy-azine*, $\text{C}_{14}\text{H}_{13}\text{O}_5\text{N}_4$, pale yellow, turns reddish at 100° , sol. with a yellow color in dil. NaOH, gives a fuchsin-red with H_2SO_4 . **X** and the 4-HO deriv. of **III** give a mixt. of the sym. and unsym. azines, dark orange; sapon. with boiling alc. HCl gives an insol. *amino-azine di-HCl salt*, $\text{C}_{10}\text{H}_7\text{ON}_2 \cdot 2\text{HCl}$, dark orange; the more sol. *hydro- isomer* crystals, on concn. of the alc. filtrate. **XI. Derivatives of phenazine.** F. KEHRMANN AND E. HAENNY. *Ibid* 676–85. An attempted continuation of the prepn. of analogs of industrially important anthraquinone derivs (cf. K and Cherpillod, *C. A.* 19, 643). 3,4-(H_2N) $_2\text{C}_6\text{H}_3\text{NO}_2$ and 3,4-(O) $_2\text{C}_6\text{H}_3\text{OH}$ in HOAc for 12 hrs. yield at least 5 different substances. The ppt. (**A**) is sep'd and the remainder pptd. by diln. and neutralization (**B**). 3.3 g. **A** in 40 cc. Ac_2O , treated with ZnCl_2 until dissolved, deposits 3-nitro-6-acetoxyphenazine (**XIV**), lemon-yellow, m. 211° ; after several hrs. in 2:1 H_2SO_4 , diln. and partial neutralization yield the dark orange 3-nitro-6-hydroxyphenazine, sol. in alkalis with a mauve color, in H_2SO_4 the color in thin layers is green, violet in thicker layers, and purplish red in deep layers. When **XIV** is dissolved in 50 parts hot HOAc, pptd. in finely divided form by rapid cooling, and treated with Zn dust until intensely violet, diln. with a little H_2O ppts. the *dihydro deriv.*, violet black needles; if the Zn is added until the color is red and then enough H_2O to dissolve the $\text{Zn}(\text{OAc})_2$ the violet color returns and a little Zn is again added until an intense red develops, when excess NaHCO_3 is quickly dropped in and 3-amino-6-acetoxyphenazine ppts., orange, with a greenish metallic luster, m. 201° , gives the same color reactions as 3- $\text{H}_2\text{NC}_6\text{H}_3(\text{N})_2\text{C}_6\text{H}_4$; if aq. NH_3 is used above instead of NaHCO_3 the crude 3-amino-6-hydroxy deriv. seps. exposed to the air in dil. HCl soln. the HCl salt ppts.; this with Ac_2O and ZnCl_2 gives 3-acetamino-6-acetoxyphenazine (**XV**), purified by extn. with boiling C_2H_5 , yellow, m. 258° , sol. in H_2SO_4 with a yellow-brown color and elimination of the OAc group; boiled withalc. HCl it gives the *HCl salt*, red, of 3- $\text{H}_2\text{NC}_6\text{H}_3(\text{N})_2\text{C}_6\text{H}_3\text{OH}$ (–6) (**XVI**) (Nietzki and Almenraeder, *Ber.* 28, 2963 (1895)); *chloroplatinate*, blood-red. Heated in H_2O with addn. of NaOH until dissolved, **XV** yields with HOAc 3-acetamino-6-hydroxyphenazine, straw-yellow, turns brick-red at 110° , sol. in dil. alkalis with a red-orange color. **XVI** and 10% aq. H_2SO_4 at $210\text{--}20^\circ$ for 2 hrs. give 3,6-dihydroxyphenazine, yellow, sol. in dil. alkalis with an intense yellow color, sol. in H_2SO_4 with a yellowish red color, purified through the *diacetate*, yellow, m. 224° . **B**, acetylated as was **A**, but with as little Ac_2O as possible, deposits what is undoubtedly 3-nitro-7-acetoxyphenazine (**XVIi**), yellow, m. $224\text{--}7^\circ$; 3-nitro-7-hydroxyphenazine, red-brown, sol. in alkalis with a Bordeaux-red color, shows dichroism in H_2SO_4 ; *dihydro deriv.*, violet-black; 3-acetamino-7-acetoxyphenazine, yellow, m. 249° , sol. in alc. with green fluorescence; 3-acetamino-7-hydroxyphenazine, brown, with a slight brassy reflex, red-orange in H_2O or dil. alkalis, dichroic in H_2SO_4 ; 3-amino-7-hydroxyphenazine, red-brown, slightly sol. in H_2O with a red color, dichroic in H_2SO_4 . The filtrate from **XVII** is dild. with H_2O and the ppt. dried, extd. with PhH , and gray flocks pptd. with a little petroleum ether. The filtrate, evapd. in the air, gives a mixt. of **XVII** and brown crystals, sep'd. mech., the latter finally yielding an *acetaminoacetoxyanilide*, $\text{C}_{16}\text{H}_{13}\text{O}_6\text{N}_4$, probably **XVIII**, yellow, m. 206° , sol. in H_2SO_4 with a brown-red color; *aminohydroxyanilide*, brick-red, sol. in dil. alkalis with a blood-red, in H_2SO_4 with yellow color, yields with $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$ an *azine*, sol. in H_2SO_4 with a green color.

M. HEIDELBERGER

Alkaloids of colombo root. III. Constitution of columbamine and of jatrorrhizine. ERNST SPÄTH AND ROBERT DUSCHINSKY. *Ber.* 58B, 1939–46 (1925); cf. *C. A.* 17, 1239.—Assuming that Feist's detn. of the no. of MeO groups (4) in his tetrahydrocolumbamine (**I**) (*C. A.* 13, 1453) is correct, I should be identical with tetrahydrocolumbamine (**II**) and as a matter of fact the m. ps. of the 2 bases and of some of their derivs. agree perfectly; F. himself has recently communicated to S. and D. that his supposed columbamine consisted chiefly of palmatine and it is suggested that the name columbamine be temporarily abandoned and held in reserve for any new alkaloid which may later be

nitroveratryldihydroisoquinoline, $\text{O}_2\text{N}(\text{MeO})_2\text{C}_6\text{H}_3\text{CH}_2\text{C}:\text{N}.\text{CH}_2.\text{CH}_2.\text{C}_6\text{H}_4$ (II), with

various dehydrating agents (P_2O_5 , POCl_3 , PCl_5 , Al_2Cl_6). On the other hand, homoveratroylphenylethylamine (III), m. 111.5° , produces veratryldihydroisoquinoline (IV), m. 138° , on heating with POCl_3 , in xylene (sulfate of IV, m. 124° , *N*-methosulfate, m. 240° , methiodide, m. 198°), nitration of which gives 2,4,5- $\text{O}_2\text{N}(\text{MeO})_2\text{C}_6\text{H}_3\text{CH}_2\text{C}:\text{N}.\text{CH}_2.\text{CH}_2.\text{C}_6\text{H}_4$ (V), which on oxidation goes over to *s*-*o*-nitroveratrumic acid,

m. 192° . Homoveratroylpiperonylethylamine (VI), m. 136° , gives a HCl salt m. 207° , methiodide m. 225° , methochloride m. 137° . Nitration of 3,4-dihydro-6,7-methylene-dioxy-1-veratryliso-quinoline (VII), gives a mixt. of isomeric nitro derivs. which cannot be sepd. Homoveratrumyl chloride and piperonylethylamine give homoveratroylpiperonylethanamide, $(\text{MeO})_2\text{C}_6\text{H}_3\text{CH}_2\text{CONHCH}_2\text{CH}(\text{OH})\text{C}_6\text{H}_3\text{O}_2\text{CH}_2$ (VIII), m. 91° , which with POCl_3 goes over to veratryldihydronorhydrastinine (IX), m. 130° . By nitration of IX, is obtained a mononitro deriv., yellow, m. 228° ; HCl salt, m. 244° ; *N*-methosulfate, m. 210° . S. T.

The preparation of pure digitonin, and the accompanying saponins of digitals seed. A. WINDAUS. *Z. physiol. Chem.* **150**, 205–10 (1925).—Com. digitonin contains 70–80% digitonin, 10–20% gitonin and 5–15% of other saponins. Purification by Kiliani's method gives a beautifully cryst. product but this is contaminated with gitonin. A sepn. may be effected by pptn. from H_2O by means of Et_2O ; the digitonin comes down much more rapidly than the gitonin, and 2 or 3 pptns. give a pure product. Oxidation of the crude digitogenin with CrO_3 gave a diketone, $\text{C}_{26}\text{H}_{35}\text{O}_4$, m. 228° (dioxime, decomps. $250\text{--}4^\circ$), and a monoketone, $\text{C}_{26}\text{H}_{35}\text{O}_3$, m. $204\text{--}5^\circ$. A. W. DEX

Salicin. I. Exceptional rotations of the halotetraacetyl derivatives of salicin. A new synthesis of salicin. ALFONS KUNZ. *J. Am. Chem. Soc.* **48**, 262–8 (1926).—Acetylation of salicin with Ac_2O and $\text{C}_6\text{H}_5\text{N}$ gives practically quant. the penta-Ac deriv. (I), m. 130° ; MeONa gives pure salicin. I (50 g.) in 150 cc. CHCl_3 with 100 cc. 40% HBr gives 82% of tetraacetylsalicin bromide, $[\alpha]_D^{24.5} 42.7^\circ$ (0.9717 g. in 100 cc. CHCl_3); Ag_2CO_3 suspension in dil. Me_2CO gives 71% of tetraacetylsalicin (II), m. 126° , $[\alpha]_D^{25} -15.9^\circ$ (0.9949 g. in 100 cc. CHCl_3). Acetylation gives I. II and PCl_5 gives the chloride, m. 160° , $[\alpha]_D^{23.5} 11.5^\circ$ (1.0014 g. in 100 cc. CHCl_3). I and HI in CHCl_3 -chloride, m. 160° , $[\alpha]_D^{23.5} 11.5^\circ$ (1.0014 g. in 100 cc. CHCl_3). I and HI in CHCl_3 -chloride give 66% of II iodide. Reduction of either the chloride, bromide or iodide with Zn in 50% AcOH gives 76% of tetraacetyl- β -*o*-cresylglucoside, m. 141° , $[\alpha]_D^{25} -25.4^\circ$, which is deacetylated to β -*o*-cresylglucoside, the yield from the original salicin being about 60%, thus furnishing the best method for prep. this compd. Br in abs. CHCl_3 at -20° , exposed to sunlight converts this into tetraacetylsalicin bromide, from which salicin may be obtained in the usual manner, thus giving a synthesis of salicin from β -*o*-cresyl glucoside. The halogen derivs. show *d*-rotation in contrast with the *l*-rotation of the other compds.; the increase in rotation with increasing halogen wt. is exceptional, since this is a known property of the α -glucosides. C. J. WEST

The brasilin and hematoxylin question. IV. Methoxychromonols and the Schall-Dralle degradation product of brasilin. P. PFEIFFER, H. OBERLIN AND E. KONERMANN. *Ber.* **58B**, 1947–58 (1925); cf. *C. A.* **18**, 2158.—Preliminary attempts to demethylate 7-methoxychromonol (I) to the 7-HO compd. (II) (the Schall-Dralle degradation product of brasilin) having failed (on account of lack of sufficient material), 7-methoxychromone was demethylated with fuming HBr to the 7-HO compd. (III), whose Ac deriv. was hydrogenated catalytically by the Willstätter method to 7-aceloxychromanone (IV), which was easily hydrolyzed to the 7-hydroxychromanone (V). It was not found possible, however, to nitrosate V either by the alk. or the acid method with AmONO , nor could it be condensed with *p*- $\text{ONC}_6\text{H}_4\text{NMe}_2$. With $\text{MeOC}_6\text{H}_4\text{CHO}$, it readily condenses to the 3-4'-methoxybenzal deriv. (VI), which, again, however, does not give the expected II on ozonization. After these failures, recourse was again had to demethylation of I, working with larger amts. and using fuming HBr instead of HI, and from 0.07 g. I boiled 2.5 hrs. with HBr was obtained 0.04 g. II, identical with the S.-D. degradation product of brasilin. The 6- and 8-isomers of I were synthesized by condensing *p*- and *o*- $\text{HOC}_6\text{H}_4\text{OMe}$, resp., with $\text{ClCH}_2\text{CH}_2\text{CO}_2\text{H}$, nitrosating the resulting chromanones with AmONO and KOEt in alc. and boiling the isonitroso compds. a short time in dil. $\text{H}_2\text{SO}_4\text{-AcOH}$. 7,8-Dimethoxychromonol (VII), which bears to hematoxylin the same relation which II does to brasilin, was similarly synthesized from 2,3-($\text{MeO})_2\text{-C}_6\text{H}_3\text{OH}$. III (yield, 76%), m. $215\text{--}6^\circ$; acetate, m. $94\text{--}5^\circ$ (yield, 74%). IV (yield, 74%), m. $94\text{--}5^\circ$. V (yield, 91%), almost colorless, with a tinge of brown, m. $147\text{--}8^\circ$, easily sol. in dil. alkalis and aq. NH_4OH , converted by alk. Me_2SO_4 into the Me ether,

m. 53.5-4.7°; *oxime*, crystals with 1 H₂O, m. 97-8°, easily sol. in alkalis and aq. NH₄OH. VI (yield, 73% crude or 41% pure product), green-yellow, m. 215-6°, easily sol. in dil. alkalis and aq. NH₄OH, shows deep red halochromism in concd. H₂SO₄; *acetate* (yield quant.), light yellow, m. 123-4°, sol. in concd. H₂SO₄ with deep red color. II, faintly brownish, m. 270-1° (decompn.). β -[*p*-Methoxyphenoxy]propionic acid (0.5 g. from 2 g. *p*-MeOC₆H₄OH), m. 110.5°, easily sol. in aq. alkalis, gives with PCl₅ in boiling C₆H₆ and then, after cooling, with AlCl₃ 71%, 6-methoxychromanone, m. 49°; *oxime*, m. 119°; easily sol. in aq. alkalis; *semicarbazone*, m. 229.5°; 3-isonitroso deriv. (1.1 g. from 2 g. of the chromanone), faintly yellow, m. 145°, easily sol. in aq. alkalis and NH₄OH, 0.1 g. of this yields 0.05-0.06 g. 6-methoxychromanol, yellowish, m. 170°, sol. in hot aq. alkalis with faintly yellow color and reprecipitated by acids in a white form gradually becoming yellowish. β -[*o*-Methoxyphenoxy]propionic acid (10.5-2.5 g. from 25 g. guaiacol), m. 135-6°, easily sol. in aq. alkalis; 2 g. yields 0.65 g. 8-methoxychromanone, m. 89.5°, whose *oxime*, m. 145-6°, *semicarbazone*, m. 232°, and 3-isonitroso deriv. (0.8 g. from 2.5 g. of the chromanone), yellowish, m. 163° (decompn.). 8-Methoxychromanol, faintly yellowish, m. 182-3°, partially subliming, sol. in hot aq. alkalis with faint yellow color. β -[*o,m*-Dimethoxyphenoxy]propionic acid (3.5 g. from 10 g. (MeO)₂C₆H₃OH), m. 101.5°; 10 g. yields 3.1-3.8 g. 7,8-dimethoxychromanone, m. 101°, insol. in aq. alkalis, whose 3-isonitroso deriv. (0.35 g. from 1 g. of the chromanone), faintly yellowish, decomps. 170°, easily sol. in aq. NH₄OH, yields 64% of VII, m. 174-5° (decompn.), sol. in hot aq. alkalis and NH₄OH with yellow color. C. A. R.

Efficiency of photosynthesis by *Chlorella*. E. Q. ADAMS. *J. Am. Chem. Soc.* **48**, 292-4 (1926).—The structure of chlorophyll *a* and *b* is such that it would be expected to absorb simultaneously 2 quanta of red light. The energy of the 4 quanta so absorbed, 174.4 cal./mol., is sufficient to cause the chlorophyll to pass through a cycle of 4 reactions, the outcome of which is the conversion of 1 mol. of CO₂ and 3 mols. of H₂O into 2 of H₂O₂ and 1 of HCHO, for which 171.0 cal./mol. is required. Since 6 mols. of HCHO are required to produce 1 mol. of glucose, whose heat of combustion (dissolved) is 674 cal./mol., the max. possible efficiency of glucose production is 61.4%; Warburg and Negelein (*C. A.* **18**, 1316) found for the mean efficiency of *Chlorella*, using red light, 59%, and the highest single value, 63.5%. The formula for *b*-chlorophyll, C₅₅H₇₂O₆N₄Mg, agrees within the usual limits of org. quant. analysis with the formula C₅₅H₇₀O₆N₄Mg, assigned to it by Willstätter. C. J. WEST

Dissociation constants of plant nucleotides and nucleosides and their relation to nucleic acid structure. P. A. LEVENE AND H. S. SIMMS. *J. Biol. Chem.* **65**, 519-34 (1925).—In addn. to the acid and basic groups of the pyrimidine and purine "bases" there should be 8 ionizable H atoms on the PO₄ groups in yeast nucleic acid according to Jones' original structure, 6 according to his later views, and only 5 according to L.'s formula. Since the total no. of ionizable groups could not be detd. by direct titration, the no. of groups which should dissociate within a given *p*_H range was calcd. for each of the structures, and the actual values were then detd. exptly. Numerous tables and curves expressing the results are given. In the nucleotides the *p*_K' values for the PO₄ groups are a little lower than the 1st and 2nd *p*_K values of H₃PO₄, i. e., 2.0 and 6.8. Except in the case of the guanine derivs. the NH₂ groups are alike and have consts. close to that of PhNH₂ (*p*_K = 4.7), while the consts. of the 1st OH groups, except in the cytosine derivs., are like that of PhOH (*p*_K = 10). In the case of nucleic acid the results are expressed in terms of the *p*₀' values, where the G' values are found by treating the titration data as if the solns. contained equiv. amts. of monobasic acids. Methods of calcn. are given. It is shown that for thymus nucleic acid there is only 1 *p*₀ value in the range *p*_H 4.5 to 9, which agrees with L.'s structure, since only differences in the "sec."-PO₄ groups are involved. The data of Thomas and Dox (*C. A.* **19**, 1854) are also held to support this structure, rather than that of J. as T. and D. had concluded. The values obtained with yeast nucleic acid were unsatisfactory. M. H.

Bromolecithins. I. Fractionation of brominated soy-bean lecithins. P. A. LEVENE AND I. P. ROLF. *J. Biol. Chem.* **65**, 545-9 (1925).—Soy-bean lecithin, purified according to C. A. **19**, 1130, in 10 parts gasoline (b. 40-50°), and Br₂ in 5 parts gasoline, at a temp. < -5° on addn. of Br₂ until no longer decolorized, pptd. a crude bromolecithin mixt. (I). A portion was boiled 8 hrs. with 10 parts 10% HCl and the dried acids were extd. with gasoline. The insol. portion sepd. hexabromostearic acid from hot MeOH, while the filtrate yielded the tetra-Br acid, purified through the Pb salt. I, taken up in Et₂O and let stand at 0°, deposited a light yellow amorphous powder, corresponding to a hexabromostearylstearyllecithin, coalesces on warming to room temp. The Et₂O-sol. fraction, pptd. by gasoline and again purified as above, gave a shiny, buttery mass corresponding roughly to a tetrabromostearylstearyllecithin. The nature

of the satd. acids will be studied further. The results lend support to the view that the lecithins as isolated from animal and plant tissues are mixts. of individual lecithins each contg. 2 fatty acids.

M. HEIDELBERGER

A non-tetrahedral C atom in crystals of pentaerythritol (HUGGINS, HENDRICKS) 2. The relation between sweet taste and constitution of chemical compounds (HERZOG) 11A. Physical properties of some isomeric ethylenes (ERRERA, HENRI) 3.

Die Methoden der Organischen Chemie. Vol. II. 3rd ed. revised and enlarged. Edited by J. Houben. Leipzig: G. Thieme. 1431 pp. Price, paper. R. M. 75; bound, R. M. 85. Cf. C. A. 19, 2345.

MACARDLE, DONALD W.: **The Use of Solvents in Synthetic Organic Chemistry.** New York. D. Van Nostrand Co. 224 pp. \$3.50.

Acetylenation of organic substances. L. G. BOURGOIN. U. S. 1,567,785, Dec. 29. Fatty substances and glycerol or other substances susceptible of combination with C_2H_2 are treated with CaC_2 which is decomposed with H_2O or steam to produce C_2H_2 for the reaction, *e. g.*, in the formation of an elec. insulating material for molding.

Absolute propyl alcohol. J. A. STEFFENS. U. S. 1,568,349, Jan. 5. A ternary mixt. is formed by adding to aq. propyl alc. a third liquid such as C_6H_6 which is miscible with the $PrOH$ but substantially immiscible with H_2O . The mixt. is subjected to distn. to evolve a ternary const.-b. p. mixt. and leave abs. $PrOH$ as a residue. A portion of the evolved distillate is refluxed to the top of the rectifier and the remainder of the distillate is condensed and allowed to sep. into 2 layers. The upper layer, which is the richer in the added liquid, is returned to liquid undergoing distn. and rectified $PrOH$ from the lower layer is also returned.

Lead alkyls. B. MEAD. U. S. 1,567,159, Dec. 29. Pb is placed in contact with an aq. emulsion of EtI or other alkyl halide (which may contain casein) and the reaction mass thus formed is subjected to reduction, *e. g.*, by electrolysis, to produce, finally, Et_4Pb or the like.

Urea. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAP. Norw. 39,744, June 29, 1925. Urea is produced from NH_3 and CO_2 by passing CO_2 over ammoniates at an increased temp.

Finely crystalline urea. WARGOENS AKTIEBOLAG. Swed. 59,319, Aug. 19, 1925. A soln. of urea is evapd. to at most 10% of water. The mass obtained is molded into blocks and after solidification may be crushed.

FRANK P. UNDERHILL

The crystallization and specific rotation of ovalbumin and an attempt to crystallize lactalbumin. C. W. CHAPMAN. *Can. Chem. Met.* 9, 268-70 (1925).—By adjusting the final pH (by means of "10% acetic acid") to between 4.7 and 5.1 (approx. the isoelec. point) a good crop of crystals of ovalbumin may be readily obtained. The crystals are centrifuged, dissolved in the least quantity of distd. water, any coagulum is filtered off, and satd. $(NH_4)_2SO_4$ added till a permanent cloudiness appears. The yield in each case was about 80%. The purified crystals have a sp. rotation of -30.68° . Lactalbumin did not crystallize when subjected to the same procedure. E. G. R. A.

Action of emulsin on amygdalin. L. ROSENTHALER. *Arch. Pharm.* 263, 563-6 (1925).—The cleavage of amygdalin by the action of emulsin is believed to take place in the following stages: amygdalin ($C_{20}H_{27}NO_{11}$) + H_2O = mandelic nitril glucoside ($C_{14}H_{17}NO_6$) + glucose ($C_6H_{12}O_6$) and $C_{14}H_{17}NO_6$ + H_2O = C_6H_5CHO + HCN + $C_6H_{12}O_6$. W. O. E.

Vitali test as applied to a decomposing dog stomach. TH. SABALITSCHKA AND W. BOLDT. *Pharm. Ztg.* 70, 1650-1 (1925).—A case is cited in which a substance, yielding by the Vitali test a red-violet color, was isolated from a decomposing dog stomach. W. O. E.

The laws governing monomolecular reactions (enzyme reactions—catalytic re-

actions). L. AMBARD. *J. chim. phys.* **22**, 402-12(1925).—Sugar inversion by acids and other catalytic reactions do not obey the simple kinetic formula postulated by the mass action law, because the latter takes into account only the no. of collisions between the enzyme and the substrate mols. $\varphi = k(C_1C_2)$, where φ is the reaction velocity, C_1 the catalyst concn., C_2 the substrate concn. The other detg. and hitherto neglected factors are: (1) the concn. of the activator (anion or cation), (2) the adsorption of the enzyme by the substrate, which introduces C_2 once more into the equation, (3) the elementary reaction velocity. The latter is defined as the no. of substrate mols. transformed by the enzyme in the time unit and is based on the assumption that this transformation requires time and that therefore only a limited no. of elementary reactions can take place, when C_1 is very low as compared with C_2 ; hence the lack of proportionality between φ and C_2 at high C_2 , when C_1 is kept const. All peculiar features of many catalytic reactions are explained by this theory, which is supported by exptl. proof. It was found by expts. not recorded in the paper that the role of the activator in the amylolysis of starch or glycogen is to fix the amylase on the substrate. The activator is therefore called amboceptor. The curve representing the relation between φ and the concn. of the amboceptor has a max. followed by a flat portion, the position of the max. varying with the nature of the activating anion. The max. is interpreted as the point at which the entire catalyst is fixed on the substrate. The role of adsorption in catalysis was established by a defixation expt. Rice starch which has acquired a high amylolytic power by centrifuging with NaCl-saliva was treated with glycogen solns. of different concns. The amylase was detached from the starch by the glycogen in proportion to the concn. of the latter, the defixation curve presenting all features of an adsorption curve. The hydrolysis of glycogen of different concns. with the same amt. of amylase-activator showed that the reaction velocity was proportional to the product of C_2 and the defixation power characteristic for this concn. In the acid hydrolysis of sugars H^+ is at the same time amboceptor and catalyst. The satu. phenomenon which is peculiar to enzyme reactions because of the eventual fixation of the entire catalyst is not encountered in this case. φ can grow continuously with C_2 since very likely only a small proportion of the available H^+ is actually engaged in catalysis and new H^+ can be gradually supplied by progressive dissociation. M. J.

The relation between sweet taste and constitution of chemical compounds. WALTHER HERZOG. *Oesterr. Chem.-Ztg* **28**, 143-6, 152 4(1925).—A review of the literature with numerous references. H. believes that we are far from understanding the relations especially in the aromatic series. MARY JACOBSEN.

The blood pigment and some porphyrins. HANS FISCHER. *Z. angew. Chem.* **38**, 981-8(1925).—A review of the research in this field and of the chem. and biol. relations established up to the present time. Especial reference is made to porphyrinuria, which is considered to be a reversion to an atavistic type of pigment formation. The presence of coproporphyrin in yeasts and the feathers of turaceous and the conversion by yeasts of blood pigment to ooporphyrin suggest that coproporphyrin is an evolutionary stage of hemin and that both may be formed from some common precursor, probably ooporphyrin. The great likeness of yeast metabolism to that of higher animals on one hand and their great plant-like assimilating power on the other make yeasts appear as the link between the animal and plant kingdom. Chlorophyll, therefore, like hemin may be produced from coproporphyrin or its precursor, ooporphyrin. M. J.

Experiments on contraction of white connective tissue fibers. C. J. TIDMARSH AND JOHN TAIT. *Quart. J. Exptl. Physiol.* **15**, 367-76(1925).—Heat contraction of mouse-tail tendon produces localized swellings. When contraction is at its height the whole tendon is swollen. In solns. of $CaCl_2$, the higher the concn. of salt the lower the temp. at which the tendon contracts; with 48% $CaCl_2$ the tendon contracts at 0° . Similar effects are obtained in $BaCl_2$ solns.; 36% $BaCl_2$ gives contraction at 38° . In both cases the relation between concn. and temp. is linear. FRANCES KRASNOW.

The influence of oxygen tension upon the biological oxidation process. R. J. HAMBURGER AND A. V. SZENT-GYÖRGYI. *Biochem. Z.* **157**, 298-302(1925); cf. *C. A.* **19**, 3497.—Finely minced and washed diaphragm muscle of swine is placed in a phosphate soln. in a special respirometer. *p*-Phenylenediamine is then added, and the rate of O consumption measured. The rate is independent of O pressure. W. D. L.

Purification of oxynitrile and some of its properties. E. NORDEFELDT. *Biochem. Z.* **159**, 1-35(1925); cf. *C. A.* **17**, 3515.—The enzyme in emulsin which causes the formation of active mandelonitrile from $PhCHO$ and HCN is called oxynitrile. It is best prepd. by an alk. extn. of mandels, followed by an acid extn. of the alk. ext. The acid soln. is then pptd. with Me_2CO and the ppt. used as the enzyme prepn. Dialysis, fractional pptn. with acids, adsorption on alumina, colloidal $Fe(OH)_3$, and kaolin,

and pptn. with $\text{Pb}(\text{OAc})_2$ and tannin are all tried as means of purification of the enzyme. It is not inactivated by toluene, by acids to $p_H = 3.0$ and by alkalis to $p_H = 11.0$, but is destroyed by heat at about 75° . The kinetics of the enzymic reaction is studied.

W. D. LANGLEY

Influence of neutral salts upon the acid binding of gelatin. J. CSAPÓ. *Biochem. Z.* 159, 53-7(1925).—To det. whether NaCl and other Na salts repress the hydrolysis of protein- Cl , the p_H of gelatin solns. contg. known amts. of HCl and Na salts were compared with the p_H of these same amts. of acid and salt in H_2O alone. The difference in c_H between the 2 solns. gave the amt. of bound acid. Several salts of Na , e. g., iodide and nitrate, increased the acid-binding power of the gelatin, while the sulfate decreased it. In 0.02 to $0.03\ N$ H_2SO_4 , the acid binding of the gelatin was less than in HCl of the same concn. Cations increased the acid binding in the order $\text{K} < \text{Na} < \text{Ba} < \text{Ca}$.

W. D. L.

The proteins of blood. I. H. HUECK. *Biochem. Z.* 159, 89-106(1925). H. seeks to det. whether or not the various proteins of blood are really different. The protein in native serum is higher in concn. by 0.026% than in defibrinated serum. If serum stands for several hrs., the protein concns. at different levels in the soln. are not the same. The n of expressed serum increases with time. No such variation is observed with whole blood serum and plasma serum. The detns. of albumin and globulin may not give abs. but only relative values.

W. D. L.

Nephelometric investigation of fermentative protein hydrolysis. V. KINETICS of peptic hydrolysis of serum albumin. P. RONA AND H. KLEINMANN. *Biochem. Z.* 159, 146-74(1925); cf. *C. A.* 19, 3101.—The k value for the velocity of the action of pepsin on serum albumin indicates the reaction to be of the second order. It is proportional to the concn. of enzyme as well as to that of the substrate. On the acid side of the optimum H-ion concn., k decreases, probably because of some effect of the acidity upon the enzyme. Between $\text{H-ion} = 4.17 \times 10^{-3}$ and 1.7×10^{-3} the rate of hydrolysis is nearly directly proportional to the H-ion . No effect due to the presence of hydrolysis products could be detd. The temp. coeff. for the reaction is 1.9, measured from 30 to 40° .

W. D. L.

The pK' of the Henderson-Hasselbalch equation for hydron concentration of serum. G. E. CULLEN, H. R. KEELER AND H. W. ROBINSON. *J. col. Chem.* 66, 301-22(1925).—The soln., $0.01\ N$ HCl in $0.09\ N$ KCl , should preferably be used as a standard of reference in detg. the hydron concn. of blood or serum with the value of 2.04 at 38° . The temp. difference between 38° and 20° is $+0.01\ p_H$. pK'_{38° detd. on 15 pathol. human sera gives an av. of 6.095 (CO_2 soly. coeffs. of Bohr and Boek used in the calcn.). pK'_{20° for the same sera is 6.183 . The values for pK' for dog sera agree with those for human sera. There is no evidence that the nature of the disease, possible salt content variation, protein variation, or p_H itself significantly affect these values. The temp. coeff. for pK' is -0.005 per 1° . The temp. coeff. for the CO_2 -combining capacity of human sepd. serum at const. $[\text{H}_2\text{CO}_3]$ and at const. p_H are calcd. as $(d[\text{BHC}_3]/dt^\circ)/[n_2\text{CO}_3] = -0.10\ \text{mM per } 1^\circ$ and $(d[\text{BHCO}_3]/dt^\circ)/p_H = -0.14\ \text{mM per } 1^\circ$.

A. P. LOTHROP

The solubility of tertiary calcium phosphate in cerebrospinal fluid. L. EMMETT HOLT, JR. *J. Biol. Chem.* 66, 23-8(1925); cf. *C. A.* 19, 3275.— $\text{Ca}_3(\text{PO}_4)_2$ is far less sol. in cerebrospinal fluid than in blood serum but both are normally supersatd. with it. The greater soly. in blood serum and the higher concns. of Ca and PO_4 ions can be explained on the basis of the electrostatic effects of the polyvalent protein ions of the serum which diminish the activity coeffs. of the inorg. ions there, thus making it possible for a high stoichiometric concn. to coexist with a comparatively low activity.

A. P. LOTHROP

Electroendosmosis through mammalian serous membranes. II. Comparison of hydrogen-ion reversal points with acetate and with citrate-phosphate buffers. S. MUND. *J. Gen. Physiol.* 9, 73-9(1925); cf. *C. A.* 19, 1435.—The H-ion reversal point values with acetate buffer are about $0.25\ p_H$ higher (more alk.) for fat membranes and almost $0.5\ p_H$ higher for lean membranes than those for citrate-phosphate buffers. The acetate values probably correspond more closely to the true H-ion reversal points. The reversal points are characteristic for a given membrane and species of mammal. No difference between living and postmortem membranes was noted in respect of the H-ion reversal point.

CHAS. H. RICHARDSON

The inactivation of trypsin by X-rays. H. CLARK AND J. H. NORTHROP. *J. Gen. Physiol.* 9, 87-96(1925).—The effect of soft X-rays on trypsin in soln. parallels the effect brought about by spontaneous heat inactivation. The free or active pepsin is entirely or largely affected. Under radiation of const. intensity, inactivation follows the simple

exponential law, indicating a unimol. reaction. The amt. of ionization required to inactivate trypsin to half value in these expts. and in those of Hussey and Thompson (*C. A.* 17, 2590, 3681) who employed β rays from Ra, B and C, are in close agreement. The effect is a function of ionization. Inactivation of free pepsin seems to result from elec. neutralization of the pepsin ion by the addn. of one electron. C. H. R.

Some consequences of the theory of membrane equilibria. D. I. HITCHCOCK. *J. Gen. Physiol.* 9, 97-109(1925).—"In applying Donnan's theory of membrane equil. to systems where the non-diffusible ion is furnished by a weak acid, base or ampholyte, certain new relations have been derived. Equations have been deduced which give the ion ratio and the apparent osmotic pressure as functions of the concn. and ionization const. of the weak electrolyte, and of the H-ion concn. in its soln. The conditions for max. values of these 2 properties have been formulated. It is pointed out that the progressive addn. of acid to a system contg. a non-diffusible weak base should not cause the value of the membrane potential to rise, pass through a max., and fall, but should only cause it to diminish. It is shown that the theory predicts slight differences in the effect of salts on the ion ratio in such systems, the effect increasing with the valence of the cation." C. H. R.

Bioluminescence. J. W. FRENCH. *Nature* 115, 944(1925).--While unrolling some insulating tape F. observed along the line of sepn. a band of green light, which he shows is not due to any elec. charge which might have been imparted during the initial winding of the roll. The phenomenon is undoubtedly one of mechanical luminescence and the emission of light is apparently the result of the sudden extension and possible rupture of the tenacious, viscous threads into which the adhesive material is drawn. F. suggests that the light of a bioluminous character emitted, for example by the glow-worm, may be the result of a sudden longitudinal extension of the gelatinous luminous cells or their granular contents. FLORENCE N. SCHOTT

Elasticity of protein solutions. HANS NETTER. *Arch. ges. Physiol.* (Pflüger's) 210, 450-61(1925).—The viscosity anomalies of certain protein solns. in zones of lower pressure are brought into connection with their tendency to gelatinize and their dependence upon ionic and non-conducting media is considered. G. H. S.

Further studies on living membranes. ERNST WERTHEIMER. *Arch. ges. Physiol.* (Pflüger's) 210, 527-44(1925); cf. *C. A.* 19, 854.—The opposing surfaces of living membranes are the sites of different ion concns. Thus in the frog skin the H-ion concn. in the vicinity of the outer side is greater than that on the inner side. In the frog lung the region of the inner side is more acid than that of the outer side. The Cl-ion concn. shows in each case the reverse relation. If H or OH ions are introduced into the membrane sac by the injection of moderately rapidly permeating acids or bases, the H ions pass toward the outside, the OH ions toward the inner side. In other words, for H and OH ions under the given conditions there is an irreciprocal permeability. If NaCl is introduced, there occurs, as Cl migrates to the inner side, the previously described irreciprocal permeability for NaCl, *i. e.*, permeability only from outside to within. To dead membranes these observations do not apply. The one-sided concn. of definite ions in the normal membrane, and particularly that observed after the artificial administration of such ions to the membrane, is to be explained as a polarizing ion-concn. change. As for reductions and oxidations, detd. by the elec. structure in the membranes, corresponding to Nathansohn's electrolytic respiration theory, with the living membrane no abs. deductions can be drawn, although it appears that the locus of strongest reduction is definitely on the outer side of the frog skin and on the inner side of the frog lung. There is no reason to think that the opposite sides represent the regions of oxidation. After destruction of the elec. structure through mincing the fermentative reductions are augmented, while those processes dependent upon structure disappear. After the death of the membrane reduction can no longer be detected. G. H. S.

Adsorption of glucose by bovine blood corpuscles. HANS HAUSLER. *Arch. ges. Physiol.* (Pflüger's) 210, 557-60(1925).—There is no qual. difference in the glucose-adsorbing ability of bovine and of human blood cells. But bovine blood cells take up glucose only when the concn. in the surrounding fluid does not exceed 0.5%. With human cells the limiting concn. of the surrounding fluid is higher. The cells behave differently in that human blood corpuscles swell when in a glucose soln., from which they do not adsorb glucose, while bovine corpuscles do not. This argues against the assumption that the mechanism of the inhibition is the same in both instances. G. H. S.

Action of gastric lipase in homologous and heterologous wheys. M. LANDSBERGER. *Z. Kinderheilk.* 39, 665-7(1925).—L. found that splitting of tributyrin by the

gastric lipase of infants proceeds much more quickly in whey from human milk than in that of cow milk, as had been detd. by Davidsohn. Colloidal substances, and not ionic conditions, are responsible for this difference, since in protein-free wheys the process occurs with the same speed. G. H. S.

The enzymic action of plasma. H. v. EULER. *Naturwissenschaften* 13, 938-9 (1925).—E.'s "double affinity theory" (that splitting enzymes have affinity for and bind simultaneously the two cleavage products) is applied to cell plasma. The cleavage products remain attached to the enzymically acting plasma and are for that reason in a highly active state, able to take part in further decompn. or synthetic processes. The action of enzymic plasma, therefore, is not limited to activation of just one particular reaction but rather to that of all reactions in which the primary cleavage products can take part. B. J. C. VAN DER HOEVEN

The high molecular state of proteins and the synthesis of protein-like piperazine derivatives. M. BERGMANN. *Naturwissenschaften* 13, 1045 50(1925).—A lecture, reviewing the present situation and recent work of B., Mückeley and Kann (C. A. 20, 381). B. J. C. VAN DER HOEVEN

Digestive enzymes of an insect. H. S. SWINGLE. *Ohio J. Sci.* 25, 209-18(1925).—Two methods were used: (1) grinding the tissues in 30% glycerol and testing for enzymes macrochemically; (2) testing the contents of the intestinal tract microchemically. Method (1) showed amylase in the salivary gland; maltase, invertase, and lipase in the foregut, gastric ceca, mid gut; trypsin and erepsin in gastric ceca and mid gut; lactase and pepsin were not demonstrable. Method (2) showed amylase, invertase, trypsin and erepsin in contents of the foregut, mid gut and hind gut; maltase and lipase in the contents of foregut and mid gut; lactase and pepsin were not demonstrable. J. J. W.

The effect of certain bases on the action of enzymes. H. HULPIEU. *Univ. of Oklahoma, Studies* No. 21, 22-6(1925).—The effect of various bases (hydroxides of Na, K, Ca, Ba and Sr and atropine) on the activity of pepsin and of 2 amylases was studied, with a view to deducing evidence for the enzymic nature of cell division and other cell phenomena. J. J. WILLAMAN

Collagen (HERZOG, GONELL) 2. Gelatin and collagen (KATZ, GERNGROSS) 2. Application of fluorescence to chemistry, pharmacy and biology (FABRE) 3.

MICHAELIS, L. and PARSONS, T. R.: **Practical Physical and Colloid Chemistry for Students of Medicine and Biology.** Cambridge: W. Heffer & Sons, Ltd. 195 pp. 7s. 6d.

Tabulae Biologicae. Vol. I. Reine und physiologische Physik, physikalische Chemie und biologische Anwendungen. Edited by C. Oppenheimer and L. Pincussen. Berlin: W. Junk. 522 pp. Reviewed in *Ind. Eng. Chem.* 18, 107(1926).

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

Surgical method in the physiology of digestion. Description of the most important operations on the digestive system. W. N. BOLDYREFF. *Ergebnisse Physiol.* 24, 399-444(1925).—The description includes the method of procedure in salivary (parotid, submaxillary and sublingual), esophageal, gastric, pancreatic, Thiry-Vella, colon, bile, Eck's, tracheal and ureteral fistulae in dogs and crop fistula on roosters. The procedure for the extirpation of the pancreas, liver and thyroid is given as well as some operative technic on the brain and spinal cord. H. J. DRUEL, JR.

A simple modification of Folin's urea determination. J. ELLINGHAUS. *Z. physiol. Chem.* 150, 211-4(1925).—The permutite-urease method can be much shortened by detg. 1st the preformed NH_3 , then in a 2nd sample the preformed NH_3 + the NH_3 liberated by urease, and deducting the 1st detn. Another advantage of the modification is that no turbidity results when the Nessler reagent is added. A. W. DOX

Observations on the estimation of the acid elements in the gastric juice. A. LABAT. *Bull. soc. pharm. Bordeaux* 63, 172-7(1925).—L. has compared the results obtained for free HCl and org. acids in the gastric juice, using the clinical method proposed by Tofer-Linossier as modified by Michaelis, with those found by using the more exact method of Braun, known also as the Hehner and Seemann method. These results are presented in tabular form. They show that the Michaelis modification gives figures which accord more closely with those obtained by the Braun method than those obtained by the original Tofer-Linossier method. The adoption of the Michaelis modification is, therefore, recommended for clinical work. A. G. DUMÉZ

Estimation of fat in blood. C. P. STEWART AND A. C. WHITE. *Biochem. J.* 19,

840-4(1925).—Two cc. blood are added to 30 cc. alc.-ether mixt. (3 parts alc. to 1 part ether) in a 50-cc. flask, the mixt. brought to the b. p., cooled, and made up to 50 cc. with alc.-ether. It is mixed, allowed to settle and 25 cc. of the supernatant liquid withdrawn for analysis. The total fatty acids of the blood are estd. by sapon. with NaOH and titrating the excess alkali with acid; the micro-buret described by Rehberg (*C. A.* 19, 2148) is used.

BENJAMIN HARROW

New hydrolysis product from elastin. RUDOLF ENGELAND. *Biochem. J.* 19, 850-2(1925).—Elastin was hydrolyzed with HCl, the product treated with phosphotungstic acid, the ppt. washed with 5% H_2SO_4 , treated with $\text{Pb}(\text{OH})_2$, washed and treated with $\text{Ba}(\text{OH})_2$. The Pb was removed with H_2S , the filtrate concd., boiled with $\text{Cu}(\text{OH})_2$, filtered, the filtrate concd. and treated with MeOH to turbidity. After it had stood several days at 0° the ppt. was washed with ice water, suspended in H_2O and treated with H_2S to remove Cu. In concn. the filtrate gave white needles; they were recrystd. from dil. MeOH. The analysis suggests the formula $\text{C}_{16}\text{H}_{22}\text{O}_6\text{N}_2$; the analysis of the Cu salt ($\text{C}_{16}\text{H}_{22}\text{O}_6\text{N}_2\text{Cu}$), however, suggests a compd. contg. 16 C atoms. E. names the substance *hyphasmine* (from the Greek word, "the tissue").

BENJAMIN HARROW

Observations upon the preparation and standardization of the ovarian hormone. FRANK DICKENS, E. C. DODDS AND SAMSON WRIGHT. *Biochem. J.* 19, 853-9(1925).—The minced tissues (pigs' ovaries) were extd. with twice their wt. of alc., stirred, the mixt. was pressed in a hard press through jean (cotton cloth) and the solid material extd. in a Soxhlet app. with alc. for 6-9 hrs. The alc. exts. were combined and filtered through Chardin papers. The filtrate was evapd. almost to dryness *in vacuo* and the residue taken up with a small quantity of alc. and filtered. On standing, a ppt. of fats and cholesterol sepd., which was removed by filtration. The soln. was again taken down to dryness, the residue dissolved in ether, and twice its vol. of acetone was added. The pptd. lipins were filtered off, and the solid material was again dissolved in ether and reprecipd. with acetone. This process was repeated several times. The filtrates were combined and evapd. to dryness. The residue was dissolved in alc. and some cholesterol removed by freezing. By repeating this process, most of the cholesterol can be removed. The active material is obtained by distg. off the alc. *in vacuo*. Unlike Allen, Doisy, etc. (*C. A.* 17, 3532), neither from the liquor folliculi nor from the human placenta could large yields of the hormone be obtained. The hormone is sol. in alc., ether, acetone and olive oil. It can be heated to 200° without loss of activity but withstands sapon. only to a limited extent. Ovarian exts. were standardized by the method of Allen and Doisy—by detg. the min. quantity which will bring about artificial estrus in ovariectomized animals. Rats were used. The exts., dissolved in olive oil or suspended in weak bicarbonate soln., were injected subcutaneously. If the ext. was active, estrus appeared sometimes after 24 hrs. and usually within 36 hrs. of the time of injection. Administration by mouth proved ineffective. The substance inhibits the blood-sugar reducing action of insulin.

BENJAMIN HARROW

Note on the work of Felix Schmieder "On the efficiency-coefficients of phosphores." S. I. VAVILOV. *Ann. Physik* 78, 112(1925).—Controversy over the interpretation of V's results (cf. Vavilov, *Z. Physik* 32, 236(1925); Schmieder, *C. A.* 20, 18). R. J. H.

Coloration of Negri bodies. D. CAMPANACCI. *Sperimentale* 79, 665-7(1925).—Acid fuchsin in dil. HOAc is used as the 1st stain, followed by "indacocarmine" in satd. aq. picric acid.

M. HEIDELBERGER

Technic for the demonstration of spermatozoa. BERTHOLD MUELLER. *Deut. Z. ges. ger. Med.* 6, 384-91(1925).—When the staining method for identification fails, it is recommended that the suspicious material be well macerated in distd. water for 24 hrs. To prevent bacterial action on the spermatozoa, 1 part of HgCl_2 is added to 4 parts of maceration mixt. This mixt. is centrifuged and the sediment again examd. With the Florence reaction a ppt. is obtained even in a 1 to 35 diln. (water). The air-dried macerated mixt. may be stained according to May-Grünwald, G. Strassmann or with Fe hematoxylin.

FRANCES KRASNOW

Microscopic technic for hair study. HEINZ KOCKEL. *Deut. Z. ges. ger. Med.* 6, 381-3(1925).

FRANCES KRASNOW

Quantitative estimation of minute amounts of urea. J. T. WEARN AND A. N. RICHARDS. *J. Biol. Chem.* 66, 275-80(1925).—An adaptation of the existing methods of estg. urea is described which makes possible the measurement of amts. of N in the form of NH_3 or urea of the order of 0.0005 mg., within a probable error of 10%. The essentials of the method consist in hydrolysis of the urea by heating with acid at 160°, the simultaneous nesslerization of the hydrolysis mixt. and a known $(\text{NH}_4)_2\text{SO}_4$ soln.

under identical conditions and quant. comparison of the intensities of color produced by a diln. method. The original must be consulted for the details. A. P. L.

Simple method of choline determination in blood. OTTO HIESCH. *Arch. ges. Physiol.* (Pflüger's) **209**, 779-80(1925).—A modification of the Reid Hunt method. G. H. S.

Composition of blood serum and its significance for the action of toxins. IV. **Method of determination of cholesterol in blood serum.** HANS HANDOVSKY AND KARL LOHMANN. *Arch. ges. The use of porcelain centrifugal tubes for chemical analysis (PINCUSSEN, ARINSTEIN) 1.

C—BACTERIOLOGY

A. K. BALLS

Laboratory pure culture apparatus. F. M. HILDEBRANDT. *Ind. Eng. Chem.* **17**, 1279(1925).—The app. offers a means of keeping a large vol. of nutrient medium contg. active organisms in such a way that the liquid may easily be withdrawn and can be replenished with fresh sterile nutrient. The app. can thus be maintained in continuous operation. It is suitable for acclimatizing organisms to various solns. and is also adaptable to anaerobic conditions. C. C. DAVIS

"Black yeasts" (*Zygonemata nigra* and a variable *Torula*). ERNST PRIBRAM. *Ergebnisse Physiol.* **24**, 95-106(1925) H. J. DEUEL, JR.

Significance of calcium for the genus *Citromyces*. S. J. KUSNETZOV. *Biochem. Z.* **157**, 339-49(1925).—The optimum p_H for the growth of *Citromyces* is 5.5. $(NH_4)_2SO_4$ serves best as a source of N. With $Ca(NO_3)_2$ in place of $(NH_4)_2SO_4$, the yields of citric acid are much lower on account of the toxicity of the Ca ion. Mg in place of Ca is less toxic and the yields of citric acid are higher. W. D. L.

The chemistry of the action of arsphenamine in vitro and in vivo. J. SCHUMACHER. *Biochem. Z.* **157**, 438-58(1925).—When yeast, under various conditions, is treated with arsphenamine, followed by treatment with Ag salts and alkali, the extent of combination of the arsphenamine with the components of the yeast cells is indicated by the intensity of coloration produced. Spirochetes bind arsphenamine base. The Ehrlich arsenoceptor is the lipoprotein of spirochetes and the action of the As is due to its depriving the cell of O. W. D. L.

Action of ter- and quinequevalent arsenic preparations. J. SCHUMACHER. *Biochem. Z.* **157**, 456-8(1925).—Tervalent As compds. are not acidic and are more sol in lipoids than the quinequevalent compds. Therefore, they are electively attached by the lipoproteins of spirochetes. W. D. L.

Effect of freezing and thawing on the bacteriophage. E. S. SANDERSON. *Science* **62**, 377(1925).—A bacteriophage active for *Staph. muscae* Glaser, and another, lytic for a human strain of *Bact. coli* were used. Heating at 60° for 45 min. inactivated the former, but only partially destroyed the latter. The lytic titers of the 2 were very const. One cc. quantities of the phages were frozen and rapidly thawed from 10 to 20 times (a CO_2 microtome being used to produce cold), yet their titers never varied from non-frozen portions used as controls. By contrast, samples of a 34-hr. old bouillon culture of *Bact. coli* lost 86 and 94% of its numbers after 10 and 15 freezings, resp. Apparently the bacteriophage is something other than a viable organism, unless it is an exception to the general rule that repeated freezing and thawing are injurious to living cells. L. W. RIGGS

The fixation of atmospheric nitrogen by yeast as a function of the hydrogen-ion concentration. E. I. FULMER AND L. M. CHRISTENSEN. *J. Phys. Chem.* **29**, 1415-8(1925).—The growth of yeast on synthetic media with atm. N as the sole source of that element has been found to be a function of the p_H . In order to obtain quant. results of the N fixation in these media an addn. of bios as growth stimulant was found advisable. In the present work cane molasses was used as the source of bios in an amt. of 6 g. per 100 cc. synthetic agar medium, and further 0.5 g. dipotassium phosphate acting as buffer. The yeast used came originally from a Fleischmann yeast cake. The p_H adjustment was made after sterilization in a special app. to obviate any changes that might take place during this operation. After inoculation the flasks were sealed with paraffin and furnished with a capillary vent for pressure equalization. Incubation took place at 30°. At specified intervals the flasks were examd. and analyzed. In a table given in the paper it will be seen that the medium, according to the method

of analysis used, lost N in the beginning and that the actual gain did not appear until after 6-8 weeks. It is also notable that the max. gain takes place at the same p_H in which there is a max. loss. The following hypothesis is advanced by the authors. Yeast is known to be rich in ring N compds. and in the early stage of growth these may be converted into compds. not determinable by the usual methods. Later in the growth a transformation into determinable N occurs. The fact that several investigators have failed to observe any N fixation under these conditions is probably due to this time element. The present data show conclusively that the fixation of N by yeast at 30° is a function of the p_H , there being 2 optimal concns., one at p_H 6.0 and the other at p_H 7.9, the latter being the more potent. D. THURSEN

Comparative studies of the action of the pneumococcus on bile acids and unsaturated fatty acids, found in bile in the form of soaps. ANTHONY KOZLOWSKI. *J. Exptl. Med.* **42**, 453-63(1925).—Ox bile contains the soaps of unsatd. higher fatty acids not only with 1 but also with 2 and more double bonds, in a diln. of about 1:600. These substances, when isolated from bile, exert an antiseptic action on the pneumococcus in a diln. of approx. 1:50,000 and kill the organism in a diln. of 1:5000 in approx. 1 hr. As their action is, then, about 100 times stronger than that of the conjugated bile acids, their presence in bile should be considered, whereas hitherto it has been entirely overlooked not only by bacteriologists but by physiologists as well. Since the soaps of unsatd. fatty acids do dissolve the pneumococcus cell in broth culture, Neufeld's conclusion is no longer valid. The method of isolation of the fatty acids is described. C. J. WEST

Soluble specific substance of a strain of Friedländer's bacillus. I. MICHAEL HEIDELBERGER, W. F. GOEBEL AND O. T. AVERY. *J. Exptl. Med.* **42**, 701-7(1925).—The E strain of Friedländer's bacillus yields, on fractionation, a N-free polysaccharide with sp. properties of the order possessed by the sol. sp. substances of the 3 fixed types of pneumococcus. It is a strong acid with an equiv. value of about 685, sparingly sol. in H₂O after drying, but yielding sol. alkali salts. The sp. optical rotation is 100°. The polysaccharide itself is nonreducing, but on hydrolysis with mineral acid yields reducing sugars among which glucose has been shown to be present. II. **Chemical and immunological relationships of pneumococcus Type II and of a strain of Friedländer's bacillus.** O. T. AVERY, M. HEIDELBERGER AND W. F. GOEBEL. *Ibid* 709-25.—The chem. and immunological properties of the sol. sp. substances of a strain of Friedländer's bacillus and pneumococcus type II are described and correlated and the serological and antigenic similarity of these biologically unrelated organisms is discussed as an example of heterogenetic specificity among bacteria. C. J. WEST

Soluble specific substance of pneumococcus. III. M. HEIDELBERGER, W. F. GOEBEL AND O. T. AVERY. *J. Exptl. Med.* **42**, 727-45(1925); cf. *C. A.* **18**, 3203.—The sol. sp. substance of Type II pneumococcus is apparently a weakly acidic, N-free polysaccharide made up chiefly of glucose units. Its acid equiv. is about 1250 and the sp. optical rotation is about 74°. It is not pptd. by Ba(OH)₂ or heavy metal salts with the exception of basic Pb(OAc)₂ and U compds. It reacts at a diln. of 1:5,000,000 with Type II antipneumococcus serum but does not ppt. Type I and Type III antisera at a concn. of 1:400. The substance is converted by Ac₂O and C₆H₅N into a very sparingly sol. tri-Ac deriv. The Type III sol. substance is also a N-free polysaccharide, has an acid equiv. of about 340 and is made up not only of glucose units but also those of either glucuronic acid or a deriv. Its sp. optical rotation is about -33°. It is pptd. by Ba(OH)₂ in excess and by heavy metal salts and is also rendered insol. by the addn. of concd. HCl. In as high a diln. as 1:6,000,000 it still reacts with Type III antipneumococcus serum. The Type I sol. sp. substance also appears to be a sugar deriv. but differs from the other 2 substances in its lower % of sugar liberated on hydrolysis and in contg. N as an apparent essential component. It is a strong acid and a weak base, is very sparingly sol. at its isoelec. point, which lies at about p_H 4 and rotates the plane of polarized light about 300° to the right. In spite of a N content of 5% the substance gives none of the usual protein color tests. One-half of the N is liberated on treatment with HNO₃ and reducing sugars appear at the same time, while the sp. reaction vanishes. Under the same conditions the Type II and III substances are unaffected by HNO₃. The substance gives the color reaction for glucuronic acid but yields mucic acid on oxidation, indicating a relationship of galactose. It appears that in this substance a N sugar deriv. is linked to galacturonic acid through the reducing group of the latter. The Type I substance is pptd. by Ba(OH)₂ in excess, by heavy metal salts and by phosphotungstic acid. In the sp. precipitin reaction with homologous Type I antipneumococcus serum it can be detected in dilns. as great as 1:6,000,000 while at a concn. of 1:400 it gives a faint cloud with Type III antiserum.

These substances differ from the starch-glycogen group of carbohydrates in giving no color with I and in their resistance to the ordinary carbohydrate-splitting enzymes.

Physical and chemical factors in the growth of asparagus. E. B. WORKING. Univ. Arizona Agr. Expt. Sta., *Tech. Bull.* 5, 124 pp., 14 figs(1925).—The 3 external factors of greatest importance in the growth rate of the young shoots are the temp., moisture content and the salt balance of the soil. Increase of growth rate was always found with increasing temps. up to the highest which occurred during the expts.; but temp. cannot be considered a limiting factor, as an improvement in the salt balance of the soil induces more rapid growth at the same temps. The addn. of Na salts in medium or low concn. improved the salt balance of the soils and nutrient solns. used. The amino acids present in the young stalk are favorable to high imbibitional swelling of a protoplasm contg. a high % of pentosan. A bibliography is appended. P. R. D.

Experiments with "finger and toe" disease of swedes. T. WHITEHEAD. *Welsh J. Agr.* 1, 176-84(1925).—The av. compn. of 4 varieties of swede roots was as follows:

Variety	Dry matter	Total sugar in roots	Sugar in juice	
			Reducing sugar	Cane sugar
Magnum Bonum	8.8	5.47	5.35	0.31
Danish, 25	10.6	5.86	5.80	0.29
Danish, 4	11.1	6.25	6.20	0.29
Yellow turnip	8.5	3.32	3.30	0.15

Some nitrogenous constituents of the juice of the alfalfa plant. VI. **Asparagine and amino acids in alfalfa.** H. B. VICKERY. *J. Biol. Chem.* 65, 657-64(1925); cf. *C. A.* 18, 3407; 19, 3514.—Asparagine, aspartic acid, tyrosine, phenylalanine, serine, leucine, valine and alanine have been isolated from alfalfa juice. The aspartic acid obtained after hydrolysis probably represents asparagine. At least 55% of the amino N of the amino-acid fraction is accounted for as asparagine and the aspartic acid found after hydrolysis indicates that more of this substance is present. Although no other amide has yet been found, it is probable that other substances yielding NH_3 on mild acid hydrolysis are present in alfalfa juice. Serine and alanine have not been previously reported as occurring in plant juices; they were definitely identified as α -naphthyl-hydantoic acid derivs.

A. P. LOTHROP

Carbo- and nitrogen transformations in the decomposition of cellulose by filamentous fungi. H. HEUKLEKIAN AND S. A. WAKSMAN. *J. Biol. Chem.* 66, 323-42 (1925).—"The C and N transformations in the decompn. of cellulose by 2 typical soil fungi, a *Trichoderma* and a *Penicillium*, have been studied. It has been found that cellulose (in the form of filter paper) is completely decompd. by these organisms, giving CO_2 as the only waste product. No intermediary products are left in the medium. A considerable part of the C is reassimilated by these organisms and built into protoplasm. These results have been obtained both in a direct and an indirect way. It has been conclusively shown that the C evolved as CO_2 and the C assimilated by the fungi account for nearly all of the C of the cellulose decompd. The divergencies are small and are due to exptl. error. The C and N assimilated show a definite relationship to one another. The organisms prefer NH_3 to nitrate as a source of N. This is assimilated and transformed into microbial protoplasm. A direct correlation is thus found between the amt. of cellulose decompd. and the amt. of N transformed into an insol. org. form. In the decompn. of cellulose the only residual substance is thus found to be the fungus protoplasm. Of course the synthesized fungus mycelium will be further decompd. in normal soils by other microorganisms, resulting in the liberation of N in an available form."

A. P. LOTHROP

The nitrogen constituents of celery plants in health and disease. G. H. COONS AND L. J. KLOTZ. *J. Agr. Research* 31, 287-300(1925).—Celery leaves affected with *Cercospora apii* and *Septoria apii* have a lower percentage of total N in the diseased

than in the healthy tissue. Nitrites are present in the diseased material. A comparison of the nitrogenous compds. present showed in percent of total N more NH_4 , humin and protein in the diseased than in the healthy tissue and less acid amide, non-protein, basic and hydrolyzable N. The results are thought to be best explained as due to the decompn. of the host by the parasite in a simple food relation. W. H. R.

Copper in the legumes. I. HIRANO AND R. MIKUMO. *J. Pharm. Soc. Japan* No. 525, 992-4 (1925).—The Cu content of various legumes and its distribution between seed coat and embryo were estd. by a colorimetric method after the sample is ashed and the Cu is converted to the NH_4 Cu complex. The results are given in mg. of Cu in 1 kg. of dried samples as follows: soy beans 15.896; *Phaseolus mungo* L. (var. *subtilibata*, Ir and Sav.) 5.855; green peas 2.687, red peas 5.291; *Vicia faba* L. 8.024; black beans 12.156, *Phaseolus vulgaris* L. 6.183, "toramame" 6.183; peanut 6.778; and "sodefuri mame" 2.051. The seed coats contain 30-40% of the total Cu in legumes. S. T.

Efficiency of photosynthesis of *Chlorella* (ADAMS) 10.

PHILIP B. HAWK

Avitaminosis, receptivity to infection, and virulence of microorganisms. G. PETRAGNANI. *Rend. adunanze dell' accad. med.-fis. fiorentina; Sperimentale* 79, 951-7 (1925).—Attenuated anthrax cultures do not increase in virulence when injected into pigeons in avitaminosis or when grown in their blood. The lowered resistance to bacterial invaders of animals in avitaminosis is attributed to a depressed cellular functioning. Setti's conclusions (*C. A.* 17, 819), opposed to these, are criticized. M. H.

The behavior of fat in the blood of children during a prolonged fast. L. SPOLVERINI AND A. VANELLI. *Pediatrics (Riv.)* 33, 1253-63 (1925).—The serum of normal children from 6 months to 2 years old was observed in the dark field and the fat droplets were counted, the children being kept first on a normal diet and then for 50-60 hrs. on sweetened barley coffee. A period of fat-free diet was in some cases interposed between normal diet and fast. Unlike the sugar content the fat content of the blood shows considerable variations, mainly in connection with the ingestion of food. During the first 24-36 hrs. (nurslings) and 48-55 hrs. (weaned children) the fat content suffered a sudden drop and finally disappeared completely. A noticeable, often marked lipemia followed, which unlike digestive lipemia was characterized by the prevalence of large and medium sized fat droplets and was apparently due to the mobilization of depot fat. The fasting lipemia appeared in nurslings much sooner than in weaned children and was more pronounced and const. The tolerance of all children to the fast was a very good one. MARY JACOBSEN

Nitrogen metabolism in nutritional disturbances. IVO NASSO. *Pediatrics (Riv.)* 33, 1264-78 (1925).—Nurslings fed on evapd. milk were studied. In normal infants the relative values of excreted N hardly differed from those of breast-fed children. Apparently the latter retain less N, since the N content of evapd. milk is higher than that of cow or woman's milk. The somewhat higher NH_3 and lower urea N as compared with that of the adult may indicate that the infantile organism tends to neutralize its acids with NH_3 . Acute dyspepsia showed only a slight deviation from normal. In chronic disturbances there was in one case a considerably reduced retention of N, increased excretion in the feces and normal rates in the urine, while another case presented N deficit and increased excretion of N in the feces and of NH_3 in the urine. MARY JACOBSEN

Alimentary and adrenaline glucemia in the new born. LUIGI AURICCHIO. *Pediatrics (Riv.)* 33, 1274-8 (1925).—The blood of the new born contains glucose previous to any food ingestion, the content being about the same as that in the adult. Ingestion of glucose caused an increase of 50-100%, first noticeable after 15 min. The max. is reached in 30 min.; the decrease begins after 1 hr. with the return to normal after 2 hrs. An adrenaline injection doubled the sugar content in 15 min. The decrease began only after 2 hrs. MARY JACOBSEN

Vitamins. V. Storage of vitamin A by young white rats after feeding horse-flesh to the mother during pregnancy and afterwards. A. SCHEUNERT AND A. J. CANDELIN. *Biochem. Z.* 159, 83-8 (1925); cf. *C. A.* 19, 2841.—The litters of rats which have not been deprived of vitamin A have stored enough of this vitamin to produce normal growth for about 30 days after weaning. Vitamin A is present in lean horse meat. W. D. L.

Changes in the intestinal flora of rats on a calcium-deficient diet. R. E. HOFF-

STADT AND S. J. JOHNSON. *Am. J. Hyg.* **5**, 709-23(1925).—A diet in which low Ca was the limiting factor, but derived chiefly from natural foodstuffs (white flour, oat meal, lean beef, beans, potatoes and apples) and the same diet to which 1.5% CaCO_3 was added, were fed to white rats and the intestinal picture was studied. On the low Ca diet, constipation was observed as evidenced by dryness and change of color of feces and painful defecation. There was also noted a low aerobic bacterial count, but no relation was evident between types of organisms, aerobic and anerobic, present and the clinical condition of the animals. On autopsy the small intestine showed loss of elasticity and thinness of the wall, which was considered to be the chief contributing factor in the intestinal stasis.

H. B. LEWIS

The chemistry of proteins and its relation to nutrition. D. B. JONES. *Am. J. Pub. Health* **15**, 953-7(1925).—Review concerned particularly with the question of the essential amino acids.

H. B. LEWIS

Vitamins in canned foods. IV. Green peas. W. H. EDDY, E. F. KOHMAN AND V. CARLSSON. *Ind. Eng. Chem.* **18**, 85-9(1926).—Fresh green peas are relatively rich in vitamins A, B and C, but no evidence was obtained of the presence of the anti-rachitic vitamin. Small peas contain more A and C, and less B than large peas. Cooking or canning did not affect the A or B content, and canning is less destructive to C than kettle cooking, probably because of exclusion of O in canning. Blanching is relatively more destructive than processing. Reheating canned peas in an open kettle after removal from the can does not materially affect the content of C. Canned peas have at least half the value of butter as sources of A, are richer than milk, tomatoes or oranges in B, and nearly as rich as oranges or tomatoes in C. The protective dose of canned peas for guinea pigs is as 3-5 g. compared with 1.5-3 g. of orange juice, and 2.5-3 g. of tomato. For the detn. of comparative values the methods of Sherman were used.

H. B. LEWIS

Technic for studying vitamin B. A. H. SMITH, G. R. COWGILL AND HILDA M. CROLL. *J. Biol. Chem.* **66**, 15-21(1925).—When exptl. animals used in studying vitamin B are prevented from eating their feces definitely increased daily dosage of the vitamin-bearing material is required for normal growth. The rate of decline after withdrawing the source of vitamin B is more rapid when animals are confined in false-bottom cages and more speedy failure of very young rats on vitamin B-free diets occurs under these conditions. The animal-feeding method of testing for vitamin B can only give accurate *absolute* results for a given product when the exptl. animal is prevented from conserving his supply of this food factor by coprophagy. Frequent thorough cleaning of the cages is also necessary and more clear-cut exptl. results are obtained if each animal is caged separately. The animal-feeding method in the old style cage possesses value if only *comparative* results not highly quant. in character are desired. These observations confirm those of Steenbock, Sell and Nelson (*C. A.* **17**, 2305) and are not in accord with those of McCollum, Simmonds and Becker (*C. A.* **19**, 2066).

A. P. LOTHROP

The determination of cystine by means of feeding experiments. H. C. SHERMAN AND ELLA WOODS. *J. Biol. Chem.* **66**, 29-36(1925).—The basal diet in which the growth-limiting factor is cystine was as follows: whole milk powder 16.7, cod-liver oil 1.0, dried brewers' yeast 1.65, salt mixt. 1.65, starch 79%. "When carefully standardized young rats are fed this basal diet, with and without graded addns. of cystine, it is possible to det. a direct linear or arithmetical relationship between the added cystine fed and the added growth thereby induced, up to an added gain of at least 10 g. in an exptl. period of 6 weeks, induced by the addn. of 0.025% of cystine to the basal diet, and probably up to 0.04% added cystine with an added gain of 17 g. Parallel expts. with graded addns. of casein to the same basal diet gave correspondingly graded responses in the growth rate.* Within the range of growth increase in which the response to added cystine was in arithmetical proportion to its amt., it is believed that the response to the added casein may be interpreted as a measure of the cystine (or cystine plus nutritionally equiv. S-contg. radicals) furnished by the casein. Thus interpreted, the results would indicate that casein contains not less than 1.3% nor more than 2.5% of cystine, or that approx. $\frac{3}{8}$ to $\frac{1}{4}$ of the total S in casein is in the form of cystine or of cystine plus other S-contg. radicals which are interchangeable with cystine in nutrition. The lower limit of the range of the possible % of cystine in casein thus indicated by these feeding expts. is higher than the proportion of cystine obtained from casein *in vitro* by present analytical methods. With the development of a suitable basal diet for each, it should be possible to apply the same general principle to the quant. detn. of other nutritionally essential amino acids." A. P. LOTHROP

Soft pork studies. I. Formation of fat in the pig on a ration moderately low in fat.

N. R. ELLIS AND O. G. HANKINS. *J. Biol. Chem.* **66**, 101-22(1925).—"The progressive hardening of hogs on a ration contg. a moderately low amt. of softening fat such as is found in corn is accounted for as follows: The change from a soft fat as found in young, immature hogs to a hard fat in older, mature hogs was accompanied by an increased rate of fat deposition. This increased rate of fat deposition caused a widening of the ratio of body fat derived from carbohydrate and protein (hard) to that derived from ingested fat (soft). The change in the compn. of the body fat resulted in a decrease in the I no. and n and an increase in the m. p. The effects on the proportions of the fatty acids were an increase in the % of total satd. acids and a decrease in the % of linolic acid with the % of oleic acid remaining nearly const." A. P. LOTHROP

The antirachitic value of irradiated cholesterol and phytosterol. IV. Factors influencing its biological activity. A. F. HESS, MILDRED WEINSTOCK AND ELIZABETH SHERMAN. *J. Biol. Chem.* **66**, 145-60(1925); cf. *C. A.* **19**, 2068, 2972-3.—"Irradiated vegetable oil maintains its acquired antirachitic potency for at least a year and dried milk for at least 3 months. Activated cholesterol loses its potency much more readily; most rapidly when kept in the dry state, less quickly when kept in H_2O and slowly when stored in oil. Prolonged intense irradiation destroys the antirachitic properties of activated cholesterol which cannot be regained by subsequent exposure to ultra-violet light. The process is not reversible. Cholesterol can be activated in an atm. of N_2 . It does not lose its potency when subjected to a partial vacuum. Furthermore no difference was found, by means of combustion, between the O content of the non-irradiated cholesterol and that irradiated 1 hr. Recrystn. of irradiated cholesterol brings about a loss of its activity, the successive fractions possessing diminishing antirachitic value. Irradiation of these deactivated fractions brought about incomplete activation in 3 fractions and no activation in the 4th. Activated cholesterol does not suffer a loss of potency by prolonged contact with Me_2CO , $CHCl_3$, or C_6H_6 . The cholesterol extd. from egg yolk or from bone marrow has no antirachitic value."

A. P. LOTHROP

Studies on the mineral requirement of swine: The effect of common salt and charcoal, sodium sulfate and calcium phosphate on the growth of pigs. P. L. CAVILLERO. *Philippine Agr.* **14**, 373-8(1925).—"Four groups of 4 pigs each were fed the same basic ration. Lot 1 was the control and received no mineral matter except that naturally occurring in the feed. The other lots all received NaCl and charcoal and in addn. lot 3 received Na_2SO_4 and lot 4 $Ca_3(PO_4)_2$. There was no material difference in the amt. of food consumed or gain in wt. made by lots 1, 2 and 3. The animals fed $Ca_3(PO_4)_2$ made an av. gain in wt. 34% greater than that of any other group. The controls laid on more fat in proportion than the others. The latter and especially lot 4, had larger and longer bones, better appetites, longer and coarser hair, were more active and less infected with parasites."

A. L. MEHRING

Physical and chemical properties of biosterin (a name given to fat-sol. A) and its physiological significance. K. TAKAHASHI, Z. NAKAMIYA, K. KAWAKAMI AND T. KITASATO. *Sci. Papers Inst. Phys. Chem. Research* **3**, 81-148(1925).—"Cod-liver oil which was potent in vitamin A was treated as previously described (cf. *C. A.* **17**, 1984) and crude biosterin was obtained. This was purified by extn. with petrole ether and MeOH and the product was called refined biosterin (II). It had the compn. C 81.07, H 11.14, sp. gr. 0.9572, n_D^{20} 1.5676. Further attempts to purify (II) by its different solubilities in solvents failed, whereupon it was crystd. from its soln. in acetone by cooling below -60° by means of a mixt. of CO_2 and H_2O . The product (III) had nearly the same properties and consts. as (II). The refined product (II) was then distd. in a special flask in an oil bath, about one half of the sample going over at $147-150^\circ$ under a pressure of 0.02 to 0.03 mm. and at a temp. of about 180° of the bath. The portion which distd. below 190° was fractionally distd. when 30 to 40% of the original sample was obtained at $147-150^\circ$. This substance gave consts. similar to those of (II) and had the growth-producing properties of vitamin A, showing that vitamin A can be distd. A substance similar to biosterin in its chem., phys. and physiol. properties was obtained from spinach. Biosterin resembles the carotinoids. It affects a dry photographic plate to a much greater degree than do the drying oils or terpenes. The reason for this activity is obscure. Biosterin dissolves in the usual org. solvents and in the fatty oils but is insol. in water. Its soly. in 90% MeOH or EtOH or petrole ether distinguishes it from carotin and xanthophyll. It is readily adsorbed from its solns. by fuller's earth or animal charcoal. Its empirical formula is given as $C_{27}H_{44}O_2$. Biosterin gives several color reactions, the most important of which is an indigo blue color when to its $CHCl_3$ soln. concd. H_2SO_4 is added. This color soon changes to a dark brown. Biosterin which has lost its vitamin efficacy gives a red color with H_2SO_4 . I absorption and Br

addn. products show its unsatd. character. Biosterin can be hydrogenated by the use of Pt black as the catalyst. When kept in air in a desiccator for a long time it gained O, gave a red color with H_2SO_4 and lost its efficacy upon the animal. It forms an acetate and benzoate, also a digitonide with digitonin. Much work was reported on the effects of feeding normal and supernormal doses of biosterin to dogs and other animals.

L. W. RIGGS

Relation of the hypophysis to carbohydrate metabolism. TUMIO FUKUI. *Arch. ges. Physiol.* (Pflüger's) **210**, 427-31(1925).—The injection of hypophysis preps. exerted no noteworthy effect upon the carbohydrate content of the liver of rats on a normal diet. Hypophysis ext. given simultaneously with thyroid preps. did not modify the characteristic loss of the liver carbohydrates due to the latter. G. H. S.

Antirachitic effect of the "unsaponifiable portion" of cod-liver oil. H. BEHRENDT. *Z. Kinderheilk.* **39**, 619-27(1925).—The unsaponifiable portion of cod-liver oil administered to 12 rachitic children caused improvement in 11, as detd. by clin. conditions, röntgenological examn. and blood chem. tests. G. H. S.

Percentage distribution of the caloric values of foodstuffs as to protein, fat and carbohydrates. CLEMENS PIQUET and RICHARD WAGNER. *Z. Kinderheilk.* **40**, 26-45 (1925).—Tabulated data on 542 substances. G. H. S.

Vitamin C content of cow milk and the effect of different pasteurization procedures. W. BLUMENBERG. *Z. Kinderheilk.* **40**, 177-96(1925).—The amt. of C vitamin is small. Pasteurization reduces, sterilization destroys, the antiscorbutic property. Heating for 30 min. at 63° is more destructive than heating at 85° for 15 min. G. H. S.

Significance of cow milk whey in the origin of acute diarrheal nutritional disturbances in infants. IV. Whey and lactase. HEINRICH DAVIDSOHN. *Z. Kinderheilk.* **40**, 251-8(1925); cf. *C. A.* **19**, 1446. —Compared with a lactose-water soln., whey retards sugar splitting. Dilm. of the whey content to $\frac{1}{3}$ converts the inhibition into a favoring action. Protein-free whey markedly favors the splitting as compared to protein-contg. whey, and somewhat as compared to a lactose soln. Dilm. of the protein-free whey to $\frac{1}{3}$ causes no material change in the velocity of the reaction. A lactose-water soln. contg. whey albumin shows a much slower lactose splitting than does a lactose-water soln. alone and it is somewhat slower than in whole whey. Thus, the lactose splitting is inhibited by the presence of whey salts, *i. e.*, the non-colloidal constituents of the whey. After dilm. to $\frac{1}{3}$ the effect of the latter outweighs the retarding effect of the albumins. Casein (lactana) in low concns. (0.5-1%) favors, in higher concns. (3%) is of questionable advantage to the process. Protein-free whey + lactana favors the reaction much more than a lactose soln. with the same amt. of lactana. The clinically observed fact that protein-free whey and casein are more harmful to the conduct of intestinal activity than lactose-water and casein is not explained by the above facts.

V. Whey and blood sugar. KLAUS KEILMANN. *Ibid* 259-67.—Study of the blood sugar curves after the administration of lactana and lactose in (a) whey, (b) protein-free whey, and (c) water showed that with (a) there occurred a significant retardation of the hyperglucemia, which was not to be referred to the period of stay in the stomach or to the course of the lactose splitting, but to a dominating inhibition of the absorptive activity of the intestinal mucosa. This inhibition proceeds from the whey proteins, in conjunction with the protein-free whey residue. In itself the whey protein is entirely without influence, but when with protein-free whey, after a prompt rise in the blood-sugar curve similar to that occurring with sugar-water, there is a slow and irregular return to the initial value. Since this action vanishes after dialysis of the protein-free whey, it is obviously associated with dialyzable substances.

VI. Sugar absorption with human milk, with undiluted and diluted cow milk, and with protein milk. KLAUS KEILMANN and FLORA ROSENBUHD. *Ibid* 268-71.—Sugar absorption occurs quickly and its curve falls abruptly with human milk, resembling that characteristic of aq. sugar solns. With whole milk there is a delay in sugar absorption, resembling that noted with whey. Dilm. of the milk to $\frac{1}{3}$ removes this delay. With protein milk, or with a whey content of but 50%, the sugar absorption was more rapid than with whole whey, but slower than with human milk, sugar-water solns., or with greater dilns. Apparently absorption is delayed in severe dystrophies and dyspeptic conditions. The conformity of the blood sugar curves with human milk and aq. sugar solns., as compared with that with cow milk, would not imply any sp. stimulation of the absorptive process by the natural food, but indicates rather that in the cow milk the whey is inhibitory.

VII. Whey and retention in the stomach. W. BLOCK and F. KOENIGSBERGER. *Ibid* 272-4.—With water the retention in the stomach is some 27 to 48% shorter than with whey.

VIII. Whey and lactosuria. ERNST BERNHARD. *Ibid* 275-6.—Whey renders

the intestinal mucosa permeable for lactose. **IX. Conclusion.** H. FINKELSTEIN. *Ibid* 277-80.—A summary of the above series of papers. G. H. S.

Effect of feeding cod-liver oil to cows as regards the vitamin content of the milk. RICHARD WAGNER AND HANS WIMBERGER. *Z. Kinderheilk.* **40**, 295-308(1925).—The milk of cows, which were fed large doses of cod-liver oil for 7 months, had no detectable curative effect on rickets in infants. The content in vitamin A, as well as the anti-rachitic value of the milk, as detd. by tests in rats, was higher than normal to but an insignificant extent. G. H. S.

ANDREW HUNTER

Action of splenic extracts on the movements of the digestive tract. C. MAZZANTI. *Sperimentale* **79**, 741-62(1925).—Fresh exts. which have not autolyzed or been exposed to acids or bases show a hypertonic action on the smooth musculature of the intestine only in high concns., indicating the absence of a peristaltic hormone in the secretion. M. HEIDELBERGER

Fat content of the lungs of new-born infants. C. COCCHI. *Rend. adunanza dell'accad. med-fis. fiorentina; Sperimentale* **79**, 961-6(1925).—The amt. found diminishes rapidly after the initiation of the respiratory function, and is also less in premature infants. A table is given. Averages are: for full-term infants who have not respired fatty acids 9.7%, cholesterol and unsaponifiable matter 1.7%; for full term infants who have respired 4.6 and 1.4%, resp. Analyses were also made in the case of new-born rabbits, the values varying in the same sense. The theory is thus supported that the fat of high caloric value is used for purposes of energy in the lung itself where it is needed before food is ingested. M. HEIDELBERGER

Sedimentation and Rouleaux formation. I. ERIC PONDER. *Quart. J. Exptl. Physiol.* **15**, 235-52(1925).—Human red cells lose their discoid form and become spherical (Gauchian change) in isotonic NaCl soln., Ringer's soln., Fleisch's soln., Brinkmann's fluid and isotonic citrate soln. These changes are probably due to variations in surface tension. The cells return to the discoid form on the addn. of a small quantity of serum. NH_4 oxalate prevents the formation of the spherical form. The equation for the sedimentation rate of the spherical form is given. The velocity is const. during the first 24 hrs.; with increase in time the rate decreases. Similar results were obtained with cells of the ellipsical form (birds, reptiles, amphibia and fishes). Sedimentation varies directly with the temp. Concn. does not affect sedimentation to any appreciable extent. Length and diam. of tube (except in casts of very narrow tubes) do not influence the sedimentation of cells in saline. FRANCES KRASNOW

Note on the appearance of mammalian erythrocytes under dark ground illumination. W. G. MILLAR. *Quart. J. Exptl. Physiol.* **15**, 253-7(1925).—No sign of internal structure can be seen in the human cells. There are 2 forms of crenation. Cells, after the Gauchian change, show an irregular granularity of the surface. Cells immediately before hemolysis assume a spherical form. The remains of the cells hemolyzed by saponin show the wrinkled appearance of collapsed bladders. FRANCES KRASNOW

Some technical points important for the study of the metabolism of rabbits. V. KORENCHESKII. *Quart. J. Exptl. Physiol.* **15**, 259-61(1925).—Discussion. F. K.

The pancreas of teleostean fishes and the source of insulin. SWALE VINCENT, E. C. DODDS AND F. DICKENS. *Quart. J. Exptl. Physiol.* **15**, 313-7(1925).—The authors show "that pancreatic tissue derived from teleostean fishes contains a certain amt. of islet tissue and it therefore seems that the source of insulin remains undecided. A yield corresponding to that obtained from mammalian pancreas was extd. from zymogenous tissue of a teleostean pancreas, even though the material collected under this head inevitably contained a great deal that was not pancreas at all." F. K.

The active principles of the posterior lobe of the pituitary body. WALTER SCHLAPP. *Quart. J. Exptl. Physiol.* **15**, 327-47(1925).—"When the depressor-free exts. of the posterior lobe of the pituitary body are boiled with dil. HCl, the oxytocic, pressor and melanophore responses evoked by them are destroyed slowly and simultaneously. By treating depressor-free exts. with *N*-butyl alc. it is possible to sep. a fraction into which the greater part of the oxytocic activity has passed." During treatment with H-S in suitable concns. of Pb acetate, all the active pressor and melanophore substances are adsorbed on the PbS ppts. to a much greater extent than the oxytocic principle. The expts provide no positive proof that the pressor and melanophore responses are due to distinct substances. FRANCES KRASNOW

Distribution of iodine in the decomposition products of the thyroid gland. N.

ABELLES AND H. POPPER. *Biochem. Z.* **159**, 126-9(1925).—A thyroid prepn. (I = 0.25%) is hydrolyzed with 10% H_2SO_4 . Of the I present, 33% is in the acid-insol. residue and it all may be extd. by EtOH . If hydrolysis occurs in the presence of HCHO only 4.4% of the I in the acid-insol. residue is extd. by EtOH . When HCl is used in place of H_2SO_4 , 13.6% of the I remains undissolved, and in presence of HCHO , 21.4%. Hydrolysis with NaOH leaves from 28.5 to 18.8% of the I undissolved. W. D. L.

Carbohydrate utilization. I. Rate of disappearance of *d*-glucose from the blood. VINCENT DU VIGNEAUD AND W. G. KARR. *J. Biol. Chem.* **66**, 281-300(1925).—Fasting invariably decreases the rate of glucose disappearance from the blood in a normal rabbit following a hyperglucemia from glucose ingestion, the longer the fast the greater the reduction in the rate of disappearance. Similar results are obtained when the glucose is injected intravenously. This fact offers very definite evidence that in the decreased tolerance due to fasting the rate of disappearance from the blood is involved and not the absorption of glucose from the intestine. The rate of the reduction of the hyperglucemia after fasting is markedly influenced by the sp. foodstuffs; feeding protein with or 4 hrs. before the glucose test meal has little or no influence on the blood sugar curve but greatly increases the rate if given 18 hrs. previously; fat fed 18 hrs. before the glucose ingestion decreases the rate while glucose itself slightly increases it. Adrenaline given 18 hrs. previous to the test meal increases the rate while morphine does not, although both produce hyperglucemia; this indicates that a previous hyperglucemia is not the only stimulating factor. A decreased rate is observed on giving a test meal immediately after an insulin hypoglucemia has returned to normal. NaHCO_3 administered during a fast prevents the decrease in the rate of disappearance of blood sugar but detns. of the blood p_{H} and CO_2 capacity indicates that acidosis is not the predominant factor in causing this change during a fast. The exptl. data emphasize greatly the importance of carefully controlling the diet, period of fasting and medication before performing the customary sugar tolerance test used in clinical diagnosis.

A. P. LOTHROP

The influence of pregnancy upon the lipoids of the blood. MARGARET TYLER AND F. P. UNDERHILL. *J. Biol. Chem.* **66**, 1-13(1925). The total Et_2O ext. of whole blood in pregnant women is higher than the non pregnant values as early as the 3rd month and there is an increase from then till term; the av. value at term in 11 cases was roughly 50% higher than the non-pregnant values and 30% higher than the value at 3 months. Cholesterol, cholesterol esters and lecithin increase gradually, each being roughly $\frac{1}{3}$ higher at term than at 3 months. The relation of cholesterol esters to total cholesterol remains fairly const. but the esters form a larger proportion than in non-pregnant women. The relation of lecithin to cholesterol remains fairly const. and is within normal limits continuously. During the first 2 weeks of the puerperium the values for the Et_2O ext. and for the individual lipoids of whole blood remain high. A. P. L.

The effect of changes in the circulation on carbohydrate utilization. F. A. CAJORI, C. Y. CROUTER AND RALPH PEMBERTON. *J. Biol. Chem.* **66**, 89-100(1925).—An exaggerated and prolonged hyperglucemia can be induced in many subjects by interfering with the blood supply to large muscle masses through elevation of the legs and one arm. The rate at which sugar is removed from the blood can, therefore, be changed by a procedure which is purely mech.; the chem. processes do not seem to be involved and elevation of the legs for 45-50 min. has no effect on the fasting blood sugar level. Purely mech. factors (the condition of blood supply and blood flow in the tissues) should be taken into consideration in interpreting the nature of a low sugar tolerance test.

A. P. LOTHROP

The properties and composition of oocytin. II. G. W. CLARK AND P. W. SHARP. *J. Biol. Chem.* **66**, 123-31(1925); cf. *C. A.* **12**, 1970.—"Oocytin is present in the blood of the following mammals: beef (bull, ox, cow and calf), sheep (lamb, wether), pig, dog, horse, chicken and turkey (gobbler and hen). It therefore seems probable that oocytin is present in the blood of all mammals. Long standing of serum (approx. 15 months) at low temp. (4°) has no appreciable effect upon the yield of oocytin or upon the potency of the substance in forming fertilization membranes. Both the age and sex of the animal may influence the yield and membrane-forming properties of the oocytin obtained; that prepd. from old animals is more potent than that from young animals of the same species and larger yields are obtained from female blood. Oocytin is probably not present in appreciable amts. in the body transudates. Membrane formation can be induced by thymus, salmon sperm and yeast nucleic acids but these substances are much less effective in this respect than oocytin. From work with fowl blood it seems probable that the source of oocytin is nuclear material derived from the red cells rather than from the leucocytes as suggested by Robertson."

A. P. LOTHROP

Further studies on the parathyroid hormone. II. J. B. COLLIP AND E. P. CLARK. *J. Biol. Chem.* **66**, 133-7(1925); cf. *C. A.* **19**, 2076, 2520, 3523.—A detailed method for the purification of the parathyroid hormone is described; extrn. is made with hot 5% HCl followed by salting out of the active substance with NaCl and several isoelec. pptns. The material behaves as a fairly well-characterized substance of protein nature with properties similar in many ways to those of insulin. It contains 15.5% of N and also some S and Fe but no P. It has a sharp isoelec. point at p_H 4.8. It is pptd. from acid soln. by half satn. with $(NH_4)_2SO_4$ and gives the common protein tests. Its physiol. activity is destroyed by boiling for 1 hr. with either 10% HCl or 5% NaOH and by the action of pepsin and trypsin. It does not dialyze through collodion membranes and is removed from soln. by Norit and H_2WO_4 . No change in properties could be detected after 10 repptns. The purified substance is sol. to the extent of 0.1% in abs. alc. A. P. LOTHROP

The influence of *l*-hydroxystearic acid on acidosis. R. WEST AND ETHEL M. BENEDICT. *J. Biol. Chem.* **66**, 139-44(1925).—The investigation was undertaken to det. whether or not an even C fatty acid with a negative group attached to one of the even C atoms (α , γ , ϵ , etc.) would yield acetone in the body. *l*-Hydroxystearic acid ethyl ester, m. 44° , was chosen as it can be readily homogenized to a cream with skimmed milk and is from 75 to 85% absorbed. When fed to normal subjects in ketosis a reduction of the ketosis resulted in all cases. No significant change in the N excretion occurred. While the excretion of acetone bodies became less, the total org. acids fell but little or not at all, suggesting that the material fed was probably being oxidized to some other acid than acetoacetic and its derivs. A. P. LOTHROP

The concentration of chlorides in the glomerular urine of frogs. J. T. WEARN AND A. N. RICHARDS. *J. Biol. Chem.* **66**, 247-73(1925).—The nephelometric method of Richards for the estn. of minute quantities of Cl has been adapted for the detn. of the Cl concn. of glomerular urine, the modification permitting its detection in concns. lower than 1×10^{-7} . "Comparison of the Cl concns. of glomerular and bladder urines simultaneously eliminated by frogs in 13 expts. under various conditions confirms the qual. evidence previously advanced in proof of glomerular elimination and tubular reabsorption of Cl. The figures show that Cl is absorbed at a faster rate than H_2O , even when plasma Cl is more than double its normal value as a result of injection of NaCl. In 10 of 13 expts. the plasma Cl concn. was also detd. In all but one of these, glomerular Cl was higher than plasma Cl. In 7, the difference amounted to more than 15% of the latter; in 4, more than 28%. Conceding the possibility of errors of technic amounting to 10%, we are forced to conclude that the filtration theory, as at present defined, is not adequate to explain our results. If subsequent work shall confirm these, it is clear that the processes concerned in glomerular filtration require further study." A. P. LOTHROP

Physiological ontogeny. A. Chicken embryos. II. Catabolism. Chemical changes in fertile eggs during incubation. Selection of standard methods. H. A. MURRAY JR. *J. Gen. Physiol.* **9**, 1-37(1925).—Loss of H_2O from the hen egg during incubation is a function of the humidity of the atm. surrounding the egg. The factors influencing the humidity are: circulation of the air, atm. temp., thickness and area of egg shell and conditions within the egg, the most important of which probably is the amt. of heat produced by the embryo. The latter factor assumes importance only after the 3rd. or 4th. day of incubation. A formula is given for calcg. the surface area of the egg. The egg shell loses wt. during incubation; near the end of the embryonic cycle this loss seems to parallel the wt. of the embryo. A loss of solid matter occurs during incubation, about 98% of the material oxidized being fat. On the basis of chem. analysis, the CO_2 produced is assumed to be derived from the oxidation of fat. The total solids fats and protein in the whole egg during incubation have been calcd. from the exptl. data. III. **Weight and growth rate as functions of age.** *Ibid* 39-48.—The av. wt. of chicken embryos between 5 and 19 days old may be expressed by the formula: $W = Kt^{2.6}$, where $K = 0.668$. The velocity of growth (% increase in mass) is inversely proportional to embryonal age. The product of velocity and time is a const. (3.6). The negative acceleration of growth also decreases with age. C. H. R.

The fixity of basal metabolism. F. G. BENEDICT AND ELIZABETH E. CROFTS. *Proc. Nat. Acad. Sci.* **11**, 585-8(1925).—"The expression 'basal metabolism' is used to denote the energy production of man during complete muscular repose and 12 hrs. after the last meal." One man and 7 women (college students) served as subjects. The basal metabolism was measured, first, after the subject had rested quietly in bed during the night, well covered. The subject then rose, went through the regular routine of bathing and dressing, walked 10 min. in the open air, returned to the lab.,

climbed 3 flights of stairs and while still clothed lay on a bed 30 min, covered with a light blanket, when the basal metabolism was again measured. These measurements were repeated from 3 to 9 days with each subject. Skin temp. at 16 points on the body surface and the pulse rates were noted. The difference between the figures of the first and second measurements of basal metabolism was slight and indicates that with normal persons, prolonged rest in bed prior to measurements in the morning is unnecessary provided the usual half-hour rest period is insisted upon. Wide variations in skin temp. show the absence of a correlation between heat production and heat loss. The basal metabolism on any given day is fixed with a remarkable constancy.

L. W. RIGGS

Hemolysis studies. I. Mechanism of hemolysis by hydrogen and hydroxy ions.

RUDOLF MOND. *Arch. ges. Physiol.* (Pflüger's) 208, 574-94(1925); cf. *C. A.* 20, 443.—It must be assumed that the hemoglobin is present within the limiting plasma membrane in the substance of the red cell and that for agents to be hemolytic the normal impermeability of this membrane for the pigment must be altered. But if the hemolytic agent causes a change in the state of the hemoglobin of such a nature that the particles of hemoglobin become increased in size through aggregation or that they enter into a firm union with the colloids of the interior of the cell, hemolysis will be impeded despite the fact that the permeability of the membrane may be increased. Heat-coagulated hemoglobin, on the alk. side of its isoelec. point, is sol. in warm dil. alc., a characteristic which extends to an even higher degree to globin. With the latter even at the isoelec. point and on the acid side heat coagula are sol., although rather more slowly. In all instances, with cooling the process is reversible. The stroma of the blood cell has an isoelec. point on the acid side, the position of which varies, according to the salt concn. and the nature of the ions, between p_H 5.5 and 3.0. As the p_H leaves the isoelec. point, becoming alk., the vol. of the stroma increases and finally a soln. takes place. If these properties of the structural substance can be transmitted to the colloid of the plasma membrane it would be expected that with an approach to the isoelec. point an increasing flocculation would occur, leading to a loss in cohesion in the plasma membrane, so that with the extreme increase in permeability the hemoglobin would pass out. While a pronounced swelling may not entail a permeability of the plasma membrane for hemoglobin, the soln. of the colloid leads to a destruction of the membrane and thus to hemolysis. Expt. confirms this hypothesis. A slight increase in the H-ion concn. beyond the neutral point leads to the outpouring of hemoglobin, while on the alk. side there is a broad zone of resistance. From expts. involving time relationships it is clear that the changes in the stroma extend to the membrane colloids. The flocculation occurring in the neighborhood of the isoelec. point proceeds much more rapidly than does the dissolution associated with swelling, consequently hemolysis through the action of acids takes place much more rapidly than does that following treatment with alkalis. The shift in the point at which hemolysis begins to the acid side caused by increasing the salt concn. is due to a change in the isoelec. point of the stroma. In order to explain the differences in the resistance of blood cells to acids and alkalis it is necessary to consider the changes in vol. caused by the H and OH ions and the effect of the consequent increase or decrease on the internal substances of the blood cell which have osmotic properties. AcOH and NH_3 , which penetrate the interior of the blood cells, behave much as do HCl and NaOH, the greatest difference in effect being that the NH_3 -treated cells hemolyze more rapidly. The changes in dispersion of the colloids of the plasma membrane take place so quickly that at a given p_H no difference in the behavior of AcOH and of HCl can be detected. In hemolysis with alc. and with ether the max. resistance occurs at the neutral point. In its effects on the blood cell the activity of saponin increases in proportion as the p_H is reduced. G. H. S.

Composition of blood serum and its significance for the action of toxins. I. Introduction. HANS HANDOVSKY. *Arch. ges. Physiol.* (Pflüger's) 210, 35-49(1925).—Introducing the following papers with a statement of the problems under consideration, viz., the relation of the proteins of normal sera to each other; the inter-relationship of the proteins in experimentally modified sera; the relation of the proteins to cholesterol and the phosphatides; and the importance of the state of the cholesterol of the serum as regards the tonic action of the latter for the isolated intestine of the cat. **II. Characterization of the protein fractions of normal sera through viscosity.** PAUL BOSSE AND HANS HANDOVSKY. *Ibid* 50-55.—Detns. made on bovine sera showed the protein relationships to be euglobulin : pseudoglobulin : albumin = 18 : 23 : 59. Thus a serum with 6.68% protein would have 3.91% of albumin + 1.54% of pseudoglobulin + 1.2% of euglobulin. The viscosity of a normal serum is an additive property of the individual protein fractions. **III. Effect of ether on serum.** PAUL BOSSE. *Ibid* 56-8.—Studies

on the relationship between the cholesterol and the proteins of sera render it essential to det. what effect Et_2O has on the protein constituents, and data are given indicating that it alters the pptn. reaction of the albumin by MgSO_4 , the amt. precipitable usually showing a progressive diminution as the extn. is continued; while the amt. of precipitable globulin may show a variable reaction, occasionally increasing progressively during the extn., but more commonly being lower after a short period of extn. and then increasing somewhat. **V. The state of the cholesterol in the blood serum.** HANS HANDOVSKY, KARL LOHMANN AND PAUL BOSSE. *Ibid* 63-9; cf. *C. A.* 20, 613. —In normal beef serum about 25% of the cholesterol is combined with globulin, the remainder being in association with the phosphatides. The intensity of the union, as detd. by shaking out with Et_2O , is dependent upon the salt and water content of the serum. The intensity with which the cholesterol of the serum is bound is of significance for its physiol. action. G. H. S.

Importance of inorganic ions for the contractility of smooth muscles; frog stomach. WALTER HEYMANN. *Arch. ges. Physiol.* (Pflüger's) 210, 187-208(1925).—Alkalies, as chlorides, in isotonic concns. may be arranged, in accord with their paralyzing action on the contractility of smooth muscle, in the series $\text{Na} < \text{Cs} < \text{Rb} < \text{K} < \text{NH}_4 < \text{Li}$. Frog stomach preps. show no sp. K paralysis; indeed Li seems to be the most active ion; in these points this muscle reveals effects quite distinct from those of striated muscle. As regards the action of the anions and the cations of the alk. earths the stomach preps. behave much as does skeletal muscle. The condition for the occurrence of ion action is primarily detd. by the contraction process. Swelling and contractility of the stomach strips are to a high degree independent of each other; there is no connection between the effect of salts in swelling and on contractility. From an isotonic cane sugar soln. cane sugar passes into the muscle, and the K content of the muscle is diminished up to about 50%. In K-poor salt solns. the prepn. loses K, without causing any material damage to contractility. The quant. relationships between the cane sugar intake and the K yield are not modified by multiple contractions. Holding the muscle, without stimulation, in an isotonic cane sugar soln. contg. 0.02 CaCl_2 scarcely modifies contractility, in spite of the sugar intake and the loss in K, but a single contraction in the sugar soln. is sufficient to damage the stomach muscle and render it irreversible. The onset of paralysis in Ca-free Ringer soln. is dependent on the contraction process. The smooth muscle cell of the frog stomach is permeable for Ca, its Ca content being in equil. with the Ca concn. of the surrounding fluid. G. H. S.

Effect of kidney substances on the heart and vessels. W. W. PETROWSKY. *Arch. ges. Physiol.* (Pflüger's) 210, 294-9(1925).—Ringer-Locke soln. which has passed through the kidney contains substances which significantly increase heart activity and possess vasoconstricting properties. These substances are thermostable and pass through the Berkefeld candle. G. H. S.

Choline as the hormone of intestinal motility. X. Choline content of the muscularis and the mucosa of the small intestine. H. SAWASAKI. *Arch. ges. Physiol.* (Pflüger's) 210, 322-33(1925); cf. Abderhalden and Paffrath, *C. A.* 19, 1910.—By using the same wt. of muscularis and mucosa-submucosa of the cat small intestine the amts. of choline to dialyze out within 1 hr. from the 2 tissues were in a ratio of 75:100. Occasionally the same amt. was derived from both tissues; in 1 instance the muscularis dialysate contained the greater amt. The choline of the intestinal musculature is not derived from postmortem decompn. processes in the mucosa. The total amt. of choline, derived through 1 hr. dialysis of 100 g. of cat tissue, is 1.6-4.3 mg. From 100 g. of rabbit tissue the amt. is 3-4 mg. G. H. S.

Notes on Sawasaki's paper: "Choline as the hormone of intestinal motility. X." EMIL ABDERHALDEN AND HANS PAFFRATH. *Arch. ges. Physiol.* (Pflüger's) 210, 620-2(1925); cf. preceding abstr. It is pointed out wherein the methods employed and results obtained by Sawasaki differ from those recorded by the authors. The difficulty of making direct comparisons under these circumstances is emphasized. G. H. S.

Blood coagulation. II. The time law. SUSUMU TSUNOO. *Arch. ges. Physiol.* (Pflüger's) 210, 334-42(1925); cf. *C. A.* 19, 324. —In the coagulation of oxalate plasma by thrombin derived from serum-casein, Fuld's time law is valid only within narrow limits, as is also the case for the Madsen-Walburn formula. In the coagulation of pure fibrinogen by thrombin the latter formula holds within a more limited range than does Fuld's time law. **III. Cataphoretic experiments with thrombin.** *Ibid* 343-50.—The reaction for the transport of thrombin derived from casein is p_H 4.5, for Alex. Schmidt's thrombin between p_H 5.0 and 5.7. The transfer of the thrombin is independent of the admixed proteins. G. H. S.

Carbohydrate loss of the liver in hyperthyroidized rats: Estimation of thyroid

preparations. TOMIO FUKUI. *Arch. ges. Physiol.* (Pflüger's) **210**, 410-26(1925).—Feeding with thyroid substance itself or with a no. of thyroid preps. causes a loss in the total carbohydrate of the liver of rats. The method of estg. the potency of thyroid preps. is based on the above fact. Thyroid feeding does not modify the carbohydrate content of the muscle, but upon the liver the effect persists for some days after the feeding is stopped. No parallelism between the activity in this direction and the I content of the preps. could be detected, although certain preps. with but little I proved to be inactive. Injections of Na had no effect on this carbohydrate loss of the liver. With iodallacid, an I-contg. protein compd., a definite reduction in liver carbohydrate occurred, but the I content of an effective dose of this prep. was many times that of the active dose of the thyroid preps. G H S

Heat regulation. VIII. **Reduction in water output through the skin by reducing the fluid intake.** ERICH SCHLÜTER. *Arch. ges. Physiol.* (Pflüger's) **210**, 432-5(1925).—With inadequate water intake the output of water through the skin is diminished. Disturbances in heat regulation may occur in summer with its higher temps. and increased bodily activity if the intake of water is inadequate for an abundant formation of sweat. G. H. S.

Ionic antagonism in hemolysis. D. ALPERN. *Arch. ges. Physiol.* (Pflüger's) **210**, 442-9(1925).—NaCl and KCl, like NaCl and CaCl₂, when mixed in the proper proportions inhibit hemolysis to a greater degree than do solns. of the salts singly. This antagonistic effect is directly dependent upon the H-ion concn. of the material in which the red blood cells are suspended, in such a way that in all cases with a slight departure from the neutral point on the acid side or by an approximation to the isoelec. point of the surface plasma colloid this effect immediately disappears. The antagonism between Na and K is most evident at a neutral reaction. It vanishes in a weakly alk. reaction, only to appear again as the OH concn. is still further increased. The optimum relation between Na and K is displaced in a strong alk. reaction, to the advantage of the K. The greatest antagonistic action between Na and Ca is manifested, in a weakly alk. reaction, rather than at the neutral point. As the OH concn. is further increased the antagonism disappears and does not reappear as is the case with Na and K. KCl and CaCl₂, mixed in different proportions, show no definite antagonism at any of the H-ion concns. studied. Likewise, the admixture of 2 anions failed to reveal an antagonistic effect. G. H. S.

General cellular physiology. IV. **Neutrality regulation by erythrocytes and musculature. The permeability problem.** ERNST GEI Horn AND KURT WEIDLING. *Arch. ges. Physiol.* (Pflüger's) **210**, 492-513(1925); cf. *C. A.* **19**, 2846.—Changes in the neutralization velocity in the red blood cell do not follow variations in the time or temp. of the expt. except in alk. solns. The neutrality regulation of the red cell is independent of the compn. of the nutritive soln. from either the chem. or physico-chem. point of view. The replacement of NaCl by other cations (Ca) is without effect. Adrenaline is also ineffective. It is assumed that this condition is detd. by the small vol. of the blood cell, since diffusion processes can proceed so quickly that variations in the velocity of the neutralization cannot be detected. Reactions with gelatin support this hypothesis, for if the gelatin is finely pulverized variations in the duration of the expt. and in the temp. do not alter neutrality; but if gelatin plates 0.2 mm. in thickness are used, the neutralization increases with time and with temp. On the contrary, the magnitude of the neutrality regulation is dependent: (1) on the p_H of the soln., in that the further this is removed from the neutral point on either side, the more is the p_H shifted by the blood cells; and, (2) by internal conditions, since by aging the neutrality regulation is strengthened. With muscle the neutralization of the soln. is based on a slowly progressing process of diffusion, which increases with time and temp. Neutralization velocity is dependent upon the conditions of the colloidal limiting layers. It is inhibited in increasing degree according to the series $Li < Na < K, Ca$. By adrenaline and choline it is reduced; by a hypertonicity of the soln., or by elec. stimulation of the muscle, it is increased. In small doses narcotics reduce it; in high concns., which lead to an irreversible paralysis, it is increased. If the soln. in which the muscle is found is repeatedly changed the neutrality regulation is more pronounced than if the muscle is allowed to remain for the same length of time in the same fluid. Here it is probable that with the modification in the limiting layers of the muscle, there is an increased diffusion velocity and especially a favoring of neutrality regulation. G. H. S.

Occurrence of two different types of glucose disappearance in human blood corpuscles and their inter-relationship. HANS HÄUSLER. *Arch. ges. Physiol.* (Pflüger's) **210**, 561-5(1925).—When the glucose of the surrounding fluid amounts to between

0.2 and 1.0% human blood cells adsorb approx. the same percentage of the glucose. A certain part of the adsorbed glucose disappears from the whole blood instantly, and this "initial disappearance" is the smaller as the amt. of glucose adsorbed is less. The glucolysis is the smaller, when the initial disappearance is the greater and *vice versa*. In contrast to the glucolysis the initial disappearance is instantaneous and is instantly completed. It also takes place at room temp. The susceptibility to NaF and to oxalate has a relationship to the glucolysis. G. H. S.

Extension and loading of skeletal muscle in acetylcholine contraction and in tetany. OSCAR WYSS. *Arch. ges. Physiol.* (Pflüger's) **210**, 586-97(1925).—The max. acetylcholine contracture attains a shortening of an av. of 11% of the resting length of the muscle, the extension of the resting length requiring a tension of some 40 g. For maximal tetany the corresponding values amount to 32% and 400 g. For acetylcholine contraction the max. shortening is about 3 times less and the tension some 10 times less than the corresponding values in max. tetany. Acetylcholine contraction and submaximal tetany of the same degree of shortening require about the same amt. of tension and under favorable conditions the extension curves closely parallel each other. G. H. S.

Formation of ammonia in infants. M. LANDSBERGER. *Z. Kinderheilk.* **39**, 586-96(1925).— NH_3 formation is increased by fermentative processes occurring in the colon, and very frequently, but not always, the actual and potential urinary acidity is increased. G. H. S.

Excretion of organic acids in the urine of infants. M. LANDSBERGER. *Z. Kinderheilk.* **39**, 597-607(1925).—The excretion of org. acids is very definitely connected with the protein content of the nourishment; the injection of human milk only causes the urine to contain less than does human milk and plasmon or artificial feeding. The higher acid excretion when on a cow milk diet may be due to the higher protein content or to the compn of the milk. According to the present conception fat is to be considered as the most important acid former which in rickets leads to a marked increase in the org. acids in the urine. Concn. or diln. has no effect on the excretion of org. acids. G. H. S.

Effect of ions on diuresis in infants. I. FREUDENBERG. *Z. Kinderheilk.* **39**, 608-12(1925).—The anions phosphate, chloride and bicarbonate have a marked effect on diuresis, phosphate causing a definite retention, bicarbonate a pronounced increased excretion, and chloride holding an intermediate position. The cation K has diuretic properties. H ions and OH ions modify diuresis in that acidosis causes increased output; alkalosis causes retention. The effects of altering the reaction of the urine upon the urinary output are simple reactions. G. H. S.

G—PATHOLOGY

H. GIDEON WELLS

The capacity to oxidize carbohydrate as determined by the respiratory quotient. H. B. RICHARDSON. *Ergebnisse Physiol.* **24**, 588-93(1925).—The ability of the organism to oxidize carbohydrate is better detd. by observation of the respiratory quotient than by the glucose tolerance test or by following the blood sugar after glucose ingestion. On administration of carbohydrate to a normal man there is a prompt rise in the respiratory quotient to the level of unity while no change over the prevailing respiratory quotient occurs when glucose is given to a patient in diabetic coma. However, in a patient with exophthalmic goiter and one with renal diabetes both of whom had a glucosuria, there was a prompt oxidation of ingested glucose, indicating that the glucosuria of these 2 diseases has no necessary relation to diabetes melitus. H. J. D., Jr.

Hemolysin in malaria. WALTER KIKUTH. *Arch. Schiffs-Tropen Hyg.* **29**, 560-4 (1925).—Contrary to existing views, K. finds no hemolysin in the blood from malaria patients. FRANCES KRASNOW

The immunological properties of alcohol-soluble vegetable proteins. J. H. LAWIS AND H. GIDEON WELLS. *J. Biol. Chem.* **66**, 37-48(1925).—"Immunological study of the alc.-sol. proteins from certain cereal grains indicate that they fall into 2 classes. Gliadin from wheat and rye and the prolamines from durum, einkorn, emmer and spelt, of the genus *Triticum*, seem to be very closely related, according to tests by means of both the complement-fixation and the anaphylaxis reaction. The alc.-sol. proteins from common maize, from kafir corn and from teosinte were found to be closely related to one another, but not to the alc.-sol. proteins of the *Triticum* group. These results agree with observations made by Gortner and Hofmann that the chem. properties of these alc.-sol. proteins indicate the existence of a 'wheat group' and a

'corn group' of prolamines, the members of each group being chem. similar to each other, as they have been found to be immunologically." A. P. LOTHROP

Clinical calorimetry. XXXIX. Exercise and the respiratory quotient in diabetes. H. B. RICHARDSON AND S. Z. LEVINE. *J. Biol. Chem.* 66, 161-83(1925); cf. C. A. 19, 2237.—Six diabetics and 2 controls were studied in the post-absorptive state after exercising lightly for about 30 min. The respiratory quotient was depressed below the basal level in the exercising diabetic individuals, indicating that the diabetic, by reason of the fundamental defect of the disease, is unable to increase the oxidation of carbohydrate to the same extent as fat. This inability was not caused by a lack of available carbohydrate as the patients having the highest blood sugar showed the least oxidation of carbohydrate on exercising. "From a review of the available evidence the conclusion is drawn that fat can be oxidized in the mammalian organism without previous preliminary conversion into carbohydrate." A. P. LOTHROP

Ochronosis. Report of a case with associated disease of the adrenals. W. C. HUNTER. *Ann. Clin. Med.* 4, 250-9(1925). JOHN T. MYERS

Calcium deficiency in asthma, hay-fever and allied conditions. G. T. BROWN AND O. B. HUNTER. *Ann. Clin. Med.* 4, 299-306(1925).—Many cases of asthma, hay-fever, eczema, etc. have a definite Ca deficiency. This can be remedied by feeding Ca lactate, thyroid, or parathyroid; or by the quartz lamp. This is an aid to protein desensitization. JOHN T. MYERS

Non-specific stimulation of a natural antibody. T. J. MACKIE. *J. Hyg.* 24, 176-88(1925).—The natural hemolytic antibody of the rabbit for sheep blood is quite const. Successive large bleedings may increase the antibody content but small bleedings have no effect. The increase is less than that following injection of homologous or even heterophile antigen. JOHN T. MYERS

The effect of hemorrhage on the hemolytic titer of the serum of rabbits. J. MILLS. *J. Path. Bact.* 28, 579-89(1925).—Repeated bleedings caused a fall in hemolysin content of the blood with a subsequent rise. JOHN T. MYERS

Complement fixation with bilharzia. I. The lipoidal nature of cercarial antigen as used in the complement-fixation test for mammalian bilharziosis. N. H. FAIRLEY. *J. Path. Bact.* 28, 591-607(1925).—The % of alc. by vol. in an antigen made by extg. fresh cercarial infested livers of snails was 96.65%. Its residuc failed to give the biuret Hopkins-Cole, ninhydrin, or Millon reactions for protein. Powdered cercarial livers extd. with abs. alc. gave an antigen effective at a diln. of 1 to 600. Treatment with dry acetone and subsequent extn. with abs. alc. gave a highly specific antigen. The syphilitic antigenic property could be dild. out. The antigenic factor was practically completely removed by repeated extn. with alc. Apparently the antigen is a lipid, not a protein. JOHN T. MYERS

Liver necrosis and cirrhosis produced experimentally by coal tar. J. DAVIDSON. *J. Path. Bact.* 28, 621-6(1925).—Coal tar applied to the ears of rabbits or injected subcutaneously in ethereal soln. causes necrosis of liver cells. The acute stages resemble acute yellow atrophy and the chronic condition resembles atrophic cirrhosis. This suggests that acute and subacute yellow atrophy and atrophic cirrhosis are stages in the same process. The regenerated tissue is still susceptible to the irritant. The arrangement of the regenerated tissue is irregular and in some instances adenomatous. JOHN T. MYERS

The pathogeny of rickets. LÉON BLUM, MAURICE DELAVILLE AND VAN CAULAERT. *Pressu médicale* 33, 801(1925); *Bull. soc. hyg. aliment.* 13, 462; cf. C. A. 19, 1159.—The normal course of ossification is related to an acid-basic equil., with basic predominance, as it exists in normal subjects. Displacement of the equil. towards acidity involves ossification troubles (by change in the reaction of the proteic colloids). Seric hypophosphatemia is considered to be a consequence of acidosis: the excess of CO₂ in the blood causes part of the P in the blood plasma to pass into the red globules. If the acidotic trouble occurs while the bones are still in the course of development, it results in rickets owing to lack of ossification of the osteoc tissue and resorption of the bony tissue already formed; if it occurs in adults with completely formed skeleton, there is a decalcification of the bony tissue (osteomalacia). A. PAPINEAU-COUTURE

Effect of electrically charged dyes on the agglutination and on the formation of agglutinins. P. SZRÖP. *Magyar Orvosi Archivum* 26, 393-8(1925).—Dyes with positive elec. charges cause an increase and the same with negative charges cause a decrease of the agglutinating titer of immune serums. These factors have effects exactly opposite to the above mentioned upon the formation of agglutinins. Effect of radium α -rays upon the titer of agglutinating serums. *Ibid* 399-400.—Serums treated with Ra α -

rays show an increase of the agglutinating titer, probably by increasing the positive charge of the agglutinins.

L. W. RIGGS

Stalagmometry in connection with liver function. F. SOMMER. *Arch. expl. Path. Pharm.* 109, 50-63(1925).—While stalagmometric results based on detn. on urine and on serum must be considered to lack specificity, it is certain that the surface tension of the serum is depressed somewhat in proportion to the degree of disturbance in liver function. In mild or only moderately severe cases the reduction in the drop no. of the serum is due primarily to the bile acids. Here, stalagmometry permits an estn. of the degree of the cholemia. In severe cases with a more outspoken derangement in liver function the serum shows a considerably reduced surface tension the cause of which must be referred to other factors as well (pathol. protein decompn.). Tests of the surface tension changes may serve to differentiate cases of cholemic icterus from cases with damage to the parenchyma.

G. H. S.

Calcium-ion concentration of the blood in puerperal eclampsia. RICHARD V. BODÓ AND STEPHAN LIEBMAN. *Arch. expl. Path. Pharm.* 109, 178-84(1925).—As regards action on the frog heart the sera of eclamptics behaved just as does sera taken during normal pregnancies.

G. H. S.

Chemical study of the specific elements of tuberculin. I. J. HOWARD MUELLER. *J. Exptl. Med.* 43, 1-8(1926); cf. *C. A.* 19, 1736.—The sp. precipitin reaction and the skin reaction given by old tuberculin are attributable to 2 sep. substances present in the material. The cause of the reaction first mentioned is a non-protein gum. The cause of the skin reaction is probably but not surely a protein. Methods which have been suggested for the standardization of tuberculin by precipitin or complement fixation reactions should be revised. II. **The preparation of residue antigen from old tuberculin.** *Ibid.* 9-12.—A non-protein gum has been isolated from broth filtrates of human tubercle bacilli grown on a simple medium. It fixes complement and ppts. in high dilution in the presence of homologous immune sera, but fails to give a skin test in tuberculous animals. The prepn. and some of the chem. properties of the substance are described.

C. J. WEST

Production of albuminuria by renal vasoconstriction in animals and in man. ISAAC STARR. *J. Exptl. Med.* 43, 31-51(1926).—Transient albuminuria follows the infusion of small doses of adrenaline into rabbits, if prolonged over several minutes. Agents causing renal vasoconstriction also cause transient albuminuria in anesthetized, eviscerated dogs. Cats eliminate albumin after having been frightened or enraged. The drug, ephedrine, which commonly causes renal vasoconstriction in animals, has been tested in man. Transient albuminuria followed its administration, in those cases in which signs of renal vasoconstriction appeared; it did not in those cases in which such signs were lacking. Ephedrine is not intrinsically injurious to the kidneys.

C. J. WEST

Stability of the acid-base equilibrium of the blood in pregnant animals. WM. DEB. MACNIDER. *J. Exptl. Med.* 43, 53-9(1926).—The acid-base equil. of the blood as indicated by detns. of the reserve alkali of the blood remains const. in non-pregnant animals at different age periods. This does not imply that the acid-base balance of such animals at different age periods is a stable balance. In pregnant animals of the same age periods as the control animals there may develop an instability of this equil. which is either associated with the occurrence of a renal injury and which may be looked upon as a retention phenomenon, or arises independently of such an injury. In this latter group of animals the disturbance in the equil. increases in frequency and is earlier in its appearance in the gestation period as the age of the organism increases. In old and in senile pregnant animals some physiol. mechanism other than of the kidney becomes unable to stabilize the acid-base equil. of the blood with the result that as the pregnancy advances this physiol. state of the organism (gestation) becomes pathol.

ALFRED N. RICHARDS

General pathology of poisoning by war gases. A. LUSTIG. *Sperimentale* 79, 847-69(1925).

M. HEIDELBERGER

Chemical excitability of the cerebellar cortex. G. SIMONELLI. *Rend. d. adunanze dell'accad. med. fis. fiorentina; Sperimentale* 79, 901-6(1925).—A discussion of the asymmetry produced by application of strychnine sulfate to a portion of the *crus primum* of cats decerebrated above the thalamus.

M. HEIDELBERGER

The effect of X-rays on the irritability of muscles in the frog. I. KUSENER. *J.*

Gen. Physiol. 9, 55-61(1925).—Frog muscle which has been exposed to X-rays maintains its irritability better than non-exposed muscle as shown by its response to smaller elec. stimuli. C. H. R.

Clinical study of quinidine therapy. H. H. RIECKER. *Am. J. Med. Sci.* 170, 205-12(1925).—Normal rhythm was restored in 79% of 52 cases of auricular fibrillation. G. H. S.

Pharmacology of body position and the labyrinthine reflex. XIX. Morphine. ERNST JOEL AND FRITZ ARNDTS. *Arch. ges. Physiol.* (Pflüger's) 210, 280-93(1925); cf. *C. A.* 20, 456.—Doses of morphine of 0.1-0.2 mg./kg. cause a stage of light narcosis, which represents only a phase of the complete intoxication picture. In thalamus animals (both cats and rabbits) morphine in doses which do not disturb coördination in the slightest in the intact animal cause restlessness and strychnine-like reflex convulsions. Thalamus rabbits are about 10 times as susceptible to morphine as are intact rabbits. In cats there occurs as a distinctive feature a simultaneous morphine rigor. If the mid-brain is removed from either cats or rabbits, doses of morphine which cause convulsions in thalamus animals cause no changes aside from a tendency to increased activity. Only after large doses do decerebrate animals show convulsions. These are independent of the respiration, since, as in thalamus cats, they are not prevented by artificial respirations. G. H. S.

Humoral transmissibility of heart-nerve action. IX. Camphor and the vagus. E. NAVRATIL. *Arch. ges. Physiol.* (Pflüger's) 210, 550-6(1925).—The initial effect of camphor, or camphor in small doses, increases the irritability of the vagus, while large doses are inhibitory. G. H. S.

I—ZOOLOGY

R. A. GORTNER

Biochemistry of the wild silk-moth, *Dictyoploca japonica*, Moore. I. Chemical development in the growth of the wild silk-moth. OSAMU SHINODA. *Mem. Coll. Sci. Kyoto Imp. Univ.* (reprint) 9A, No. 3, 225-35(1925).—Chestnut leaves during growth show a decrease in the content of water, total N, ether- and water-sol. constituents and ash and an increase in the water-sol. N, polysaccharides and fiber material. Unlike *Bombyx mori* the caterpillars of *Dictyoploca japonica* fed on these leaves show a fairly const. N content, perhaps on account of the lesser development of the silk glands. After cocooning the N unexpectedly rises from 1.2 to 10.4%. The relative shortness of the larval stage and consequently of the gonadal development during this period may account for the relatively slight glycogen metabolism. The sudden decrease of water-sol. matter at the onset of pupation may be related to the fat metabolism.

MARY JACOBSEN

Studies on the comparative physiology of contractile tissues. I. The action of electrolytes on invertebrate muscle. L. T. HOGREN. *Quart. J. Exptl. Physiol.* 15, 263-312(1925).—The heart of the crustacean behaves towards Ca in a manner some what different from that described for *Limulus*. The removal of Ca in the absence of K leads to systolic standstill and excess Ca leads to diastolic stoppage, both effects being rapidly and completely reversible. Excess K at first excites and then depresses as in amphibian skeletal muscle. A slight increase has the same effect as increasing the Na/Ca ratio. Rb action closely resembles K but Cs has very little effect on the cardiac rhythm of *Homarus*. Stoppage of the heart due to excess K or Ca is accompanied by cessation of elec. response. Mg and Sr, in sufficient quantity, produce standstill, but it is impossible to maintain the beat when either is substituted for Ca. Ba has the opposite effect. Acidity of the medium produces primarily an increase in diastolic tone which appears to be independent of the lipid soly. of the acid used. The nail (*Helix*) and pecten heart is affected by small increases in K in a similar manner to other types of plain muscle. K removal does not produce tonic contraction as in the mammalian plain muscle. *Helix* and pecten hearts beat for a considerable time in K absence. Behavior of *Helix* to Ca is like that of the crustacean; the reverse is true of pecten. The acidity effects in *Helix* depend on the K/Ca ratio (possibly Na/Ca). The response of the surviving crop of *Aplysia* and *Helix* to changes in the Ca/K ratio of the medium is like that of the heart of *Helix*. Mg addn. resembles Ca in depressing the musculature tone of the *Aplysia* crop. Sr has the opposite effect and resembles Ba. Response of *Aplysia* crop to K, Rb and Cs is similar to mammalian preps. Both *Aplysia* and *Helix* crop are less sensitive to H ion than mammalian plain muscle. Good bibliography.

FRANCES KRASNOW

Temperature characteristic for locomotor activity in tent caterpillars. W. J.

CROZIER AND T. B. STIER. *J. Gen. Physiol.* **9**, 49-54(1925).—The frequency of abdominal peristaltic locomotor waves in *Malacosoma americana* larvae during vertical ascension is controlled by temp. according to Arrhenius' equation. The const. $\mu = 12,200$ is in quant. agreement with that obtained for other non-respiratory rhythmic neuromuscular movements among arthropods. C. H. R.

Temperature and the mechanism of locomotion in Paramecium. O. GLASER. *J. Gen. Physiol.* **9**, 115-21(1925); cf. C. A. **19**, 1871.—Rate of locomotion in *Paramecium* is governed by temp. according to Arrhenius' formula. Above 15° , $\mu = 8000$; below this temp. the value for μ is probably 16,000. A theoretical interpretation, in terms of a catenary series, is given. C. H. R.

Heat production of eggs of *Arbacia punctulata* during fertilization and early cleavage. C. G. ROGERS AND K. S. COLE. *Biol. Bull. Marine Biol. Lab.* **49**, 338-52(1925).—The rate of heat production at the instant of fertilization is 10 to 12 times that of the unfertilized egg. After fertilization the rate of heat production decreases constantly for 20 min. when it reaches about 65% of its fertilization value, and remains const. until the first cleavage at about 50 min. after fertilization. At the first cleavage the rate drops suddenly by more than 10% and then remains const. until the eggs are in the 8-celled stage, which is as far as the work has been carried. The rate of heat production of the unfertilized eggs is about 0.08 cal. per hr. per million eggs, and that of fertilized eggs about 0.52 cal. per hr. per million eggs after the 1-celled stage. It is suggested that the heat evolution occurring immediately upon fertilization is the result of an oxidative process which takes place chiefly in the cortex of the egg and which leads to the elevation of the fertilization membrane. L. W. RIGGS

Physiological studies on hibernation in the potato beetle, *Leptinotarsa decemlineata* Say. D. E. FINK. *Biol. Bull. Marine Biol. Lab.* **49**, 381-404(1925).—Beetles fed on non-solanaceous foods do not hibernate but die of starvation. Respiratory metabolism detns. show that the O consumption of beetles fed on tubers or fruit of solanaceous plants is less than that of beetles fed on foliage. A reduced CO_2 output occurs throughout the progress of hibernation. Prepn. for hibernation follows a period of extensive feeding and consists in an accumulation of fat and the loss of water. The elimination of waste products from the digestive tract is checked and the metabolic activity is lowered. The greatest depletion of fat and the lowest respiratory quotient occur during the first few months of hibernation. There appears to be a parallelism between a rapid depletion of reserve food and a low quotient. Recovery appears to vary inversely as the time of hibernation. Actual contact with water seems necessary to restore the water content before feeding is possible. Catalase activity of hibernating beetles is greatly reduced as compared with that of active beetles. There appears to be a correlation between reduced catalase activity and diminished respiratory metabolism in hibernating and starving animals. L. W. RIGGS

Feeding reactions and digestion in the coral polyp *Astrangia danae* with notes on its symbiosis with zoöxanthellae. H. BOSCHMA. *Biol. Bull. Marine Biol. Lab.* **49**, 407-35(1925).—Four reactions are noted: muscular action of the tentacles, muscular action of the central part of the oral disk, secretion of mucus by the oral disk and ciliary action of the stomodeum. The reaction of the food vacuoles in the digestive region of the mesenteric filaments immediately after feeding is acid; after about 2 days the reaction changes to alk. In this alk. period in all probability digestion takes place. Beside intracellular digestion a secretion of a digestive fluid (a trypsin-like enzyme) occurs. In the polyps of *Astrangia* which contain zoöxanthellae in their endoderm these unicellular algae furnish part of the normal food of the polyps. These algae are digested in the mesenteric filaments. L. W. RIGGS

A study of the secretion of the silk worm by aid of filtered ultra-violet rays (Wood's light). A. POLICARD AND A. PAILLOT. *Compt. rend.* **181**, 378-80(1925).—Silk worms during the 4th and 5th days of the 5th age of larval life, or when about ready to spin cocoons, show remarkable fluorescence under Wood's light. A large no. of facts relating to this phenomenon are recorded, but its exact cause remains obscure. Poorly nourished larvae or those in physiologic discomfort show little or no fluorescence, consequently the fluorescent test may be employed to select vigorous larvae, particularly for reproductive purposes. L. W. RIGGS

The relative toxicity of the arsenates of Ca [to insects] (HENDRICKS, *et al.*) **15**.

12—FOODS

W. D. BIGELOW AND A. E. STEVENSON

The calcium oxide content of some Philippine foods. F. T. ADRIANO AND E. J. TAVANLAR. *Philippine Agr.* 14, 347-58(1925).—Nearly all foods commonly used in the Philippines were analyzed for CaO, H₂O and ash. Averages obtained from 2 to 18 detns. on each material are tabulated.

Unification in the control of foodstuffs from the industrial viewpoint. NEUBAUER. *Chem.-Ztg.* 49, 893(1925).—N. suggests unified official control in Germany instead of the four present agencies in the supervision of industry. For food chemists a 5-year course with 1/2 year of law and 1 year of factory practice and for officials four years of chemistry with two years of factory practice are recommended.

Chemistry of bread. Some New Zealand wheat-flours and fermentation. W. L. M. DEARSLEY. *New Zealand J. Sci. Tech.* 8, 34-8(1925).—Analysis and baking tests of 5 strains of New Zealand wheat support the conception that an ideal flour is that which possesses a high proportion of gluten and which, on doughing, will produce in its dough a p_H as near 5 as possible and show that: the dough possessing the higher initial p_H ferments more slowly than that with a lower one; though color is partly dependent on the fat content of the flour, the "quality" of the fermentation is the chief detg. factor of color and texture of the loaf; the vol. of the loaf is the outcome of its H₂O-absorption capacity; losses of wt. in the loaf on keeping and in the dough on baking are due to loss of H₂O, which loss is apparently greatest, on the whole, from that loaf whose flour contains gluten of poorer quality.

Lactose determination in bread. W. SCHUT AND L. E. DEN DOOREN DE JONG. *Chem. Weekblad* 22, 518-20(1925).—The Dutch official method for the detn. of milk in milk bread consists of a detn. of fat. The latter, however, can be due to adulteration with butter. In a series of expts. the lactose detn. by the fermentation method of Kluyver gave reliable results. By a suitable choice of yeasts the total monoses are detd. in 1 sample of the aq. ext. of bread, while in another all monoses except lactose are fermented. The difference represents the lactose.

Identification of bleached flour. E. ARBENZ. *Mitt. Lebensm. Hyg.* 16, 200-1(1925).—The reaction of Griess-v. Ilosvay is recommended. Prepn. of the reagent and its application are described.

Can conservative pasteurization be ascertained by testing for cow milk diastase (amylase)? W. WEDEMANN. *Z. Fleisch und Milchhyg.* 35, 301; *Arb. Reichsgesundheitsamtes* 56, 359-62(1925).—Conservative pasteurization of milk consists of 0.5 hrs. heating to 60-63°. The absence of diastase in a milk does not necessarily indicate previous pasteurization since diastase is destroyed by 0.5 hr. heating to 56° and greatly reduced in its activity by exposure to 53-54°.

Some factors concerning the "partial neutralization" of cream for buttermaking. B. A. STIRITZ AND H. A. REUHE. *J. Dairy Sci.* 8, 459-85(1925).—The effect of various limes, soda ash and NaHCO₃ in neutralizing cream was studied on the quality, fresh and on storage for 30, 60 and 90 days, of the resulting butter, and on the fat losses in the buttermilk. Cream was neutralized at 32-38° to 0.2% acid, then pasteurized by holding 15 min. at 71°, then churned. Lime suspensions of 10-25% and soda ash and bicarbonate solns. of 5-20% were used. The weakest solns. gave the best butter and least fat loss, also better than unneutralized controls. The time required for neutralization was 1-2 min. for the soda, 4-5 min. for straight limes and 10-15 min. for magnesia limes. Loss of butterfat was greatest with soda ash, av. with NaHCO₃, still less with limes, and least with magnesia limes. *Reduction of acidity on pasteurization was 0.02-0.03% with limes, 0.05-0.06% with magnesia limes, and 0.07-0.075% with soda. Soda ash butter scored high fresh but deteriorated more rapidly. NaHCO₃ gave a bicarbonate flavor and magnesia limes a flat flavor. There was not much difference between individual neutralizers but mixts. of 2 or more scored off.

Keeping quality of sweet cream butter as affected by temperature of pasteurization of the cream. WM. WHITE AND G. R. CAMPBELL. *J. Dairy Sci.* 8, 497-9(1925).—In 116 churnings of sweet cream butter, cream was pasteurized for 25 min. at 63°, for 30 min. at 63°, 65.5° and 68°, and for 30 min. rising from 63° to 68°. Samples of the butter were stored at -18° for 7 1/2 to 9 months. "Scores of the butter after storage indicate the keeping quality was not influenced by these temps. of pasteurization of the cream."

The effect of homogenization, condensation and variations in the fat content of a

milk upon the keeping quality of its milk powder. G. E. HOLM, G. R. GREENBANK AND E. F. DEYSHER. *J. Dairy Sci.* **8**, 515-22 (1925).—Fresh, cooled milk samples were standardized for fat, pasteurized at 60–65° for 30 min. and spray dried. The powder of approx. equal moistures was sealed in cans and stored at room temp. The cans were opened at intervals up to 5 months and either smelled for tallowness or tested for the time required to absorb O at 70°. Condensing and homogenizing both favored keeping qualities. Condensing probably removes volatile substances which are catalysts. Fat not covered by protein (CCl₄ ext.) increased with the fat content of the powders and decreased the keeping qualities. As the fat content of the powders increased so the keeping qualities diminished.

F. L. SEYMOUR-JONES

Relation between the gold number of gelatin and its value in the ice cream mix. H. C. MOORE, W. B. COMBS AND C. D. DAHLE. *J. Dairy Sci.* **8**, 500-11 (1925).—Six samples of gelatin were tested for gold no., pH, ash and moisture content, bacterial count, swelling strength, soly., gel strength (Burke method), jelly value and viscosity. No relationship existed between gold no. and the other tests, nor between gel strength and amt. of gelatin to be used. Ice cream contg. gelatin retained air longer. The amt. of gelatin to be used is best judged by a standing up test at room temp.

F. L. SEYMOUR-JONES

Simplified method of determination of coconut butter in margarine. S. H. BERTRAM, J. P. K. VAN DER STEUR AND F. VERHAGEN. *Chem. Weekblad* **22**, 549-50 (1925).—While pptg. the Mg salts stir with an electrically driven stirrer and continue at 70–80° for 10 min. after pptn. The MgSO₄ soln. can be run in at once. A few min. standing at 20° is sufficient.

MARY JACOBSEN

The composition of the milk of cows in heat. J. STERN. *Z. Nahr. Genussm.* **50**, 225-7 (1925). Analyses are given of the milk of 12 cows of various breeds during and after heat. The figures show that there would be no suspicion of diln., rather in some cases there is an increase in % of fat and a decrease in the amt. of milk.

WILLIAM J. HUSA

Drying industry. IV. The manufacture and drying of blood and slaughter house by-products. MAX WINCKEL. *Chem.-Ztg.* **49**, 957-8 (1925); cf. *C. A.* **19**, 1915.—The following products are handled: *whole blood, coagulum* (whole blood coagulated), *defibrinated blood, blood serum, fibrin, blood residue*. In the cool season of the year, fresh whole blood is worked up as *black pudding*, any excess being dried. For fertilizer and fodder, the blood is defibrinated and coagulated by heating with the addn. of small quantities of AcOH. The coagulum is transferred to a vessel in which the coagulated albumin remains and the liquid flows off. The coagulated material is then dried in a *barrel or drum drier* with the addn. of sawdust or peat if it is to be used for fertilizer or straw or hay if it is to be used for fodder. For sepn. of serum the blood is placed in large vessels and the serum drawn off at the bottom. This seps into 2 layers on standing, the upper layer clear (*Serum I*), and the lower more or less red colored (*Serum II*). The colored residue is mixed with H₂O and again sepd., a very dark product (*Serum III*) being obtained. Centrifuges are sometimes used. Dr. Steinitzer of Osterwieck has patented a machine which produces nearly 100% yield of high-grade serum. Turpentine oil or a mixt. of AcOH and H₂SO₄ is used for clarification. Blood serum is used as a com. article in the form of small cryst. plates, obtained by drying on glass or enamel plates in a *Horden or canal drier*. Serum albumin or blood albumin is used in large quantities in print works and dye houses as an insol. binder for colors, in the photographic industry, as a clarifying agent, and as a substitute for casein. Blood which has not been coagulated but has been defibrinated can also be used for making dried blood, and this type is used in the arts. It is dried in a vacuum drier. The fibrin albumin produced by defibrination is used for making *peplone* and is dried in a vacuum drier. Other slaughter house products are the various glands: *thyroid, ovaries, pancreas, testes*, etc., all used in the pharmaceutical industry. In former times the organs contg. these glands were removed, salted or treated with preservatives and perhaps held for weeks. Now the fresh organs are finely pulverized and dried in a vacuum drum, none of the constituents of the glands being destroyed and none of the therapeutic properties lost. There is also the *digestive tract*, rich in digestive enzymes and making valuable addns. to fodder used for calves and young pigs. About 10% of this material is added to the fodder, the whole placed in a silo and allowed to ferment at 40° for 36 hrs. It is then dried below 65° in a vacuum or drum drier.

H. STOERTZ

Refractometry as an aid in research on fruit juices. HANNS ECKART. *Z. Nahr. Genussm.* **50**, 196-204 (1925).—Refractometry offers a means of detecting added H₂O in fruit juices. Since a low refraction may be the result of fermentation, a low reading must be confirmed by an alc. detn.

WILLIAM J. HUSA

A new reagent for tannic acid in fermented vinegar. G. REIF. *Z. Nahr. Genussm.* 50, 192-5(1925).—The reagent consists of 3 g. of Na tungstate, 2 g. of Na phosphate and 0.05 g. of molybdic acid dissolved in 25 g. of water by gentle warming, the soln. being cooled and neutralized to litmus by concd. HNO_3 . To 10 cc. of vinegar is added 0.5 cc. of 10% HCl and 1 cc. of the reagent. The mixt. is heated to boiling and then allowed to stand at room temp. In presence of tannic acid a violet color appears, reaching max. intensity after about 2 hrs. The test is sensitive to 1 part of tannic acid in 500,000.

WILLIAM J. HUSA

The direct and indirect determination of dry residue and the determination of sugar in vinegar. G. REIF. *Z. Nahr. Genussm.* 50, 181-92(1925).—The indirect method of Lehmann and Gerum (cf. *C. A.* 6, 1940) gives unobjectionable results for fermented vinegars, especially for wine, apple, raspberry and malt vinegars. For detn. of sugar it is advantageous to use the iodometric method (cf. *C. A.* 17, 512).

W. J. H.

Cacao beans and cacao products. HEINRICH FINCKE. *Z. Nahr. Genussm.* 50, 205-20(1925); cf. *C. A.* 19, 684.—Numerous analyses of cacao beans and various cacao products are presented and discussed. Adulteration of cacao butter with the fat of the shells or embryo may be detected by the resulting high acid no.

WILLIAM J. HUSA

The dispersion of powdered egg yolk. ROSALIE M. COBB AND F. S. HUNT. *J. Am. Leather Chem. Assoc.* 21, 18-22(1926).—Powd. egg yolk can be worked up into an emulsion with water as good as that of liquid egg yolk used in fat liquoring provided enough alkali is incorporated to bring the p_H value to 8.6. The use of an alk. preservative for powd. egg yolk is suggested.

J. A. WILSON

The testing and judging of desiccated eggs in regard to spoilage. A. SCHMID. *Mitt. Lebensm. Hyg.* 16, 137-43(1925).—Egg powders that have a degree of acidity (detd. according to Kottsdorfer) of over 40 are considered to be unfit for consumption. S. discusses the possibility of the breaking down of the proteins, which also would tend to increase the acidity, besides free fatty acids from the ether ext. Danger of toxicity through bacterial action need not be feared so much, as the moisture content is usually rather low, being 4-6% and at the most 8%. S. recommends, besides detn. of the total fat and albumin, a detn. of sol. albumin. A modification of the Kottsdorfer method by Sudendorf and Penndorf is given. A high acidity is the first and most important indication of decompn., and should not be allowed in products to be sold.

J. C. J.

Yeast contamination as a source of explosion in chocolate-coated candies. D. B. SCHUTT. *Sci. Agr.* 6, 118-9(1925).—Bursting of chocolates was caused by the growth of yeasts, the source of which was a wooden barrel used to hold the excess filler until required for dipping. The trouble was controlled by installing vessels capable of being sterilized between the batches.

L. W. RIGGS

The method of Auerbach and Bodlander for the differentiation between honey and artificial honey. WILHELM MÜLLER. *Mitt. Lebensm. Hyg.* 16, 198-200(1925).—The ratio between the fructose and glucose is of such a variable nature, that it cannot serve as a criterion for the differentiation between real and artificial honey, as A. and B. claim. Results of analysis of 50 samples of honey are tabulated and given.

J. C. J.

Use of olive oil cake in horse rations. R. DUVAUCHELLE. *Bull. mat. grasses* No 4, 101-4(1925).—A 20-days' test with 1 horse and 2 mules indicated that 1 kg. of oats can be replaced by 1.2 kg. of a mixt. of equal vols. of olive oil press cake and of bran. The animals do not take the fresh cake, either alone or in admixt. with grain, and it should be air dried for 48 hrs. and then broken up to pass through a square-meshed sieve (2 meshes per cm.). The cake used contained H_2O 13, crude fiber 22.1, crude protein 6.9, ash 6.3, fat 8, N-free ext. 43.7%. It should be mixed with a substance rich in protein to compensate for the decrease in the latter when changing from grain to oil cake.

A. PAPINEAU-COUTURE

Filter for milk (U. S. pat. 1,568,001) 1.

COX, HENRY EDWARD: **Chemical Analysis of Foods.** Philadelphia: P. Blakiston's Son & Co. 323 pp. \$5.

Food product formed from fresh kola extract and lactose. A. CHALAS and E. CHALAS (NÉE BUTLER). *Brit.* 233,695, May 7, 1924. After the destruction of the oxides by heat or otherwise, kola ext. (preferably a soft hydroalcoholic ext.) is treated with boiling H_2O and powd. lactose is added and the mixt. stirred. It may be dried and formed into granules or tablets for use in aq. beverages such as coffee or tea or in broths.

Food from compressed and desiccated water hyacinth plants. J. H. LEFRWICE. U. S. 1,568,339, Jan. 5. A food which is suitable for cattle is prepd. by expressing

portion of the H_2O from water hyacinth plants, further reducing the moisture content sufficiently to avoid decompn., and comminuting the desiccated product.

Toasted flake "breakfast food." G. F. HUMPHREY. U. S. 1,568,162, Jan. 5. Pulp of apples or other fruit pulp is mixed with sugar, yeast and a cereal such as wheat flour, baked, subdivided and flaked and toasted.

Preventing discoloration of canned goods. T. W. MORGAN and W. W. MURRAY. U. S. 1,567,163, Dec. 29. The inner surface of a container for foods which may be formed of Sn plate is provided with a coating of lacquer contg. an insol. compd. of Zn or Cd or other insol. compd. or compds. of a metal forming sulfides which are not dark colored.

Vitaminized margarin. SMOERFABRIKKEN FLORA, A.-S. Norw. 41,688, July 27, 1925. Cod-liver oil to be added to margarine is first treated to cover the unpleasant taste, for instance, by emulsification and application of aromatic substances.

Apparatus for aerating, pasteurizing and cooling milk and cream. J. M. W. KITCHEN. U. S. 1,567,274, Dec. 29.

Apparatus for manufacturing sweetened, condensed milk. BROEDRENE GRAM. Danish 34,851, Aug. 10, 1925. The evaporator and the condenser work continuously in a closed system with complete exclusion of air. The app. is provided with an automatic shaking device.

Vacuum evaporator for milk and similar materials. N. J. NIELSEN. Danish 34,923, Aug. 17, 1925. Mech. features.

Pasteurizing apparatus. SILKEBORG MASKINFABRIK, ZEUTHEN & LARSEN. Danish 34,563 and 34,578, June 2, 1925. Mech. features.

Slow-pasteurizing apparatus. BROEDRENE GRAM. Danish 34,798, July 27, 1925.

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

Colloid chemistry of technical froths or foams. W. CLAYTON. *Ind. Chemist* 1, 489-91(1925).—Following an exposition of the general principles of frothing, C. discusses briefly (1) technical foams (milk froth, whipped cream, beer and beverages and firefoam), (2) froth and evapn., (3) priming of boilers (C. appears to employ "priming" and "foaming" synonymously), (4) flotation. E. G. R. ARDAGH

Advances in steam technology, especially very high-pressure steam and its industrial use. JOSSE. *Centr. Zuckerind.* 33, 1355-41(1925).—A lecture. Discussion. *Ibid* 1365-9, 1423, 1450. W. I. BADGER

Recovery and use of waste products. I. J. B. C. KERSHAW. *Ind. Chemist* 1, 434-7(1925).—Attention is drawn to the following losses in industry and their prevention or mitigation: waste fuel and waste heat: chimney losses, radiation and convection losses, unburned fuel, heat losses in elec. power generation, heat losses with exhaust steam. II. The chemical industries. *Ibid* 492-4.—Materials wasted are: arsenical wastes, Se, Tl, Ca compds., liquid chem. wastes and waste gases. 9 illustrations. E. G. R. ARDAGH

Layout and design of chemical plants on a philosophical basis. CROSBY FIELD. *Chem. Met. Eng.* 32, 794-9(1925).—"There is a philosophy underlying the growth of each industrial plant. The specific application of this philosophy to the problem in hand should result in an 'ideal' general plan.* * * *The ideal general plan can best be outlined by first making a schematic diagram showing the relation of all storage and mfg. operations and the materials concerned therewith and then clothing this diagram. This schematic diagram* * * *is similar to the kinematic diagram underlying the general plan of a machine. These assertions have been illustrated by application to a number of different plants, from a simple one to a very complex one." W. C. E.

Carbon dioxide as an index of fatigue. W. N. POLAKOP. *Mech. Eng.* 47, 1043-6(1925).—Earlier workers have shown that net CO_2 exhalation increases with the increase of pulmonary ventilation that follows exertion. P. detd. per cent CO_2 in the exhaled air of two firemen working under closely observed conditions. CO_2 was detd. by alkali absorption every 30 min. in a simple, portable app. Max. CO_2 in exhalation is an index of full load on the muscles; decrease of CO_2 content in spite of continued work indicates overload and is a signal of fatigue; age and size of the worker influence CO_2 content; peaks in CO_2 curve follow exertions; training of workers considerably reduces CO_2 exhalation for the same release of productive work. C. M. SALLS

Gas hazards in street manholes. S. H. KATZ, E. G. MEYER AND J. J. BLOOMFIELD. *Bur. Mines, Repts. of Investigations* No. 2710, 22 pp.(1925).—The atm. in 15 manholes in Pittsburgh and 23 in Phila. were analyzed by means of the Haldane app.

(0.03% CO minimum), hoolamite indicator (0.07% CO minimum), and PdCl_2 test papers (0.25% CO minimum). The carbon in the hoolamite indicator should be renewed after about 100 tests. CO is the principal gas found in manholes, although others also were found. Explosive mixts. were found in 3 holes. App. for testing for explosive gases in manholes is described. Out of 23 samples, 8 had more than 0.1% CO, and one had 4.7% CO. Preventive measures include the hosemask, self-contained oxygen breathing app., universal gas mask, lifeline and a knowledge of the modified Schaeffer prone pressure method of artificial respiration. Ventilation by means of a hand-operated rotary blower, similar to a forge blower, with a 4-inch canvas pipe delivering air at the bottom of the hole is recommended. C. M. SALLS

Calcium and tuberculosis—a thesis in hygiene comprehending the influence of an inspired dust on a specific infection of the lungs. MIRIAM S. ISZARD. *J. Ind. Hyg.* 7, 505–30 (1925).—Physiol. expts. on 54 rabbits show that $\text{Ca}(\text{OH})_2$ dust is not harmful, in fact it is probably beneficial in aiding the removal of silica particles. Tuberculous development was retarded slightly but not prevented by inhaling $\text{Ca}(\text{OH})_2$ dust 6 hrs. daily in concn. of 25 mg. per 100 cu ft. The industrial hygiene of gypsum, cement, marble, granite, clay, coal, limestone, iron oxide, emery, glass, sandstone, flint and cyanamide is reviewed. C. M. SALLS

Silicosis among miners. R. R. SAYERS. *Bur. Mines, Tech. Paper* 372, 24 pp.; *Chem. News* 131, 353–4 (1925)—Silicosis is a lung disease due to breathing very fine rock dust. Rock dust high in free silica is most injurious. Silica dust is somewhat sol. in water and in weakly alk. liquids similar to body fluids. It is thought that silica dust by its sharp-edged and needlelike particles injures the lung tissue mechanically, or that, being sol. in water and weakly alk. liquids, it injures lung tissue by its poisonous action. For detg. the amount of dust in the air the sugar-tube method, the konimeter (Kotze and Australian modification), and the impinger are chiefly used in the mining industry in the United States. Photographs of each app. are shown. The elimination of silicosis depends on preventing the formation of dust by wet mining methods, the use of sprays and water blasts to lay the dust after blasting, good mechanical ventilation, and physical examm. of all miners. C. M. SALLS

Treatment of burns caused by acid or alkali. W. H. HINKEL. *Nation's Health* 7, 828–30 (1925)—First remove the acid or alkali by copious application of water, warm if possible. When the last trace of superficial acid has been washed away, apply mild neutralizing substances, ointments, etc. The medical treatment of severe burns is discussed. Acid fumes affect the lungs, not the blood. Valves encased in lead boxes, regular inspection of tanks, properly constructed and maintained fume lines, adequate ventilation, working companions, and showers are recommended. C. M. SALLS

Efficiency of the oxygen-carbon dioxide treatment of carbon monoxide poisoning. C. K. DRINKER. *Am. Gas. Assoc. Monthly* 7, 761–74 (1925); *J. Ind. Hyg.* 7, 539–58 (1925); 8, 50 (1926).—Conclusions concerning the 5% CO_2 -95% O_2 treatment are: (a) The inhalation treatment is exceedingly valuable in mild gassing, relieving or preventing the occurrence of headache, nausea, etc.; (b) in serious cases, the patient revives rapidly and thoroughly; (c) it is practicable to use the inhalation treatment with prone pressure artificial respiration when breathing has ceased. C. M. SALLS

Gas mask for protection in air against all gases, vapors and smokes. A. C. FIELDNER, S. H. KATZ, H. W. FREVERT AND E. G. MEITER. *Bur. Mines, Repts. of Investigations* No. 2719, 10 pp. (1925).—The type "N" or all-service mask is designed for protection in air against all gases, vapors and smokes. The physical and chemical tests conducted upon it, the protective principles involved, the construction of the essential elements of the canister and attachments, and the uses and limitations of the mask are discussed. Poisonous materials are eliminated as follows: (1) acid gases by chem. combination with caustite, a NaOH prepn.; (2) org. vapors by adsorption in activated charcoal, either plain or impregnated with CuSO_4 ; (3) NH_3 by adsorption in the charcoal and chem. combination with CuSO_4 ; (4) smokes, dusts and mists by filtering action of cotton wool; (5) CO by oxidation with O of air through catalytic effect of hopcalite, a CuO-MnO_2 mixt.; (6) H_2O vapor by fused CaCl_2 . A timer, moved by the impulses of the air stream during inhalation, makes one revolution in 2 hrs. of normal breathing, and indicates that a new canister should be attached. Methods and results of (a) chem., and (b) actual service tests are reported, and the use of the mask is approved for "respiratory protection in mine atmospheres where flame safety lamps are burning, and * * * above ground in air that contains acid vapors, organic vapors, or carbon monoxide not exceeding 2% by vol., ammonia not exceeding 3%, and in smokes, dusts and mists; or not exceeding 2% of total poisonous gases when more than one gas is present."

W. C. EBAUGH

The physical and chemical basis of industrial aspirators. H. ENGELHARD. *Z. Elektrochem.* 31, 590-3(1925).—The harmful particles to be filtered from the inhaled air must reach the wall of the filtering medium during the $\frac{1}{10}$ -1 sec. that they remain in the filter, and must be mechanically or physically held or changed to a harmless substance. The necessary thickness of the filter may be detd. by calcg. the Brownian movement of the particles. Colloidal dusts give special difficulty which is somewhat overcome by the use of several filters. Mists require greater filter surface than smokes. Highly adsorptive charcoal is most efficient for removing noxious gases. If out of concn. C_a the adsorption layer removes dC_1 of undesirable element, the filter will be satisfactory if $C_a - dC_1 - dC_2 \dots$ falls below the lowest analytical trace of that element, usually about $1 \times 10^{-6}\%$ by vol.

High-voltage insulation. J. B. WHITEHEAD. *Elec. World* 87, 31(1926).—Review of progress during 1925. ROSALIE M. COBB
C. G. F.

Calculation of the contents of partly filled horizontal cylinders (HACK) 1. Acetylation of organic substances (U. S. pat. 1,567,785) 10.

AUB, JOSEPH C., MINOT, A. S., FAIRHALL, LAWRENCE T. AND REZNIKOFF, PAUL: **Lead Poisoning.** Baltimore: The Williams & Wilkins Co. \$4.

WEYMAN, G.: **The Design and Arrangement of Chemical Plant in Relation to Its Economic Control.** London: E. Benn, Ltd. 140 pp. 6s. Reviewed in *Ind. Chemist* 1, 502(1925).

Rectifying system for separating constituents of gaseous mixtures. G. I. E. PLATAT. *Brit.* 232,986, April 26, 1924. Rectifying columns for sepn. of constituents of hydrogenated coal gas or other gaseous mixts. contg. H, hydrocarbons, etc., are combined with a rectifying column in which liquid N is obtained from air on the upper plates by a condenser. The liquid N is employed as rectifying liquid for the mixts. under treatment. Numerous details of procedure are described.

Destructive distillation. C. E. RIEMER. *Swed.* 59,073, July 15, 1925. Solid or liquid org. substances are heated directly by means of circulating indifferent gases, preferably under pressure, in exchangeable gas-tight retorts resting on cars transportable on rails, the retorts being coupled exchangeably in parallel or in succession in a system of pipe-channels between a common heating app., for instance, a recuperator, and a common condenser connected with the heating channels of the recuperator through a scrubber and a fan.

Ammonia absorption apparatus for use in refrigeration. C. SENSSENBRENNER. U. S. 1,568,476, Jan. 5. An app. is described which is adapted to serve alternately as a generator and as an absorber.

Electric insulating material. A. I. LABBE. U. S. 1,567,277, Dec. 29. Slaked lime (substantially free from magnesia) 40 is mixed with port. cement 50 and sand 10 parts and molded to form insulators for resisting high voltages.

Heat-insulation. F. L. PILLIOD. U. S. 1,568,415, Jan. 5. A felted mass or sheet of long fibers of amosite interspersed with about an equal weight of short fibers of asbestos is impregnated with Na silicate.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

The rate of deoxygenation of polluted waters. E. J. THERIAULT. *Proc. Am. Soc. Civil Eng.* 51, 1819-28(1925).—Samples of Ohio-River water were incubated at 9°, 20° and 30° and the rate of deoxygenation was observed. The rate is very uniform during the first nine or ten days, a marked acceleration occurring after sixteen days. The first stage is due to oxidation of carbonaceous matter; the second marks the beginning of nitrification. The results conform well with Phelps formula: $x = L(1 - 10^{-Kt})$, in which x = oxygen absorbed in t days; L = total oxygen absorbed in the first stage; K = a const. The oxidation of nitrogenous matter is probably complete at 40-50 days. Continued absorption is due to oxidation of cellulose-like material. The different stages of deoxygenation make necessary a knowledge of the history of the sample in the proper interpretation of lab. results. From the 5-day oxygen-demand values, the av. *per capita* oxygen requirement in several cities considered is about 51.1 g. per day. B. H. P.

Bacterial pollution and natural purification in the Ohio and Illinois rivers. J. K.

HOSKINS. *Proc. Am. Soc. Civil Eng.* 51, 1843-55(1925).—The quantity unit for expressing bacterial concn. is defined as the product of the discharge of 1 cu. ft. per sec. and a concn. of 1000 bacteria per cc. The no. of units of a given stream then equals the product of discharge in sec. ft. and bacteria per cc. divided by 1000. Tables and graphs show bacterial pollution in quantity units per capita for Cincinnati, Louisville, Peoria and Chicago. Seasonal changes vary from 25% of the yearly total in Jan. to 225% in June. Bacterial concn. can be computed from population \times quantity units per capita \div by thousands of sec. ft. Tables of computed and observed values for the 4 cities show good agreement. Bacterial decrease in relation to time of flow is fairly regular; it is affected by temp., original concn. and other factors. Tables are given. B. H. P.

A review of the work of the United States Public Health Service in investigations of stream pollution. W. H. FROST. *Proc. Am. Soc. Civil Eng.* 51, 1810-7(1925); *U S Pub. Health Repts.* 41, 75-85 (1926). BEN H. PETERSON

The trend of purification plant design and operation. WELLINGTON DONALDSON. *Engr. & Contr.* 64, 371-76(1924).—The tendency has been toward greater flexibility of operation and adequate metering of water flows, master venturi meters being usually provided either at the input or output. Aeration for removal of odors and iron is being used by an increasing number of plants. Preliminary sedimentation before the application of the coagulant has proved advantageous for plants handling very muddy waters. There is no remarkable improvement in coagulation basin design but there have been improvements in cleaning arrangements. Dry-feeding devices are gaining popularity. Perforated pipe is leading in popularity for rapid sand filter under-drains. The use of air wash in addition to water wash is almost obsolete. There is great diversity in design of auxiliary filter equipment. Practically all sterilization is now done with liquid chlorine. C. C. RUCHHOFF

Modern British practice in water softening. IV. Lime cream and soda ash plants (Kennicott, Lassen-Hjort, Paterson and Porter). D. BROWNLIE. *Ind. Chemist* 1, 495-500(1925); cf. *C. A.* 19, 3553. E. G. R. ARDAGH

The use of zeolites to soften water by filtration. H. W. TERRY. *Paper* 62, 766-8(1925).—Tables and charts are given which can be used to calc. the filter diam. and the depth of zeolite required to soften a given vol. of water of known hardness. D. B. DILL

The use of lime for treating public water supplies to prevent corrosion and "red water." J. R. BAYLIS. *Rock Products* 28, No. 18, 59-60(1925). R. WILSON

Lime treatment of water for the manufacture of raw water ice. A. S. BEHRMAN. *Rock Products* 28, No. 18, 57-8(1925). RAYMOND WILSON

A sensitive biological indicator for the chemical condition of inland water. AUGUST THIENEMANN. *Naturwissenschaften* 13, 868-9(1925).—It has been observed that the very common waterflea, *Gammarus pulex*, only lives in those waters that have a relatively high O content, combined with a rapid O replenishment; it is sensitive to all inorg. pollution and to decaying org. material. Even more sensitive test objects for the quality of water are the epizoic protozoa, *Spirochona gemmipara* and *Dendrocomeles paradoxus*, occurring on the "Kiemenblättchen" of *Gammarus*. They are relatively resistant to temp. changes but do not appear when appreciable NaCl, acids or org. pollution is present, even when the flea itself is unharmed. B. J. C. VAN DER HOEVEN

Difficulties encountered in purifying small quantities of boiler feed water. G. PARIS. *Chimie et industrie Special No.*, 143(Sept., 1925).—The $\text{CaO-Na}_2\text{CO}_3$ process can hardly give good results with a flow of less than 5 tons an hr. Processes using the addn. of a dissolved reagent can give good results with flows down to 600 l. an hr. Zeolite processes give good results with flows of less than 500 l. per hr. A. P.-C.

Sewage experimental work investigations. WILLEM RUDOLFS. *Can. Eng.* 49, 103-5(1925).—The results obtained when a reconstructed Imhoff tank was seeded with sludge and put into operation are compared with the operating results of an old tank. Although it took only 4 weeks for the bacterial population in the liquor of the new tank to become as great as in the old tank the results did not come up to expectations. The reason for this seemed to be that the relation between the incoming sewage and the ripe sludge was incorrect. Bacteria increase when a tank is operating and decrease when it is resting. The bacterial activities vary with the seasonal temp. but this effect may be overbalanced by the manipulation of the tank. The results of an expt. on fresh solids digestion in a stoppered bottle are given and discussed. C. C. R.

Buchner system for the disposal of household sewage. K. BUCHNER. *Gesundh. Ing.* 48, 618-9(1925).—A description with illustrations of a small disposal tank for household sewage. The settling compartment is of 250 l. capacity and is divided into 2 compartments. The septic chamber is of 500 l. capacity, circular in shape, with a

sloping bottom. Sludge is removed by a pipe leading to the center of the chamber. This chamber is to be emptied 3 times a year, when filled at a rate of 50 l. per week. With sludge estd. at 0.15 l. per person per day, this tank is designed for approx. 30 persons, and costs 800-1600 marks.

MARTIN E. FLENTJE

Sewage-disposal problems in Kansas. ERNEST BOYCE. *Munic. County Engr.* 69, 41-4(1925).—A general discussion.

C. C. R.

The glass-covered sludge-drying bed. W. S. COULTER. *Munic. County Engr.* 69, 57-60(1925).—The hotbed and greenhouse types of covered sludge-drying beds are described. Partition walls so that fresh sludge may be sepd. from partly dried sludge, proper ventilation and protection of the glass with wire screen for small plants are discussed.

C. C. R.

The rate of atmospheric reaeration of sewage polluted streams. H. W. STREETER. *Proc. Am. Soc. Civil Eng.* 51, 1829-42(1925).—The principal source of reaeration is absorption from the atm. In the Ohio-River studies this was found to follow the law, (1) $\log(D/D_0) = -K_2t$; in which D_0 is the initial oxygen deficit, D is deficit at time t and K_2 is a const. of reaeration which is governed by $K_2 - cV^n \times H^{-2}$, in which v is velocity, H is depth and c and n are consts. The rate is accelerated at higher temps. Reaeration is measured by combining this expression with the deoxygenation equation, (2) $\log(L/L_0) = -K_1T$, in which L_0 is oxygen absorbed in the first stage, L the oxygen requirement for time T and K_1 is the coeff. of deoxygenation, giving (3) $D = (K_1L_0/K_2 - K_1)(10^{-K_1t} - 10^{-K_2t}) + D_0 \times 10^{-K_2t}$. In the curves of equations (2) and (3) the difference at time t is a measure of the reaeration. Data are given and curves shown for calcd. and observed results.

BEN H. PETERSON

Recovery of gas in sewage disposal. SIERP. *Gas u. Wasserfach* 68, 773-6(1925).—The settling and decompn. tanks are covered so as to permit the collection of the gas evolved during the decompn. of the sewage. At an av. temp. of 12.5° the gas production is 3 cu.m./year/individual (in the sewage collection area), the compn. of the gas being CO₂ 15-20%, CH₄ 75-85%, N₂ 0-5%, this being an av. for a series of decompn. chambers. Photographs and diagrams of plants are given.

WM. B. PLUMMER

Feed-water deaeration increases plant economy. J. R. McDERMET. *Power Plant Eng.* 29, 1268(1925).—Deaeration reduces corrosion, making possible the use of economizers and extra high boilers, and the protection of turbines.

K. C. BEESON

The "Firstbrunnen," a new modification of the Imhoff tank. F. SCHIMRIGK. *Gesundh. Ing.* 48, 261-3(1925).—A modified Imhoff tank with ridged, radial settling troughs is described. This type of tank takes up less space and gives better results. Numerous drawings and illustrations are given.

J. J. SKINNER

Clay as soil colloids. A. F. JOSEPH. *Soil Science* 20, 89-94(1925).—By repeated extn. of the colloidal material from clay by means of a supercentrifuge practically the whole of the clay fraction can be obtained in colloidal condition. Several clays were investigated in this manner. A close correlation was found between the chem. compn. of clays and certain of their phys. and chem. properties. In general the higher the mol. ratio of SiO_2 to Al_2O_3 the more intense are all colloidal properties. R. B.

The chief factors which influence the heat of wetting of soil colloids. G. J. BOUYOUCOS. *Soil Science* 19, 477-82(1925).—Soil colloids lose their capacity to evolve heat on wetting after strong ignition. By grinding the ignited residue B. claims to have increased the sp. surface to approx. the original value and concludes that the heat of wetting is due to the phys. condition of the surface rather than the extent of surface. The active surface is referred to as hydrated, rough, porous and felt-like, the inactive as smooth and vitrified. Chem. compn. has an appreciable effect, especially the SiO_2 :- Al_2O_3 + Fe_2O_3 ratio. The higher the ratio in general the greater the heat of wetting. The heat of wetting is considered due to the change of the H_2O from a liquid to a semi-solid state; this is due to the strong attractive power of the solid phase; this force is considered both chem. and physical. R. BRADFELD

Heat of wetting of soils dried at different temperatures and the force at which soils absorb water. G. J. BOUYOUCOS. *Soil Science* 20, 67-72(1925); cf. *C. A.* 19, 2097.—Drying soils at 50° , 75° and 140° for 24 hrs. caused the heat of wetting to increase rapidly up to 107° and became practically const. above this point. Soils dried at 107° gave heat of wetting values from 293.7 to 1004.0% greater than the same soils dried only to 50° . The amt. of H_2O causing the heat of wetting is small, 1.40-12.10% and of this total the small fraction driven off last at 107° is responsible for the major portion. The expulsion of 0.719% H_2O at 107° raised the temp. of 125 g. of H_2O in 100 g. of soil over 3.28° which is 50% above that at the drying temp. of 75° . If heat of wetting is due merely to the compression of the H_2O the soils must exert an adsorption force equiv. to 156,200 atm. in the case of a muck. RICHARD BRADFELD

Some moisture relations of soils. M. M. MCCOOL AND A. W. WEIDEMANN. *Soil Science* 20, 243-7(1925).—When 5 g. of dry muck soils were treated with 60 cc. *N* KCl soln., filtered and the K content in an aliquot of the filtrate was detd. it was found to be higher than the original soln. This "negative absorption" of K was considered due to the fact that H_2O was absorbed more rapidly than KCl from the solns. used. In a second series of expts. sucrose solns. were used with even more striking results. With org. soils dried at room temp., 55° and 100° the amt. of H_2O absorbed varied from 16.9 to 20.29%, 23.64 to 29.95% and 26.10 to 35.84%, resp. The amt. of H_2O removed from sucrose solns. by various horizons of mineral soils varied from 1.9 to 6.5%, extd. colloids from 2.3 to 15.8% and fuller's earth 12.4%. R. B.

Colloidal behavior of soils and soil fertility. I. Suction force of soils as an index of their colloid content. J. S. JOFFE AND H. C. MCLEAN. *Soil Science* 20, 169-75 (1925).—The "suction force of soils" is estd. by imbedding a porcelain filter filled with H_2O in the soil and measuring the rise of Hg in a manometer attached to the top of the filter. Quartz sand gave a vacuum of only 1.2 cm.; loam soils ranged from 10 to 32 cm. while one clay gave a value of 40 cm. The effect of fertilizer treatments can be measured by this method. Lime depresses the suction force. It is claimed that this method may be used for estg. the colloid content of soils. R. BRADFELD

The influence of several factors on the reaction of the soil. F. W. BOBKO AND D. W. DRUSCHININ. *Z. Pflanzenernähr. Düngung* 5A, 345-69(1925).—The proportion of soil to water influenced the H-ion concn. of soil suspensions very slightly. The H-ion concn. of unlimed soils decreased slightly with increase in the amt. of water; while limed soils gave opposite results. With limed soils the p_{H} in the soil solns. was higher than in the water exts.; with unlimed soils the p_{H} was lower in the solns. than in the water exts. The higher the alky. (by titration) of soil exts., the higher the p_{H} . The H-ion concn. of a no. of fractions of leaching taken one after the other was about const. The H-ion concn. calcd. from the amt. of free CO_2 and HCO_3^- in the exts. or, after removal of the free CO_2 , from the HCO_3^- and CO_3^{--} agreed with the observed results. The p_{H} of all unlimed soils, humus soils and torf disagreed with results calcd. from such analyses and formulas. In exts. of humus-contg. soils the divergence was correlated with increased humus content of these exts. Conclusion: In such soils there are present acids with a larger dissociation const. than CO_2 , i. e., org. acids. R. M. BARNETTE

Plant growth on acid soils. HANNIS KIRSTE. *Z. Pflanzenernähr. Düngung* **5A**, 129-94(1925).—On the basis of the theories of Kappan and his school relative to the nature of soil acidity, the author made numerous expts. to ascertain the effect of "hydrolytic" and "exchange" acidity on the growth of different plants. He suggests dividing the plants into 2 groups according to their sensitivity to "exchange" acidity. Barley, turnip, luzerne, red clover, mustard, garden bean, wheat and peas are classed as sensitive to "exchange" acidity, while oats, serradella, corn, potatoes and lupine are classed as resistant to "exchange" acidity. Numerous ramifications of the relationship of the "exchange" acidity to plant growth, and the correction of this condition with CaCO_3 are given.

R. M. BARNETTE

The aluminium content of the soil solution and its relation to soil reaction and plant growth. O. C. MAGISTAD. *Soil Science* **20**, 181-225(1925).—An extensive investigation of the relation of acidity to plant growth both with and without sol. Al. The solubilities of Al in H_2O , nutrient soln., and soil solns. at varying p_{H} values were detd. To avoid copptn. of Ca as $\text{Ca}_3(\text{PO}_4)_2$ the Al was sepd. as AlPO_4 at p_{H} 5. Al was practically insol. between p_{H} 4.7 and 8. The curves for Al soly. in nutrient solns. and in soils when superimposed upon the Al- p_{H} soly. curve practically coincided at all points. Hence it is possible to predict the Al content of a soil soln. if its p_{H} value is known by referring to the soly. curve. At acidities greater than p_{H} 5 all crops except alfalfa suffered both H^+ ion and Al toxicity. Alfalfa died at these acidities whether Al was present or not. At acidities slightly above p_{H} 5 alfalfa, red clover, rye and oats suffered little or no Al toxicity. While corn, barley, and soy beans suffered appreciably. Since most natural soils fall within the range p_{H} 5-7, the beneficial effects of CaCO_3 for clover, alfalfa, oats and rye result from a decrease in acidity and not a decrease in sol. Al. With corn and barley over the same range acidity both factors are operative while with soy beans the Al seems to play the predominating role. Strongly alk. soils contain appreciable amts. of sol. Al which may be a factor in the toxicity. The addn. of Al increased the Al content of the crop and tended in some cases to decrease the Fe content. An extensive bibliography is appended.

A modified respiration apparatus for plant and soil studies.

R. BRADFIELD

Soil Science **19**, 411-5(1925).—The app. consists of two bell jars of the same kind of glass, 8 in. in diam. and 14 in. deep, connected edge to edge by a heavy rubber band. The lower jar is filled with soil to a depth of 8 in. and placed in a pot partially filled with sand, which serves as a convenient support. The upper jar is fitted with a No. 9 stopper with one glass tube leading to an air pump and the other to the CO_2 -absorbing reagents. The rubber band connection is superior to the usual wax seal because it is not affected by temp. changes. No trouble was experienced in recovering NH_3 introduced in the app.

R. BRADFIELD

Investigation of soil unproductivity (Verhagerung). F. KNICKMANN and M. HELBIG. *Z. Pflanzenernähr. Düngung* **5A**, 209-48(1925).—"Hager-humus" and "hager-soils" are described as occurring on the south and west sides of mountains, being due to the intensive action of sun and wind. A comparison of this soil, difficult of reclamation, with a normal soil of about the same relative position but lying on the north, as to phys. and chem. properties, was made. Both soils were derived from the same gneiss. The "hager-soil" was richer in humus, and had a higher water capacity. Analyses showed a like distribution of the particles in both surface and subsoil. The "hager-soil," while the normal soil showed an increase in the finer fractions (U. face of the soil. From analyses of HCl exts., K. and H. conclude that there was a strong increase in the "hager" profile and that the "hager-soil" might be likened to an "arid" soil while the normal soil was a "humid" soil. The larger amt. of alkali, together with the location of the "hager-soil," indicated a more intensive action of the sun (i. e., increased evapn.). The "hager-humus" of this abnormal soil was less sol. in HCl, indicating a lesser degree of decompn., while its higher soly. in NH_4Cl indicated a higher colloid soly. N in the "hager-humus" was less than in the normal. The correlation between mol. proportions and reaction (as shown by Ganssen) does not hold for these humus-contg. soils, while the proportions of lime to humus showed a correlation with the reaction of the soils.

R. M. BARNETTE

A comparative investigation of the determination of the phosphoric acid requirement of the soil. M. J. VAN DER SPIJ. *Z. Pflanzenernähr. Düngung* **5A**, 249-54(1925).—From comparative vegetation and chem. studies of 15 soils, the $\frac{1}{2}\%$ acid method was found preferable to other methods for the detn. of the requirement of a soil for P_2O_5 .

R. M. BARNETTE

The lime requirement of the soil. IV. The practical application of soil re-

studies. O. ARRHENIUS. *Z. Pflanzenernähr. Düngung* **5A**, 195-9(1925); cf. *C. A.* **19**, 3139.—The value of a systematic study of the reaction (H-ion concn. of soil suspensions) of soils and methods for mapping such results together with the application of the data for the culture of plants best suited to a given reaction are given. General rules for the alteration of the reaction of different soil types with marl are indicated. R. M. B.

The influence of liming, temperature, and compaction on the movement of soluble salts in soils. I. C. WHETING. *Soil Science* **19**, 459-66(1925); cf. *C. A.* **19**, 2098.—Dry soil (100 g.) + 2 g. of the finely powdered salt were thoroughly mixed, placed in a small glass tube 20×35 cm. and brought to optimum H_2O content. The tube was filled with the same soil at the same H_2O content but without added salt. Both ends of the tube were sealed with paraffin and the movement of salt was detd. at intervals by the f.-p. method. When $0.01 N Ca(OH)_2$ was used to moisten the soil instead of H_2O a more rapid distribution of KCl and $NaNO_3$ was noted. $CaH_4(PO_4)_2$ showed no movement. Salt movement was very slow near the f. p. but was rapid at 65° . Degree of compaction had no appreciable influence upon the rate of salt movement at the H_2O content used. R. BRADFIELD

Easily soluble calcium of soils as an indicator of their response to liming. J. R. FLEETWOOD. *Soil Science* **19**, 441-58(1925).—None of the usual lab. lime requirement methods gives a satisfactory index of a soil's response to lime applications in the field. In this study soils with known response to liming were selected from expt. fields in Mo., Iowa, Ill., Ohio and Ky. and the amts. of Ca dissolved from a 1.2 g. oven-dry sample by 600 cc. $0.04 N H_2CO_3$ detd. p_H values and Truog acidity values also are given. A much closer correlation was found between sol. Ca and field response to liming than either p_H value or Truog acidity. In general the relation between fertility and lime response was fair; in the exceptional cases the sol. Ca content proved a better index. R. BRADFIELD

The absorption of phosphate by Pasteur-Chamberlain filters. F. W. PARKER. *Soil Science* **20**, 149-58(1925).—New Pasteur-Chamberlain filters when treated with cold H_2O yielded solns. contg. as much as 0.392 p. p. m. of phosphate, hot water extn. as much as 0.94 p. p. m. in the first portions of filtrate. This amt. is larger than that found in many soil exts. New filters did not absorb an appreciable amt. of P from dil. P solns. but filters which had been used for prep. soil exts. absorbed considerable, apparently because of the colloidal soil material retained in the filter. Washing the used filters with hot 1:1 HCl, and then igniting reduced but did not destroy the absorptive capacity of the filters for P. The coeruleo-molybdate method was used for the P detns. and proved satisfactory. R. BRADFIELD

Distribution of nitrogen in the podsol profile. G. EDGINGTON AND J. R. ADAMS. *Soil Science* **20**, 177-9(1925).—Five fairly typical podsol profiles from New Hampshire were examd. for N, acidity and moisture equiv. The dark brown A horizon being rich in org. matter was highest in N, 1.40-2.00%, and had the highest moisture equiv., 101-190; the leached A_2 horizon was gray in color, N varied from 0.051 to a 133% and moisture equiv. from 11.2 to 26.8%. The zone of accumulation B was brown in color, N 0.279-0.426, moisture equiv. 33-79% while the parent material, horizon C, was in most cases yellow-brown in color, N 0.055-0.219 and moisture equiv. 13.1-48.1%. Variations in p_H value were small but were in general lower in the A_2 horizon. R. BRADFIELD

Inoculating soil with Azotobacter. P. L. GAINEY. *Soil Science* **20**, 73-87(1925).—Small plot field studies on the effect of inoculation of 2 *Azotobacter*-free acid soils furnish further evidence that: (1) the introduction of *Azotobacter* into soils which normally do not contain them is without effect in establishing a permanent flora; (2) if the acidity is reduced to p_H values above 6 by the addn. of basic materials like $CaCO_3$ an *Azotobacter* flora can be established by inoculation; (3) if the acidity of such soils rises in time to p_H values lower than 6 the organisms will disappear; (4) the N-fixing ability as measured by culturing in a mannite medium of a soil normally devoid of *Azotobacter* can be markedly increased by inoculation with this organism. RICHARD BRADFIELD

The carbon dioxide content of the soil air as a factor in the absorption of inorganic elements by plants. F. W. PARKER. *Soil Science* **20**, 39-44(1925).—The CO_2 content of the soil air was maintained at 3 levels by (1) removal by aspiration, (2) untreated, (3) CO_2 added at the rate of 1 g. per jar per day. In the first expt. rape, oats and clover were grown in a poor Norfolk sandy loam soil which received NH_4NO_3 but no other fertilizer. Dry wt. of tops, ash, Ca and P were detd. The variation of the CO_2 content had no appreciable effect except with oats. The ash content of this crop was materially increased apparently because of an increased absorption of SiO_2 . In a second series cpts. cowpeas and sorghum were grown with and without applications of acid and phosphate, the CO_2 treatments remaining the same as in the first series. The

CO₂ content of the air had no appreciable influence in either case. Yields were increased by the P treatments, rock phosphate being equal to acid phosphate with sorghum. The availability of the former was not influenced noticeably by the CO₂ treatments.

RICHARD BRADFIELD

The availability of nitrogen in nitrate of soda, ammonium sulfate and dried blood when the amounts of phosphoric acid and potash are varied. A. W. BLAIR AND A. L. PRINCE. *Soil Science* 19, 467-76(1925).—A continuation of the work previously reported (*C. A.* 18, 2937) on the effect of varying K and P upon the availability of N applied as NaNO₃, (NH₄)₂SO₄ and dried blood. Doubling and tripling the standard amt. of P did not change the yield of rape and buckwheat while doubling the normal rate of K depressed the yield of rape. The N content of the crops was not appreciably affected by either the high P or K treatments. NaNO₃ gave the largest yields and the highest N recovery in the first crop (rape) while dried blood gave the largest yield with the residual crop of buckwheat.

R. BRADFIELD

Biochemical effects of gypsum on Iowa soils. W. B. BOLLEN. *Soil Science* 19, 417-40(1925).—Gypsum had practically no effect on the no. of soil organisms developing on agar plates, nitrification, sulfonation, or the lime requirement of the soil. S markedly increased the sulfofying power of the soil. Crop growth, especially alfalfa, was materially increased by both S and gypsum. The effect of the gypsum is believed to be due largely to SO₄ supplied. One soil having its *p_H* value reduced to 3.23 by S applications supported a heavy growth of *Penicillium luteum*, which has the power of oxidizing S. This highly acid soil had also the greatest nitrifying power of the series. Increased yields of alfalfa were obtained by gypsum applications. In nearly every case gypsum-treated plots seemed to stand the drought better than the checks.

R. B.

Effect of straw on accumulation of nitrates and crop growth. T. L. MARTIN. *Soil Science* 20, 159-64(1925).—In general wheat straw treatments caused a decline in the nitrate in the soil in 3 series of pot expts. The larger the application of straw the greater was the decline in soil nitrate for a 4 month period. Crop yields were depressed in proportion with nitrate. After the straw had been allowed to decompose for 12 months its depressive influence disappeared.

R. BRADFIELD

The effect of potash fertilization on the yield of our most economically important plants. R. LEONHARDS. *Kali* 19, 413-7(1925).—Statistics are given of German potash consumption, and the various available forms of potash are economically discussed from the standpoint of transportation. Increased returns (crop and monetary) from potash fertilization of beets, potatoes and corn, under various conditions, are shown by tabulations.

WM. B. PLUMMER

The estimation of "polysulfide" sulfur in spray materials. WM. GOODWIN AND H. MARTIN. *J. Agr. Sci.* 15, 96-105(1925).—The method of R. M. Chapin was critically examd. and, with slight modifications to increase rapidity and ease of manipulation, is recommended for routine work in the examn. of S spray materials. The modified method is carried out as follows: Add 25 cc. of the diluted spray material (1:25 for liquid and 1:50 for solids) to a mixt. of 10 cc. ammoniacal ZnCl₂ (50 g. ZnCl₂ dissolved in 500 cc. H₂O, with 125 cc. NH₄OH, sp. gr. 0.90 and 50 g. NH₄Cl, dil. to 1000 cc.) and 35 cc. cryst. Na₂SO₃ in a 300 cc. conical flask. The Na₂SO₃ must be freshly prepd. Place the flask on a steam bath at full heat for 45 min. and at 10, 20, 30 and 40 min. intervals shake well, washing down the sides of the flask with boiling H₂O. At 45 min. remove from the steam bath, add 30 cc. 10% crystd. SnCl₂, let stand 5 min. and filter into a 500 cc. flask, using a good grade of filter paper not larger than 12.5 cm. Wash well with hot H₂O, until at least 200 cc. have passed the filter, cool, make up to vol. To 50 cc. portions add 1 drop of methyl red (0.2% in 95% alc.) and 10% C₆H₅O₆ from a buret to slight acidity. Titrate with 0.05 N I, using starch as an indicator. Correct for thiosulfate S by the official A. O. A. C. methods, except C₆H₅O₆ is used in lieu of HCl. Working with the quantities herein specified, if *X* be the figure of the polysulfide titration and *Y* that of the thiosulfate titration, then *X*-(*Y*/5) gives the true polysulfide titration which if less than 35 (the no. of cc. of Na₂SO₃ used) indicates that an excess of Na₂SO₃ is present.

R. B. DEEMER

Calcium cyanide fumigation. S. N. GORÉ. *Indian J. Med. Research* 13, 287-99 (1925).—"The use of Ca(CN)₂ for the generation of HCN for fumigation purposes is much simpler and more convenient than a mixt. of H₂SO₄ and KCN or NaCN. The mere exposure of Ca(CN)₂ to the air results in the evolution of HCN in an hour and a half." Air-tight spaces are necessary. Under this condition 1 oz. Ca(CN)₂ per 100 cu. ft. provides a lethal concn. attained in 1½ hrs. and maintained for 4 hrs.

F. K.

The relative toxicity of the arsenates of calcium (to insects). S. B. HENDRICKS, A. M. BACOT AND H. C. YOUNG. *Ind. Eng. Chem.* 18, 50-1(1926).—The av. longevity

and the ratio of As_2O_5 in the body to that in the feces were satisfactory criteria of toxicity for arsenicals in the system $\text{CaO}-\text{As}_2\text{O}_5-\text{H}_2\text{O}$ when fed to grasshoppers (*Melanoplus femur-rubrum*). The toxicity of Ca arsenates decreases with increase in the mol. ratio $\text{CaO}:\text{As}_2\text{O}_5$ in combination, but is not greatly affected by $\text{Ca}(\text{OH})_2$ in the presence of $\text{Ca}_3(\text{AsO}_4)_2 \cdot \text{H}_2\text{O}$. The basic Ca arsenates have a const. toxicity for the cotton boll weevil (*Anthonomus grandis*) which is lower than that for the acid Ca arsenates.

CHAS. H. RICHARDSON

Leaf diseases of Hevea. I. C. H. WRIGHT. *India Rubber J.* 70, 1027-9, 1145-7 (1925).—Descriptive, including the current use of chemicals as combative agents. Several metallic salts other than CuSO_4 are highly toxic to fungi, and as a particularly effective fungicide it is suggested to use a mixt. contg. CuSO_4 2, $\text{Al}_2(\text{SO}_4)_3$ 2, NiSO_4 1, lime 5 lbs. in 50 gals. of H_2O . Other suggestions include a combination of $\text{Ca}_3(\text{AsO}_4)_2$ and lime-S mixts., NaF and CaF_2 . Methods of prepn. of the more effective solns. are described in detail.

C. C. DAVIS

A study of the methods of combating the "olive fly" (*Dacus oleae*) in Portugal. A. F. DE SEABRA. *Bull. mat. grasses* No. 4, 93-100 (1925).—An outline of the work recently organized for the control of the "olive fly." The work is not sufficiently far advanced to report any results

A. PAPINEAU-COUTURE

The fight against the "olive fly" (*Dacus oleae*) at Cenia (Spain). ANON. *Bol. mens. olivi cultura* No. 71, 476 (1924); *Bull. mat. grasses* No. 4, 100 (1925).—Spraying expts. with the usual molasses-Na arsenate mixt., with Bordeaux mixt. and with Na arsenate gave very promising results, only 0-0.3% of the fruit from the sprayed trees being attacked, while in neighboring olive groves 50-90% of the fruit were attacked according to the variety of olives. With 0.25% of arsenate some of the trees were slightly burned, but none was with 0.15%

GREAVES, JOSEPH E. and GREAVES, ETHELYN O.: **Bacteria in Relation to Soil Fertility.** New York: D. Van Nostrand Co. 239 pp. \$2.50. Reviewed in *Ind. Eng. Chem.* 18, 106 (1926).

Fertilizers. P. T. AXELSEN. U. S. 1,567,408, Dec. 29 Fertilizers in solid pulverulent condition are passed under pressure between smooth rotating surfaces to form them into thin, polished sheaves which may be stored without coalescing into lumps.

Fertilizer from calcium cyanamide. NORSK HYDRO-ELEKTRISK KVAELSTOF-AKTIESELSKAP. Norw. 41,802, Aug. 31, 1925 Com. CaCN_2 is treated with moist urea nitrate at a temp. between 50° and 80° ; by this procedure the CaCN_2 is converted into urea

Calcium cyanamide. STOCKHOLMS SUPERFOSFATFABRIKS A.-B. Swed. 59,148, July 29, 1925. The reaction between CaC_2 and N is carried out in a furnace having the shape of a rotating body with the least possible outside surface in proportion to the vol., for instance, an ellipsoid.

Insecticide and fungicide. H. P. BASSETT and M. R. ISAACS. U. S. 1,568,044, Jan. 5. A compn. adapted for spraying or dusting comprises Ca diarsenate 70, CaO 30 and casein 3 parts.

Fungicide and insecticide. O. F. HEDENBURG. U. S. 1,568,455, Jan. 5. Bordeaux mixt. and Pb arsenate are mixed with dextrin, casein and a sol. chromate to obtain a deflocculating and adhesive effect and produce a compn. adapted for use with H_2O as a spray.

Plant spray. C. F. DILLER. U. S. 1,568,445, Jan. 5. A compn. adapted for spraying on tobacco, roses or other plants comprises a suspension of dried plant bacterial enzyme and chromatin granule products, in H_2O , Bordeaux mixt. or other suitable liquid vehicle.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

The wines of Canton Wallis during 1923 and 1924. ANON. *Mitt. Lebensm. Hyg.* 16, 203-4 (1925).—The max., min. and av. results of analyses of a large number of white and red wines of the 1923 and 1924 vintages are tabulated.

J. C. J.

The detection of watering in wines. C. A. GRAU. *Rev. Facultad Ciencias* 3, No. 2, 133-42 (1925).—Ten % or less of water betrays itself only by the presence of

nitrate. For the detection a soln. of 0.002 g. diphenylamine in 100 cc. concd. H_2SO_4 is recommended. The com. yellowish product is more sensitive than the c. p. one.

MARY JACOBSEN

Sensitiveness of the taste towards sulfurous acid in wines. P. BALAVOINE. *Mitt. Lebensm. Hyg.* **16**, 133-6(1925).—A discussion of the use of SO_2 as gas or in liquid form in the wine industry. A short résumé of the literature on the subject is given, including max. amts. recommended by different authorities. B. has detd. the free and total SO_2 in different wines, including for each a description of the taste, and has given his results in tabulated form

J. C. JURRIENS

The determination of diastase in malt extracts. SEELIGMANN. *Chem.-Ztg.* **49**, 943(1925).—A substance has a diastatic power of 1000 Pollak units if 1 g. is able, in $1\frac{1}{2}$ hr., to produce at a temp. of 40° 1 g. maltose from a 3% arrowroot starch soln. The Pollak unit is detd. as follows: 20 g. malt ext. are made up to 200 g. with H_2O , the ext. is filtered and an aliquot is taken. The 3% arrowroot soln. is prepd. by suspending 7.5 g. in 250 cc. boiling H_2O and heating until the material gelatinizes, cooling to 40° and adding the malt ext., and shaking frequently during digestion. The diastatic action is stopped by adding 3 cc. of 10% NaOH and cooling to room temp. The vol. is then made to 300 cc. and the soln. is shaken and titrated with 25 cc. Fehling's soln., diluted with 25-50 cc. H_2O , while heating to boiling. The titration is completed when the supernatant fluid has a weak yellow color. The titer of Fehling's soln. is detd. by reducing pure maltose. If 25 cc. Fehling's soln. are equiv. to 185.5 mg. maltose and 25 cc. Fehling's soln. decolorized 31 cc. of the arrowroot soln., then 300 cc. arrowroot soln. with 0.4 g. malt ext. would yield 1793 mg. maltose, and 1 g. malt ext. would have converted 4482.5 mg. maltose. From this amt. the maltose already in the malt should be deducted and the remainder may be expressed in Pollak units.

C. N. FREY

Electrolytic treatment of beetroot molasses or fermentation residues (Brit. pat. 233,196) **28**.

"Vitamin malt preparation." O. STINER, A. HAUSWIRTH and A. GAMS. U. S. 1,568,196, Jan. 5. An amylaceous material such as chestnut meal is saccharified with ground fresh green malt and H_2O in the presence of citric acid, tartaric acid or other non-toxic "polybasic" org. acid, in sufficient quantity to make the reaction feebly acid to "congo," and at temps. below 60° .

Wort. AKTIEBOLAGET SEPARATOR. Brit. 233,321, May 5, 1924. Solid or slimy residues remaining after extn. of wort are treated with H_2O to produce a dild. wort from which the residues are sepd. centrifugally. This process may be repeated and the very dil. wort obtained may be used instead of H_2O in the first treatment.

Filtering vessel for yeast manufacture. SVENSKA JÄSTFABRIKS AKTIEBOLAGET. Swed. 58,961, June 25, 1925. Mech. features

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Researches on the root of *Gentiana lutea* L., which grows wild on the slopes of Gennargentu (Sardinia). R. BINAGHI AND P. FALQUI. *Ann. chim. applicata* **15**, 386-96(1925).—The botany has been fully described by Moris (*Flora Sarda* **3**, 71 (1858-9)). The active principle of the root was extd. by the method of Tanret (cf. *Thesis*, July 20, 1905) in modified form, since a survey of various methods pointed to this as the most systematic and complete. The root after being dried in air at room temp. and pulverized gave in %: H_2O 13.78, ash 6.21, EtOH ext. 52.00. The ash was straw-colored and the EtOH ext. (extd. at 60°) red-brown, the latter giving with H_2O a clear soln. with green opalescence. Fresh root was then pulverized, digested 5 times with 95% EtOH at room temp., the ext. evapd. *in vacuo*, the residue extd. with cold petr.-ether, and evapd., which left a yellow-red oily residue (I) weighing 3.4% of the root. The residue insol. in petr.-ether was extd. with cold H_2O , which left an amorphous yellow product (II) weighing 0.5% of the root. The red-brown aq. filtrate after concn. to a sirup was completely sol. in cold 95% EtOH. After evapn. *in vacuo* this was extd. with boiling EtOAc, which gave a red-brown soln. (III) and a yellow-brown residue (IV). I contained fats and cholesterol, II resins insol. in H_2O , III the greater part of the glucosides and IV the sugars. Sapon. of I with alc. KOH and extn. with Et $_2$ O after removal of EtOH and diln. with H_2O gave a wax which crystd. in silky needles from abs.

EtOH, m. 142–3°, insol. in H₂O and sol. in CHCl₃, CS₂, C₆H₆, petr.-ether, vegetable oils and glycerol, giving positive Liebermann-Burchard (cf. *Ber.* 18 (1875) and Sal-kowski (*Z. anal. Chem.* 11, 44) reactions, $[\alpha]_D^{20}$ –29.4° (in CHCl₃), the m. p. and rotation values approaching the gentiosterine of Tanret. **III** after evapn. *in vacuo* deposited a cryst. product (V), leaving a liquid insol. in EtOH (VI). Analysis and various reactions proved V to be gentiopierin, which was further confirmed by hydrolysis to be gentiogenine and glucose. Extn. of the mother-liquor of the gentiopierin, crystn. by abs. EtOH, pptn. as tannate in satd. MgSO₄ soln., the ppt. decompd. by Ca(OH)₂ and crystd. from boiling abs. EtOH gave gentimarine (cf. Tanret, *loc. cit.*) blackens FeCl₃ and reduces Fehling soln. From the EtOAc mother liquor gentine was also recovered (also discovered by Tanret), in 274–5°, $[\alpha]_D^{20}$ + 33.93°, turned FeCl₃ green-black, sol. in cold HNO₃ with green color which became yellow orange with excess KOH, reduced Fehling soln. **VI** was evapd. *in vacuo*, extd. successively with petr.-ether, Et₂O, CHCl₃, H₂O and EtOH. Petr.-ether yielded traces of gentiosterine and fats; Et₂O and CHCl₃ each extd. gentine which was pptd. by petr.-ether; H₂O pptd. more resins and finally EtOH extd. more gentine. The latter was a S-yellow color, giving silky hygroscopic needles from 95% EtOH, m. 266.7°, almost insol. in Et₂O or H₂O, extremely sol. in concd. EtOH, in cold alkalis (lemon yellow color), in H₂SO₄ (yellow-orange color), and in hot HNO₃ (green color changing to chrome yellow), turned FeCl₃ a green color. **IV** on evapn. and extn. with boiling 95% EtOH and digestion for 8 days and further extn. with EtOH gave gentianose, m. 207–9°, $[\alpha]_D^{20}$ 31.74°. The EtOH mother liquors yielded sucrose. Steam distn. of fresh root gave 1% of a yellow-brown oil with an unpleasant odor somewhat like cinnamon oil, which on continued breathing produced nausea (cf. Planché, *Bull. pharm.* 6, 551(1814)). The high % of extractives and of gentiopierin and gentialtheisides, and their ease of extn. by this new procedure suggest the possible *economic value of this root in medicine*. Forty-four references to similar work, many of them old, are included.

C. C. DAVIS

Odor and chemical constitution in the benzothiazole group. M. T. BOGERT and ARTHUR STULL. *Am. Perfumer* 20, 453(1925) — Unoxidized org. S. compds. sufficiently volatile to have any odor at all almost invariably possess a disagreeable one. An exception to this apparent rule is seen in 2-phenylbenzothiazole or "Rosenkörper" of Hofmann. A similar odor is noted in compds. arising from the replacement of the 2-phenyl group by 2-*p*-tolyl, α -furyl or α -thienyl. All 3 melt within a range of 15° and possess the characteristic tea rose or geranium-like odor in greater or less degree. The introduction of vanillyl and piperonyl leads to compds. having a very weak sweet odor recalling faintly that of the initial aldehydes. *p*-Phenylenebisbenzothiazole is, on the other hand, practically odorless.

W. O. F.

Phytochemical notes. 1. ROSENTHALER *Arch. Pharm.* 263, 561–3(1925) — 1. Mannitol in jalap root. An aq. ext. of the coarsely powd. root was definitely shown to contain mannitol in relatively small quantity. 2. Sucrose in belladonna root. An alc. ext. of the root yielded sucrose m. 185–6° and $[\alpha]_D$ 66.5°. 3. Glucoside of HCN from the bark of *Pirus aucuparia* Gärtner. Bark from the trunk contg. 30.7 mg. % HCN yielded on extn. with EtOAc and CHCl₃ too few crystals for the exact recognition of the glucoside, but the mother liquor therefrom has the enzymic index *via* Bourquelot of 560, a value corresponding fairly well with that for mandelonitrile glucoside, namely 517. This view was confirmed by isolation of *l*-mandelic acid from a portion of the mother liquor after treatment with fuming HCl. 4. Occurrence of HCN glucoside in *Achillea millefolium* L. The presence of a glucoside of BzH.HCN was shown, but its exact nature was not detd. 5. Occurrence of HCN in *Chloris petraea*. The presence of HCN, as also of AcMe, was shown in this South African grass.

W. O. F.

Essential oil of manuka (*Leptospermum scoparium*). ROY GARDNER *J. Soc. Chem. Ind.* 44, 528–30T(1925) — The av. yield of oil from the leaves and twigs grown in N. Zealand was 0.4%. The approx. compn. is considered to be leptospermol 3%, terpene 1%, citronellyl cinnamate 6%, acetate, butyrate, etc., of (?) sesquiterpene alc. 14.5%, non-volatile matter 5%, sesquiterpene (by difference) 70.5%. Leptospermol is shown to be a monobasic acid. The sesquiterpene resembles eudesmene in phys. characters and color tests, but gives only a monohydrochloride, whereas eudesmene yields a dihydrochloride.

W. O. F.

Japanese mint oil. W. H. SIMMONS. *Perfumery Essent. Oil Rec.* 16, 378(1925). — Considerable variation exists in the quality of Japanese dementholized mint oil not only between different brands but also between different shipments of the same brand, as much as 7 or 8% being observed. Generally speaking, it is found that as the d. goes

down so the total menthol content falls, a d. much under 0.900 almost invariably corresponding with a menthol content under 50%. The optical rotation of these oils rarely falls below -27° . Adulteration of Japanese mint oil is again rife, a particularly bad example contg. up to 45% petroleum.

Vetivert oil. ANON. *Perfumery Essent. (Oil Rec. 16, 371-2(1925).*—Among the factors considered are cultivation of the grass, extn. of the oil, yield and quality of the oil and phys. characters. A sample of the Java-grown product had d_{15}^{20} 1.017, $[\alpha]_D^{20}$ $42^\circ(?)$, n_{20} 1.524, acid no. 16, ester no. 14, soly. in 80% alc. 1:1. The best vetivert oil of Java has a clear tea color and sweet aroma slightly resembling sandalwood.

Examination of quinine salts for secondary alkaloids. A. DEER, JR. *Pharm. Monatshefte 6, 185-7(1925).*—A simplification of the Ger. Pharm. procedure was notably for quinine sulfate, as follows: In a 100 cc. Erlenmeyer flask dissolve 1 g. of the sample in 40 cc. of H_2O by boiling, close with a stopper and cool quickly with vigorous shaking, then after the addn. of 5 g. of K_2SO_4 shake often for a half hour at 20° (in a H_2O bath), filter through a pledget of cotton, transfer a 20 cc. aliquot of the filtrate to a dry beaker, add 5 cc. of H_2O and 1 drop of 20% NaOH soln. Neither immediately nor later should any turbidity or ppt. appear.

Lemon oil. A. GAWALOWSKI *Pharm. Monatshefte 6, 188(1925).*—Lemon oil contains as its main component (about 90% and more) limonene, citral (about 6%) and in addn. camphene, terpinene, sesquiterpene, terpineol, geraniol, etc. The varying d. (0.857 to 0.863) and m. p. (around 20°), notably also the optical activity (between 57° and 65°), are characteristic of different lemon oils. In this connection attention is directed to eucalyptus and camphor oils (notably their constituents and phys. properties) on account of certain relationships to the possible use of lemon and eucalyptus oils as raw materials in camphor synthesis.

Strontian as reagent for arsphenamine and neoarsphenamine. ALFRED HIRSCH. *Pharm. Ztg 70, 1703(1925).*—A reply to criticisms of Kollé, Bauer and Leupold (cf. C. A. 20, 261).

Decomposability of atropine sulfate. J. BODNAR AND JOHANN FERENCZY. *Arch. Pharm. 263, 566 70(1925).*—Examn. of the aurates and platinites resulting from the treatment of atropine sulfate in aq. soln. indicates a decompn. of this salt to some extent into tropine sulfate and tropic acid, a fact worthy of consideration in applying sterilized atropine sulfate in pharmacol. practice. Atropine nitrate and phosphate are stable under like treatment.

Oleum ferratum concentratum. ERIC WINBERG. *Pharm. Zentralhalle 66, 783-5(1925).*—A procedure is outlined for the prepn. of this product, official in several foreign pharmacopœias, and also a method for detg. the Fe component.

A study of the extraction of opium alkaloids. M. GRABOWSKA AND ST. WEIL. *Bull. trav. inst. pharm. Etat No. 2, 3-36(1925)* (In Polish).—Unripe, unscarified poppy heads were dried at room temp., ground and percolated with 70% alc. contg. AcOH. The percolate was concd. at $47-49^\circ$ and the alkaloids were isolated by the usual methods. The temp. never exceeded 49° . One kg. poppy heads dried at 100° yielded 0.8078 g. morphine and 1.027-1.3403 g. of the other alkaloids, while their proportion was found by other authors to be 1:0.5 to 1:0.9. The authors assume that the original content of the various alkaloids or their mother substances is altered by the action of enzymes and chemicals during storage and extn. The yields obtained by this procedure are not satisfactory, but do not discourage further work on the utilization of the European poppy.

Preparation of iodized oil with 10, 20 and 25% of iodine. MARIA CLOTILDE BIANCHI. *Giorn. farm. chim. 74, 249-51(1925).*—The reaction product of 20 g. I with 30 cc. eucalyptus oil is heated 30 min. in the autoclave to 120° with 180 g. almond or sesame oil. The reddish yellow oil, d_4^{20} 0.980-0.985, contains 10% I and 13.95% eucalyptol. It is perfectly stable and can be given orally or subcutaneously without any ill effect. 20-25% I may be introduced by means of a corresponding quantity of eucalyptol.

Application of fluorescence to chemistry, pharmacy and biology (FABRE) 3. Cr soap (U. S. pat. 1,567,049) 27.

Formamide. R. WIETZEL. U. S. 1,567,312, Dec. 29. An alkyl formate, *e. g.*, Me formate, is treated with NH_3 under pressure to produce formamide.

Vaccines. E. TOENNIESSEN. Brit. 233,377, Nov. 14, 1923. See U. S. 1,514,681 (C. A. **19**, 153).

Remedy for pyorrhea. C. W. MONROE. U. S. 1,567,971, Dec. 29. The gums and affected parts are treated with a soln. contg. NaI and pepsin or a similar enzyme.

Remedy for hemorrhoids. J. KATO. U. S. 1,567,847, Dec. 29. An elec. colloid of metallic Mg is mixed with glycerol, olive oil, liquid paraffin or other inert innocuous oily liquid.

Curing tobacco. A. C. BUENSOD. U. S. 1,568,316, Jan. 5. Tobacco, arranged in rows, is treated with currents of air of a temp. of $35-43^\circ$ and a relative humidity of 70-75% until substantially all the food in the tobacco cells has been consumed. Cf. C. A. **19**, 2390

18 -ACIDS, ALKALIES, SALTS AND SUNDRIES

FRED C. ZEISBERG

Methods for making sulfuric acid. ANON. *Chem. Eng. Mining Rev.* **18**, 11-3 (1925).—An elementary article describing acid plants of Central Mine and Broken Hill Proprietary Mine, Australia. F. C. Z.

Metallic corrosion in concentrated phosphoric acid. FULLER CLARKSON and H. C. HETHERINGTON. *Chem. Met. Eng.* **32**, 811(1925).—Tests of Pb, Duriron, Monel metal, tank-car steel and Al in concd. cold H_3PO_4 and concd. hot $(\text{NH}_4)_3\text{PO}_4$ show that the manuf. of ammonium phosphate can be carried out in a lead-lined wooden tank, with an NH_3 inlet pipe of Monel metal. Tanks and tank cars should be lead-lined, or wood.

E. L. CHAPPELL

Utilization of sulfate obtained as by-product in the manufacture of dichromate. N. F. YUSHKEVICH and I. N. SHOKIN. *J. Chem. Ind. (Russia)* **1**, 33-5(May-June, 1925).—In the manuf. of $\text{Na}_2\text{Cr}_2\text{O}_7$ by reaction of Na_2CrO_4 with H_2SO_4 , anhyd. Na_2SO_4 obtained as a by-product is contaminated with $\text{Na}_2\text{Cr}_2\text{O}_7$ and hence cannot be used. The authors undertook to find a means of purifying this product for glass manufacture. They found that on passing SO_2 through an aqueous soln. of the impure sulfate, the dichromate is reduced thus: $\text{Na}_2\text{Cr}_2\text{O}_7 + 4\text{SO}_2 = \text{Cr}_2(\text{SO}_4)_3 + \text{Na}_2\text{SO}_3$. By subsequent treatment with NaOH , Cr is pptd. and can be filtered off and utilized. Na_2SO_4 remaining in the soln. is sufficiently pure to be used in the glass industry. B. NELSON

Utilizing carbide residue. J. J. MURPHY. *Chem. Met. Eng.* **32**, 800(1925).—Residues from C_2H_2 generators have been used successfully for making lime mortars, causticizing soda liquors, making bleach, in beet sugar defecation, etc. Only when large quantities of the residues are available does it pay to dry and ship the $\text{Ca}(\text{OH})_2$ any great distance. Local markets, however, can usually take all residues produced.

W. C. EBAUGH

Carbon tetrachloride as a fire-extinguishing agent. J. VOIGT. *Chem.-Ztg.* **49**, 937(1925).—V. regrets the propaganda against CCl_4 which has been based on its tendency to form COCl_2 under conditions of use, since this is seldom dangerous under existing conditions, and suggests counter-propaganda.

Carbon monoxide in lime-kiln gases. P. G. GALABUTSKI. *Zapiski* **1924**, 15; *Centr. Zuckerind.* **33**, 1477-8(1925).—A discussion of the reactions by which CO may be formed in the lime kiln. For a kiln burning 50,000 kg. stone per day with a coke consumption of 5000 kg. 1% CO in the gas means a coke consumption of 5500 kg. per day.

W. L. BADGER

Storage and transportation of bromine in metal containers. L. HACKSPILL and RUFFIN. *Chimie et industrie Special No.*, 326-7(Sept., 1925).—Pure dry Br (b. 59°) slightly attacks mild steel (0.12% C) and electrolytic Fe to form a thin film of FeBr_3 ,

which protects the metal against further attack. Pure Br vapor has a similar but much slower action. Of the impurities generally present in Br, C has no action, H_2O causes the formation of a hydrated bromide which does not adhere to the metal, and H_2SO_4 dissolves the $FeBr_3$ to form $Fe_2(SO_4)_3$. Zn is attacked even less than Fe, probably because the $ZnBr_2$ film is more adherent and less porous. H_2O can be removed from Br by Fe filings, which react to form hydrated $FeBr_3$, from which the Br is subsequently recovered. Storage and transportation of Br in Fe might be inadvisable when the Br is to be used in the prepn. of certain org. compds. in which a trace of Fe can be harmful.

A. PAPINEAU-COUTURE

X-ray examination of some NH_3 catalysts (WYCKOFF, CRITTENDEN) 2. S from sulfide ores (U. S. pat. 1,567,916) **9.** Apparatus for producing hypochlorites (Brit. pat. 233,490) **1.** Hydrocarbons and cyanides (U. S. pat. 1,567,241) **21.**

PARTINGTON, J. R.: **The Alkali Industry.** 2nd ed. revised and enlarged. London: Baillière, Tindall & Cox. 344 pp. 12s. 6d. Reviewed in *Ind. Chemist* **1**, 502; *Chem. Age* **13**, 493 (1925).

Concentrating dilute nitrous gases. NORSK HYDRO-ELEKTRISK KVAELSTOF-AKTIESELSKAP. Norw. 41,742, Aug. 17, 1925; Brit. 231,078, May 15, 1924. The gases are absorbed in a soln. of alkali phosphate. The resulting salt mixt. is heated to such a high temp. that the N is sepd. in the form of nitrous gases with regeneration of the alkali phosphate.

Hydrocyanic acid and cyanides. BADISCHE ANILIN & SODA FABRIK. Brit. 233,080, Feb. 19, 1924. HCN is formed by passing formamide or NH_4 formate or their mixt. with a diluent gas over dehydration catalysts (other than those described in Brit. 220,771; C. A. **19**, 707). Bauxite poor in Fe or a product prepd. by applying a paste of Mn carbonate to granulated bauxite and reducing with H or CH_3OH vapor may be used as the catalyst. NH_4 may be used with the reaction mixt. to form NH_4CN and production of other cyanides also is described.

Evaporating to dryness solutions of alkali cyanides. STOCKHOLMS SUPERFOSFATFABRIKS A.-B. Swed. 59,652, Oct. 21, 1925. The soln. is subjected to a sudden evapn. in finely divided state *in vacuo* at a temp. above the sapon. temp. of the alkali cyanides; they are thus obtained free from water of crystn.

Removing free carbon from commercial cyanamide and other metal cyanamides and cyanides. STOCKHOLMS SUPERFOSFATFABRIKS A.-B. Swed. 58,560, April 15, 1925. The materials are at normal, reduced or increased pressure subjected to the action of oxygen or air preferably mixed with other gases inert to C, at such a temp. that the C is oxidized while the N compds. are chiefly left intact.

Ammonia synthesis. I. CASALE. Brit. 233,040, Jan. 31, 1924. In NH_3 synthesis, electrolytically obtained O is used, alone or mixed with air, for the gasification of fuel, and, in admixt. with air, for the combustion of the gaseous products, to yield a gas which, after removal of CO_2 consists of N.

Basic lead sulfate. EAGLE PITCHER LEAD CO. Brit. 233,188, June 26, 1924. Molten Pb (preferably free from Zn) is atomized together with compressed air and gas or other fuel so that a long flame is formed. SO_2 is admitted to the flame and the compn. of the basic Pb sulfate produced is regulated by controlling the proportion of the SO_2 .

Soluble alkali silicates. NORSK HYDRO-ELEKTRISK KVAELSTOF-AKTIESELSKAP. Norw. 41,452, June 15, 1925. Compds. of alkali, N and O are mixed with hydrated SiO_2 and heated to a temp. below the m. p. of the mass.

Anhydrous magnesium chloride. P. COTTRINGER and W. R. COLLINGS. U. S. 1,567,317, Dec. 29, 1925. A film of $MgCl_2 \cdot 6H_2O$ soln. is heated on the surface of a rotating drum which is interiorly heated and the film on opposite sides of the drum is exposed to currents of combustion gases of different temps. After drying, the film is removed from the drum. Cf. C. A. **20**, 97.

Aluminium sulfate. R. MOLDENKE and W. SCHUMACHER. U. S. 1,567,610, Dec. 29, 1925. Bauxite, kaolin, clay or other suitable aluminous material is exposed while heated, to the action of H_2SO_4 vapors, and air is introduced to oxidize the Fe in the material so that it will not be appreciably acted on by the H_2SO_4 .

Sodium thiosulfate. F. RUSBERG. U. S. 1,567,755, Dec. 29, 1925. A soln. contg. Na sulfide and Na sulfite is treated with a gas contg. 32% SO_2 by vol.

Granulating sodium sulfide, bisulfate, etc. CHEMISCHE FABRIKEN KUNHEIM & Co., A.-G. Brit. 233,316, May 1, 1924. Substances such as Na sulfide, $NaHSO_4$ or caustic alkalies are allowed to fall as molten drops on to surfaces (of metal, ebonite,

celluloid, etc., treated with vaseline to prevent adhesion) maintained below the m. p. of the substance.

Aluminium chloride. G. L. PRICHARD and H. HENDERSON. U. S. 1,568,181, Jan. 5. A mixt. comprising bauxite and coke or other aluminous material and C is tumbled down a reaction zone, *e. g.* in a vertical, baffled heating chamber, and Cl is passed in counter-current contact with the mixt. to form AlCl_3 , which is removed from the reaction zone in vapor form and condensed. Cf. *C. A.* 19, 707.

Recovery of aluminium chloride from oily residues. A. M. McAFEE. U. S. 1,568,171, Jan. 5. Oily residues contg. AlCl_3 are heated sufficiently to volatilize the AlCl_3 and a "minimal" partial pressure of AlCl_3 vapors in contact with the residue is maintained. Cf. *C. A.* 19, 726, 1773.

Separating potassium compounds from aluminium compounds. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAP. Norw. 41,581, July 6, 1925. The substances are converted into nitrates and these are treated with HNO_3 . KNO_3 is dissolved but only very little of the $\text{Al}(\text{NO}_3)_3$.

Manufacture of phosphorus and aluminates or alumina. E. COLLETT. Norw. 41,453, June 15, 1925. Raw phosphates are heated with carbon. To bind the CaO present in the raw phosphate materials contg. Al_2O_3 are added, such as bauxite, China clay, common clay or similar substance. The aluminate produced can be worked to alumina.

Apparatus for production of hypochlorites and chlorates. M. WILDERMAN. U. S. 1,568,787, Jan. 5.

Removing sulfur from gas. J. W. COBB and H. J. HODSMAN. Brit. 233,011, Jan. 4, 1924. Partial removal of H_2S from gas is effected by passing the gas (contg. sufficient O) over hot Fe oxide or the like, maintained at a temp. sufficiently high that free S is carried along by the gas, and NH_3 is utilized to remove any SO_2 formed. Residual H_2S may be removed by a cold oxide purifier.

Decolorizing carbon. SVENSKA SOCKERFABRIKS A.-B. Swed. 59,741, Oct. 27, 1925. Org. substances are carbonized in the presence of water-absorbing salts, acids or bases with positive heat of soln. The water-absorbing substance is produced during the carbonization process by smelting or by distn. In the former case the materials are preferably distributed in a thin layer on wire netting or other perforated support in order that the salts, etc., can easily run off.

Polymerized styrene and its homologs. NAUGATUCK CHEMICAL CO. Brit. 233,649, May 7, 1924. A vitreous product which can be cut with a knife is prepd. by polymerizing a mixt. contg. styrene or its homologs to obtain the ordinary resinous polymerization product, depolymerizing this product by dry distn., purifying the product and again polymerizing. A homogeneous mass of polymerized styrene or its homologs is obtained by adding styrene or its homologs to a mass of pieces or powder of the polymer and polymerizing by heating to 180° for 3 hrs. (or for a shorter time under pressure). A powd. polymerized product may be obtained by emulsifying styrene or its homologs with NH_3 soln. and oleic, stearic, palmitic or similar acids. The emulsion is heated to 140° for 12-24 hrs. and may be mixed with gelatin, gum arabic, agar agar, starch, etc. The polymerized product is pptd. by the addn. of MeOH, EtOH, acetone, H_2SO_4 , HOAc, BaCl_2 or any agent which coagulates rubber latex. The product is dried and may be mixed with pigments such as ZnO , CdS or HgS and compressed in a mold.

Tightening and filling composition. M. PERSSON. Swed. 58,819, June 3, 1925. Glue is dissolved in water or milk with a small addn. of AcOH. To the soln. are added mineral and metal salts which form crystals contg. water of crystn. A drying oil is added to the mixt. and pulverized wood and stone to a thick paste and finally MgO and optionally some pigment; the mass is worked to a homogeneous mixt.

Molding sawdust, waste paper, paper pulp, asbestos waste, etc., under heat and pressure. N. C. F. JENSEN. Brit. 233,026, Jan. 28, 1924. Only small quantities of binder (*e. g.* shellac 1-2 1/2%) are used.

Cleaning condensers, pipe systems and radiators. S. GARBARINO. Brit. 233,632, Jan. 21, 1925. Incrustation deposits are removed by use of a soln. formed of H_2O 86.5, HCl 12, CuSO_4 1 and a 25% Na_2SO_4 or NaHSO_4 soln. 1/2 part.

Enamel-cleaning composition. C. W. DRES. U. S. 1,568,323, Jan. 5. HOAc 5, "ammonia" 12.5, pulverized rotten stone 25 and H_2O 57.5%.

Imitation horn. INTERNATIONALE GALALITH-GESELLSCHAFT. Hoff & Co. Brit. 233,181, June 19, 1924. Small quantities of alkylated amines, balsams or other fat solvents which are not readily volatilized are added as clarifying agents to casein compns. which are moistened with a small quantity of aq. liquid and molded under heat and pressure.

Detergent. B. L. BLATT. U. S. 1,567,902, Dec. 29. A compn. for cleaning and "renovating" painted or varnished surfaces comprises Na phosphate 30, Na borate 68 and glue 2%.

Detergent. C. H. EMARY. Brit. 233,280, Jan. 28, 1925. A compn. for cleaning and polishing metals, painted or varnished surfaces, etc., is prepd. by mixing powd. KOH and $(\text{NH}_4)_2\text{CO}_3$ with cold palm oil.

Combined lime-kiln and gas-producer operation. BRITISH AND FOREIGN LIME & POWER CORPORATION, LTD. and T. A. REID. Brit. 233,137, May 3, 1924. In a plant for the production of gaseous fuel from lime-kiln gases, in which a lime kiln burning limestone, dolomite or magnesite is worked in connection with 2 gas producers (each operated alternately as a producer and as a converter for transforming CO_2 into CO), the hot gases from the producer acting as a converter are passed through a retort contg. bituminous coal or other carbonaceous material.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON AND C. H. KERR

Formation of mullite from cyanite, andalusite and sillimanite. J. W. GREIG. *Am. J. Sci.* [5] 11, 1-26 (1926) - See *C. A.* 19, 3151. H. G.

Life of blast furnace linings. M. C. BOOZE. *Iron Age* 116, 1446 (1925). - Changes in operating conditions such as the liberal use of cooling plates generally lengthen the service of silica brick and other refractories for blast furnaces and coke ovens. Red or brownish spots in silica bricks may be burned out under proper atm. conditions.

W. H. BOYNTON.

The plasticity of clay (BANCROFT, JENKS) 2.

Glasses and enamels. GENERAL ELECTRIC CO., LTD. Brit. 233,295, Oct. 14, 1924. The glasses and enamels described in Brit. 223,837 (*C. A.* 19, 1183) are made more resistant to chem. action by increasing the SiO_2 content. The B_2O_3 content is decreased at the same time, to maintain the desired low m. p., and the alk. oxides are preferably replaced in part at least by other oxides such as those of Zn, Mg, Ca, Ba or Li which reduce the coeff. of expansion. The products may comprise: PbO 1, ZnO (or Al_2O_3 , CaO , MgO or BaO) 0.04-0.15, SiO_2 0.3-0.6, Li_2O (or Na_2O or K_2O) 0.04-0.15, Ba_2O_3 0.23-0.35 and coloring oxide 0-0.1 parts. Fluorides such as CaF_2 may be used for producing opaque enamels and refractory oxides and salts of metals may be added.

Furnace for annealing glassware. P. Q. WILLIAMS. Brit. 233,402, Feb. 4, 1924.

Gas-fired recuperative glass furnace with two separate melting chambers in alternating use. O. E. W. WIDLUND. Swed. 59,562, Sept. 30, 1925.

"Modeling clay." E. E. SNOOK. U. S. 1,568,098, Jan. 5. A modeling compn. comprises gelatin glue 8 oz., H_2O 11.5 oz., boiled linseed oil 8 oz., "titanox" 1 lb., bolted whiting 6 lbs., 1 oz., chrome yellow 3 oz. and Me salicylate $\frac{1}{2}$ oz.

"Antislip" tile. F. J. TONE. U. S. 1,567,091, Dec. 29. The tread surface of a burned tile is formed with embedded clusters of abrasive grains, previously bonded by ceramic material, e. g., feldspar and kaolin, fired at 1350° .

Molding press for manufacturing bricks of a porous structure, especially from blast-furnace slag. AKTIEBOLAGET ARCUS. Swed. 59,696, Oct. 13, 1925.

Kiln for burning brick, pottery, etc. W. SIMKIN and E. EVANS (trading as PERFECT KILN Co.). Brit. 233,033, Jan. 30, 1924. •

Porcelain crucible. A. KÖNIG. U. S. 1,567,654, Dec. 29. The bottoms of porcelain crucibles are formed from finely porous material which is melted together with the porcelain and serves to produce a bottom adapted for filtration in chem. analysis.

Refractory material. S. J. LUBOWSKY. U. S. 1,567,445, Dec. 29. Calcined rutile with its particles sintered together is used for making bricks, muffles, crucibles or other refractory chemical-resisting articles.

Crystalline alumina for use as an abrasive. C. J. BROCKBANK. U. S. 1,568,873, Jan. 5. An aluminous ore such as bauxite is fused with a reducing agent, e. g., coke and Fe, and H_3BO_3 and the fused Al_2O_3 is sepd. from the reduction products.

Abrasive disks. H. C. MARTIN. U. S. 1,567,071, Dec. 29. Grains of abrasive material are mixed with shellac in the proportions of about 9:1, the mixt. is spread in a mold upon a backing such as cloth or paper and the material is heated and compressed

to effect agglomeration but leave a porosity of at least about 30% and then baked. Cf. C. A. 19, 1763.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Modern quick-hardening cements. C. T. STEPHENS. *Commonwealth Engineer* 13, 89-91 (1925).—S. gives a short general discussion of high-alumina cements and rapid-hardening port. cements. Differences in compn., manuf. and strength of resulting products are stated. A few estimates upon cost and some information concerning the use of these products in buildings, roads and concrete pipes, are included. L. B. M.

Results of tests with alcement Lafarge. A. P. R. LUND. *Teknisk Ukeblad* 72, 324-7, 335-40, 350-2 (1925).—Alcement, manuf. by the S. t. c. A. me des Chaux & Ciments de Lafarge et du Teil, France, had the following compn.: SiO_2 8.68, insol. 3.49, Al_2O_3 and TiO_2 41.53, FeO 6.38, CaO 40.96, MgO 0.69, SO_3 0.07, hygroscopic water 0.05, and increase in wt. on ignition 0.44%. It was compared with a portland cement of normal compn. The setting properties of the alcement were normal. Notwithstanding an increase in temp. of 15° the setting time was not reduced noticeably even with an initial temp. of water and air of 25° or even 30° . The soundness was satisfactory. The hardening of the alcement was extremely quick. The major part of the ultimate strength was reached in 24 hrs. After 28 days the tensile strengths of the two sand mortars were nearly alike, only with a 10% difference in favor of the alcement, but the crushing strength of the latter was nearly twice that of the portland cement mortar. In concrete the superiority in crushing strength of the alcement was still greater. Humic acids in the sand have only a small influence upon the quality of this mortar. It was very resistant to fire and frost, but less so to rapid cooling in water from a temp. of 1100° . Alcement mortars showed slightly greater resistance to wear. Large test specimens of concrete and reinforced concrete from the two cements all proved great and general superiority of the alcement. C. A. ROBARK

Plastic magnesia. O. C. RALSTON, R. D. PIKE, AND L. H. DUSCHAK. *Bur. Mines, Bull.* 236, 107 pp (1925). Plastic magnesia is defined as a caustic magnesia adaptable to forming Mg oxychloride cement when mixed with a MgCl_2 soln. of proper consistency. Full discussion includes: the constitution of Mg cements, the rate of thermal decompn. of natural MgCO_3 and CaCO_3 , calcination of magnesite for plastic magnesia, methods of judging the quality, recarbonating free lime in burnt magnesia and dolomite, the effect of exposure on plastic magnesia, and the behavior of SiO_2 during the burning of magnesia. W. H. BOYNTON

Jointless (magnesium oxychloride) floors. P. W. BARNETT AND B. BAKEWELL. *Dept. Sci. Ind. Res. Building Res., Bull. No. 1*, 26 pp (1925).—The use of Mg oxychloride cements in flooring compns. is discussed. A description of the constituent materials, methods of mixing and laying, and specifications, is given. A new oxychloride cement is described in which FeCl_2 is substituted for MgCl_2 . This cement is less corrosive than the magnesia-magnesium chloride cements. L. B. M.

Copper as a building material. ANON. *Apparatebau* 37, 326-7 (1925).—Its suitability for roofing is stressed. J. H. MOORE

Use of slag accumulations in industry. KURT ELLERSIEK. *Feuerungstechnik* 13, 245-8 (1925).—To utilize the slag from blast furnaces, cupolas, or furnaces as a building material, in Germany the slag is often ground fine, mixed with water and powd. CaO , pressed, and hardened in steam under pressure, as in the sand-lime brick process. By a new process not yet perfected, a sufficiently basic slag may be used without CaO , the pressed brick being exposed to gases contg. CO_2 , such as blast-furnace gas. E. W. T.

A new impregnating process for mine timbers. E. R. BESEMFELDER. *Braunkohle* 24, 778-82 (1925).—All operations are carried out in a cylinder jacketed for steam heating and for cooling. After charging and heating up, all H_2O is removed from the wood by passing through the cylinder the vapors of an org. liquid such as C_6H_6 , CHCl_3 , CCl_4 , etc.; when H_2O is no longer present in the condensate (from the condenser attached to the cylinder), the cylinder is closed off and cooled; this produces a vacuum within the cells of the wood (which is still warm), while most of the org. liquid condenses on the cold cylinder walls, collects at the bottom, and is pumped out. The cylinder still being under some vacuum, the impregnating fluid is slowly introduced until no more is taken up; this fluid may consist of crude paraffin or montan wax dissolved in some org. liquid. After draining out the excess the cylinder is again heated and steam is passed through

until the solvent used for the impregnating agent has been completely removed and recovered, leaving the wood impregnated throughout with the solid paraffin, etc.

WM. B. PLUMMER

Notes on the antiseptic treatment of Assam timbers for railway sleepers. J. H. WARR AND S. KAMESAM. *Indian Forest Records* 11, 283-388(1925).—To det. the relative economic cost of treatment with various antiseptics, batches of sleepers of 7 different tree species were treated with pure coal-tar creosote, and mixts. of the latter with petroleum, analyses of which are given in the appendix. The method and cost of treatment, the conclusions drawn from the exptl. findings as also the recommendations made are given in detail.

W. O. E.

Determining the penetration of metallic salts in treated wood by means of Röntgen rays. CARL SCHANTZ. *Z. angew. Chem.* 38, 1014 5(1925).—S. takes exception to Moll's conclusions (cf. *C. A.* 19, 3578), claiming that with wood sections 200 mm. and over X-rays will show HgCl_2 penetration beyond the limits shown by the $(\text{NH}_4)_2\text{S}$ stain test.

ALFRED L. KAMMERER

Reducing ores and producing cement (U. S. pat. 1,567,934) 9.

Aluminous cement. U. B. VOISIN. Brit. 233,698, May 6, 1924. Equal vols. of medium hydraulic lime or limestone and bauxite are ground, mixed, briquetted and burnt at 1200-1500° for 12 hrs. to obtain a hard-grinding black clinker which after grinding sets in 2-3 hrs. By employing fat lime and slowing down the burning, a cement is obtained which sets almost immediately.

"Antislip" surface. F. J. TONE and M. L. HARTMANN. U. S. 1,567,772, Dec. 29. Grains of SiC_2 , cryst. Al_2O_3 or other abrasive material for "antislip" floor or tread surfaces are provided with a roughening coating, e. g., of ceramic material or cement.

Imitation marble, etc. MARYLE PRODUCTS, LTD AND A. N. SVANDALSFLONA. Brit. 233,446, Feb. 14, 1924. A thin coating of a mixt. of cement, dissolved casein and H_2O is applied to a smooth, polished or other molding surface and a backing layer of similar compn. admixed with sand or other filler is applied.

Light insulating material for use in building construction. P. MARPILLERO, L. LORENZETTI and I. MARZOLA. U. S. 1,567,663, Dec. 29. Straw, bagasse, wood shavings or other fibrous vegetable material is treated with a soln. of a Mg salt or Na silicate or other fireproofing substance, mixed while still damp with MgO and port. cement or other cementitious material, and allowed to set in molds without compression.

Impregnating wood. AKTIEBOLAGET FURNOS. Swed. 59,162, July 29, 1925. The impregnating agent is applied in exceedingly high dispersion through a spreader with flat slit.

Wood-impregnating agent. SLIPERS AKTIEBOLAGET. Swed. 59,082, July 15, 1925. Non-viscous resin alone or together with peat or wood tar is dissolved in non-viscous mineral oils or hydrocarbons of high b. p.

Apparatus for impregnating wooden articles. J. V. HOLMER. Swed. 59,455, Sept. 16, 1925. The materials resting upon a belt conveyor pass by a spraying mechanism through which the impregnating agent is applied. By means of an automatic opening and stopping device the spreader is kept in function only during the passage of wood to be treated.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

Sardinian fuels, with special reference to the fuels of the Gonnesa basin (Iglesias). R. BINAGHI AND D. ROMOLI-VENTURI. *Ann. chim. applicata* 15, 397-410(1925); cf. *Resoc. Assoc. Min. Sarda* 30, Mar. 3, 1925.—Expts. both on a lab. and on an industrial scale showed that the coal of the Gonnesa basin can be subjected to low-temp. distn. with high yields and economical utilization of all by-products. Different methods from those of Levi and Padovani (*C. A.* 19, 2265) must, however, be employed, for the results in their case were less successful with the same fuel. By low-temp. distn. with catalytic decompn. of the tar and compression of the gas, it was possible to obtain a high yield of excellent primary tar and a coke completely agglomerated, of normal calorific power, contg. 21.5% ash and 6.5% S (mostly incombustible). These promising results agree with those just published by Rodriguez (*Resoc. Assoc. Min. Sarda* Apr. 19, 1925). The large scale expts. were carried out by the Benzonaphthene patented

process (no reference) which is continuous and which can be so controlled that relatively const. yields of any desired products can be maintained. The coal analyzed in %: H_2O 5.75, ash 12.25, volatile 23.25, fixed C 58.65, coke 70.90, N 1.80, calorific power 6524, tar 13.57, aq. NH_3 7.03, gas 5.80. On an industrial scale the % yields were: total tar 11, aq. NH_3 6, coke 70, gas 13, petr.-ether (25–90°) 1.1, benzine (35–150°) 2.2, benzine (100–200°) 0.8, lamp oil (130–250°) 2.2, liquid lubricating oil 4.0, thick lubricating oil 0.5. The basin contains approx. 50,000,000 tons of coal (cf. Taricco, *Boll. Geol.* 49, No. 9 (1922–3); *Boll. Assoc. Min.* 6, No. 5–6, 303 (1924); cf. C. A. 18, 3582), and is one of the most important in Italy. Numerous references to old and little known works are included. C. C. DAVIS

Glasgow and solid smokeless fuel. ANON. *Ind. Chemist* 1, 481–8 (1925).—An illustrated article describing the Glasgow Gas Corp'n.'s recently erected plant for making low-temp. coke by the Maclaurin process. Five producers, internally heated, each having a through-put of 20 tons of coal per day are in operation. From 1 long ton of coal in the present small plant the products are 11 cwt. smokeless fuel, 16 imp. gals. of oil, 16 lbs. $(NH_4)_2SO_4$ and 69 therms of gas. F. G. R. ARDAGH

Pulverized fuel in European plants. C. H. S. TUPHOLME. *Power Plant Eng.* 29, 635 (1925).—British and French power plant engineers are finding that good pulverized coal systems approach the maximum efficiency of combustion. K. C. B.

Economizes fuel in tinning. R. A. FISKIE. *Iron Age* 116, 1665–8 (1925).—A saving of 3.52 lbs. (1.6 kg.) of coal per base box of tin plate is effected at the Standard Tin Plate Co., Canonsburg, Pa., by using producer-gas equipment. The quality and quantity are also improved. Coarse coal alone is used. Low velocities are obtained in the gas flues and gas leaks are avoided. The general plan is illus. W. H. B.

Synthetic motor fuels. R. FURNESS. *Ind. Chemist* 1, 475–80 (1925).—From the point of view of cost of production in competition with gasoline as motor fuel, F. discusses at some length the following processes: (1) alc. by fermentation, (2) synthetic CH_3OH , (3) CH_3OH from CH_4 , (4) synthol, (5) synthetic C_6H_6 , (6) synthetic C_2H_5OH from C_2H_4 , (7) the same from carbide. Much information regarding conditions, yields and costs for each of the above is given. Gasoline will continue to dominate the liquid motor fuel market for such time as its present price is maintained. Synthetic CH_3OH and liquid fuels produced by some simple, catalytic gas reactions are its most likely competitors. Fermentation alc., synthetic C_2H_5OH either from C_2H_2 or C_2H_4 , and synthetic C_6H_6 cannot hope to compete with gasoline. F. G. R. ARDAGH

The fuel oil situation as it affects gas company operation in California. W. M. BERRY AND C. C. BROWN. *Ind. Eng. Chem.* 18, 83–4 (1926).—The economic factors affecting the production of oil gas in Calif. and Ore. are discussed. Capital investments to date total over \$152,000,000. The price of the fuel oil (16° to 18° Bé.) has increased from 70¢ to \$1.65 per bbl. in the past 10 years. This is partly offset by recent improvements in gas making: high-grade briquettes made from the C which is a by-product of the oil-gas process and the recovery of benzene from the gas. The perfection of the liquid purification process for removing H_2S and the recovery of the S in a very pure state have permitted the use of higher S oils for gas making. The Calif. utilities companies and the U. S. Bur. Mines have started a cooperative investigation to det. the value for gas-making purposes of the sub-bituminous and lignite coals of N. Calif. and neighboring states. W. W. HODGE

Equilibrium boiling points. W. A. WHATMOUGH. *Ind. Eng. Chem.* 18, 43–5 (1926).—A sketch and description of the equil. b. p. app. are given. The procedure is outlined together with a table of results, tabibus gasoline being used. With rates of distn. from 10 to 45 cc. per min. the observed equil. b. ps. should not vary more than $\pm 1^\circ$. From 250 cc. to 1 l. of the liquid fuels were used for making the detns. Table II gives the equil. b. ps. and approx. percentages Engler fractionation point at equil. b. ps. for 11 gasolines, 5 kerosenes, 6 motor benzenes, and 10 power alcs. and mixts. These data indicate that the 80 to 85% point on the Engler distn. curve is correct as regards equil. b. ps. of kerosenes and American gasolines; the 60 to 70% is more usual for the more volatile gasolines used in the British Isles; the aromatics range from 60 to 85%; azeotropic admixtures contg. alc. show extreme variation between 50 and 90% in a single series. A set of Engler distn. curves of gasoline-alc. mixts. is given and the significance of the general shapes and of the changes in directions of the curves is discussed. U. S. A. cracked distillates and East Indian aromatic fuels ordinarily of little value because not sprayable become equally effective, in a dry gas carburetor, to gasoline at the usual mixt. temps. (40° to 60°) on reducing equil. b. ps. with the aid of alc. W. prefers the actual detn. of equil. b. ps. at approx. atm. pressure to accepting the 85% point on an Engler distn. curve, as the best indication of the manifold distribution

characteristics and guide to the volatility of a fuel under the variable running conditions of a road motor. W. W. HODGE

The adsorption of gas by solid combustibles during drying. R. VONDRÁČEK AND B. HLAVICA. *Bull. soc. chim.* **37**, 1310-20(1925).—Various solid fuels were dried in a U-tube at 105° in currents of various gases, the H₂O evolved being detd. by a CaCl₂ tube. The H₂O recovered (expressed as % of original wt.) minus the observed loss in wt. represents, when positive, an adsorption of gas, and when negative means that the gas passed during drying is less adsorbed than the gas originally adsorbed on the fuel. This difference for the various fuels and, resp., N₂, H₂, air and CO₂, was as follows: lignite, -0.09, -0.17, +0.20, +0.76; non-coking coal, -0.11, -0.20, +0.49, +1.59; gas coal, +0.01, -0.03, +0.14, +0.75; semi-coke (from lignite at 500°), +0.05, -0.43, +0.23, +4.87. The rate of exchange of adsorbed gases is shown by the fact that a sample of semi-coke weighing 1.454 g. after drying and cooling in CO₂ came to equil. at 1.4258 g. in dry air within 60 min., similarly a sample weighing 1.3387 g. after drying and cooling in H₂ came to equil. in air at 1.3442 g. within 45 min. WM. B. P.

Combustion calculations. A. B. HELBIG. *Z. Ver. deut. Ing.* **69**, 1323-4(1925).—A discussion of such calcs., and a formula for calcg. the heat of combustion of fuels (cf. C. A. **19**, 2120). WM. B. P.

Flue explosions. E. H. HAMILTON. *Mining & Met.* **6**, 539(1925).—H. believes explosions in flues from smeltering units are due to the presence of too much unroasted pyrite in the charge. Preliminary results are tabulated on an attempt to det. whether certain pyrite ores are more apt. than others to cause explosions. W. H. B.

Coal deposits and industry of Russia during and after the World War. ALFRED FABER. *Tier* **23**, 530-1(1925).—A brief discussion, no actual statistics being given. WM. B. PLUMMER

Analyses of Alberta coals. EDGAR STANSFIELD, R. T. HOLLIES AND WM. P. CAMPBELL. *Sci. Ind. Research Council of Alberta Rept. No. 14*, 9-63(1925).—Typical, max. and min. analyses (proximate only) are given for the coals from each of 62 districts which are located and described by various maps. The limits between which these coals vary is represented by the following analyses (as mined): Crowsnest area, District A, coking, H₂O 2.1%, ash 16.2, volatile matter 23.1, fixed C 58.6, S 0.5, gross heating value 12,400 B.t.u./lb., Castor area, District A, non-coking, H₂O 24.4%, ash 5.9, volatile matter 30.2, fixed C 39.5, S 0.3, gross heating value 8,840 B.t.u./lb. Most of the coals from the various districts resemble the latter example more closely than the former. Maps of the whole area (Alberta) are given showing lines of equal calorific value and lines of equal % H₂O for the various deposits. WM. B. PLUMMER

Coal liquefaction. FRIEDRICH BERGIUS. *Z. Ver. deut. Ing.* **69**, 1313-20, 1359-62 (1925).—A general discussion of the B. process for liquefaction of coal by heating with H under pressure. The yields of oil and solid residue are given for approx. 120 lab. tests (2 l. bomb) on various coals. The effect of pressure on the process is shown by the following 3 tests: starting pressure (cold) 100 atm., yield of solid residue 11.5%; 75 atm., 17.2%; 50 atm., coking but no liquefaction; evidently the starting pressure should be as high as possible. The optimum operating temp. for most coals is 450-80°. The influence of the coal ash on the process is obscure but is being studied. The distribution of O, N and S in the process and its products is briefly discussed. The gas yield is 15-25% by wt. of raw coal and consists mainly of CH₄ and homologs. In large-scale continuous operation the yields per 1000 kg. raw coal (6% ash) are 445 kg. oil, 210 kg. gas, 75 kg. H₂O, 5 kg. NH₃, 15 kg. losses and 350 kg. of solid residue contg. oil and C, by the coking of which further yields of 80 kg. oil, 25 kg. gas, and 240 kg. coke are obtained. Schematic plant diagrams, flow sheets, and photographs of a com. plant are given. The H supply (5% of raw coal by wt.) may best be obtained by decomposing with steam approx. 0.5 of the gas made in the process; the H need not be over 80% pure so that the gas made during the last part of the coking period in ordinary coke ovens may be used directly. In the continuous com. process pressures of 120-150 atm. are used, the reaction chamber being jacketed and externally heated by hot inert gases (to prevent local overheating) suitably recirculated and recuperated. WM. B. P.

Chemistry of combustion of pulverized coal. S. C. MARTEN. *Power Plant Eng.* **29**, 1091(1925).—Conditions of air supply for economic combustion are: (1) The gaseous constituent must be perfectly mixed with the proper amt. of air. (2) A blast of air should impinge continually on the solid particle until its combustion is completed. K. C. BERSON

Atomized coal system of non-ferrous melting. R. BLACK AND C. L. SHAFER. *Metal Ind.* (N. Y.) **23**, 403-4(1925).—Atomized coal system is a name applied to the use of specially prepd. bituminous coal for melting non-ferrous metals (crucible type

furnace). All the coal must pass a 200-mesh screen. The prepn., burning, theory of the practice, the type of furnace used, cost of atomizing and melting, and the burning installation are described.

W. H. BOYNTON

Distillation of coal and tar by metal baths. PROCKAT. *Z. Ver. deut. Ing.* 69, 1417(1925).—A brief description of the Piron-Caracristi coal distn. process, and the T. I. C., Blümner and Graefe-v. Walther tar distn. processes, all of which use molten metal baths as the heating agent.

WM. B. PLUMMER

Some tests on a two-stroke cycle oil-engine. E. A. ALLCUT. *Proc. Inst. Mech. Eng.* 1925, 849-909.—A detailed discussion and full data of tests on a two-stroke heavy oil engine rated at 25 brake h. p., having crank case compression, hot bulb ignition, 1 vertical cylinder 9.5 in. diam. with 11 in. stroke. Thermal efficiencies based on brake h. p. in the various tests were 19.50-21.83%, based on indicated h. p. 24.79-26.87%.

WM. B. PLUMMER

The possible use of Philippine coals for liquid fuel. V. G. LAVA. *Philippine J. Sci.* 28, 193-204(1925).—Since certain low-grade Philippine coals tend to disintegrate and crumble on storage the present exhaustive study of their utilization as *colloidal fuels* has been carried out. Results are given for 4 coals of which those for Gotas coal only will be reported here, the other results being similar; this coal had 3.16% moisture, 24.08% volatile combustible matter, 61.12% fixed C and 11.64% ash. The crude oil used in the tests had a viscosity of 64.4 sec. Saybolt Universal at 26° and a C residue of 1.82%. The soap used for prepg. the oil emulsions was prepd. from 100 g. of coconut oil by sapon. with 425.6 cc. of 0.1 N alkali, added after sapon. to 500 cc., both Na and K soaps being used. The procedure was to add the oil slowly to the desired amt. of soap soln. with const. mech. stirring, and then to add 54 parts by wt. of the emulsion to 46 parts of the coal which had been ground to pass 200 mesh; addn. of the coal to the emulsion caused breaking and rapid settling. Relative stabilities are illustrated by the following: % K soap in emulsion (before addn. to coal), 4.5, 3.6, 2.5, 1.5; % H₂O, 13.9, 10.9, 7.7, 4.0; life of emulsion alone, days, 90, 90, 49, 2; life of suspension, after addn. to coal, days, 120, 120, 120, 2. With the Na soap, % soap 4.2, 3.3, 2.35, 1.2; % H₂O, 14.2, 11.2, 7.8, 4.1; life of emulsion alone, days, 90, 60, 3, 0.5; life of suspension, after addn. to coal, days, 120, 120, 120, 1. The above suspensions, except in each case the one contg. the lowest % soap and H₂O, were "easy to stir." The viscosity of the suspension prepd. from the emulsion contg. 4.2% Na soap is given as 2.75 Engler hrs. at 28-9°. In general the lower the % H₂O the greater the viscosity and the less the stability, while the greater the % soap the greater are both the viscosity and the stability. The observed calorific values (B. t. u./lb.) were: oil, 10620; coal, 7266; for the various suspensions as above prepd., 8100-8700. Some differences were noted between the coals used, those having the higher % volatile matter giving the less stable suspensions. The suspensions as prepd. were in general suitable for com. utilization. Expts. were preformed, but not reported, on the use of tar as a stabilizing agent for coal-oil emulsions.

WM. B. PLUMMER

The economics of coal carbonization in rotary retorts. M. DOLCH. *Brennstoff-Chem.* 6, 285-90(1925).—D. severely criticizes a previous article by Roser (C. A. 19, 2874). He finds that retort capacities actually found by R. through tests are only 72 to 86% of the 120 ton per day claimed by the latter in his general statement. R. ests. mfg. cost at 9.50 M. per ton and the values of the products at 11.60 M. D. ests. that the former may reach 12.50 M. He calcs. heating costs at 1.39, 1.60 and 0.78 M. per ton from R.'s data for bituminous coal, cannel and brown coal, resp., whereas R.'s figures are 2.00, 1.50 and 2.00. He also considers R.'s value for semi-coke (1.75 M.) per ton of raw coal too low and 4.80 for the gas too high. E. ROSER. *Ibid* 290-1.—R. replies that: 1. Test figures given should not be taken for the calcn. of the best working capacities. 2. Brown coal is not charged raw—with 53% moisture as assumed by D.—but previously dried by waste heat. Cost figures are based on the dried material. 3. The main object of retorting is production of hydrocarbons and cheap semi-coke usable as powd. fuel without further expensive treatment. M. DOLCH. *Ibid* 291.—D. does not consider that R. has adequately answered his criticism. J. D. DAVIS

The hydraulic process for recovery of peat. G. STADNIKOV. *Brennstoff-Chem.* 6, 271-7(1925).—This process, introduced by R. Klasson and V. Kirpichnikoff, has been operated for several years at Ussk in Russia and at Schwaneburg in Germany. It consists in disintegrating the peat bog with water streams—300 lb. pressure—pumping out with centrifugals and spreading through pipes on drying fields to form a layer 20 cm. thick. In this furrows are cut, for efficient drying, by a special tractor-driven roller. A single unit of the plant will recover 20,000 to 30,000 tons of air-dried peat per year. The process effects a saving of about 40% of cost of production of air-dried peat and the

product contained less ash than that of older processes. Draining and drying of the moist peat is now facilitated by coagulation with Fe hydroxide soln.—1 vol. Fe soln. contg. 0.04% Fe to 2 vols. peat. The coagulated air-dried product is best de-watered by pressure with addn. of dry peat powder—the Madruck process. J. D. DAVIS

A colorimetric method for determination of the degree of humification of peat. G. STADNIKOV AND S. MEHL. *Brennstoff-Chem.* **6**, 317-22(1925).—The method consists in comparison of a 2% Na_2CO_3 soln. of the humic acids from peat in a colorimeter with a standard humic acid soln. prepd. from peat. For prepn. of the standard peat is first extd. with C_6H_6 to remove resins, then heated for 2 hrs. on the water bath with 2% soda soln. Dissolved humic acids are filtered off and pptd. with HCl. This ppt. is filtered, washed and preserved as a paste to which 0.2% salicylic acid is added to prevent fungus growth. Standard humic acid soln. is prepd. by dissolving the paste in 20% soda soln. and dilg. so that 1 l. contains 0.2 g. dry humic acid. The sample of peat for the test is treated with an excess of 2% soda soln. for 24 hrs. with frequent shaking, quickly filtered and compared with the standard. The effect of time and temp. on treatment with Na_2CO_3 and concn. of Na_2CO_3 is detd. The method gives lower results than the oxidation and direct weighing methods, but it is rapid and has some tech. application. J. D. DAVIS

High-pressure inclined tube boilers for wood, peat, or brown coal firing. H. F. LICHT. *Braunkohle* **24**, 799-803(1925).—Installations for each case are briefly described, drawings being given in some detail. WM. B. PLUMMER

Recovery and utilization of natural gas in Siebenbürgen. H. LININGER. *Z. österr. Ver. Gas- u. Wasserfach.* **65**, 184-91(1925).—The gas from this district (now Roumanian) consists almost entirely of CH_4 , a typical analysis being 99.0% CH_4 , 0.4 O_2 , 0.1 H_2 , 0.2 N_2 . The gas strata are 70-400 m. deep, the rock pressures being 20-30 atm. The area producing in 1913 was 516 sq. km., the production of the largest well being 800,000 cu. m./day. A brief discussion is given of methods of drilling, capping, reducing and distributing and of burners and combustion methods used. WM. B. PLUMMER

Report of the Fuel Research Board for the period ended 31st December 1924. R. T. THRELFALL, et al. *Dept. Sci. Ind. Research* **1925**, 71 pp.—Plans, photographs, etc., of H. M. Fuel Research Station (Greenwich) are given; also a bibliography of official publications and of those of individual members of the staff. Investigations performed there and elsewhere (all previously reported) on steaming in vertical gas retorts with and without oil injection, low-temp. carbonization in continuous vertical and horizontal externally heated retorts, benzene and alcohol as motor fuels, peat utilization, and other miscellaneous problems are briefly discussed and significant data summarized. WM. B. PLUMMER

Concordant nomenclature for technical (heating) gases. ANON. *Z. angew. Chem.* **38**, 925-9(1925).—A tabular grouping of manufactured heating gases is given, divided into groups, classes and sub-classes. The more important cases are further discussed and defined in the text. WM. B. PLUMMER

Composition and utilization of (mineral) coal gas. HEINRICH HOCK. *Z. angew. Chem.* **38**, 915-7(1925).—Gas yield and compn. from 5 German mineral coals carbonized on a com. scale in rotary retorts at 600° are given. A typical set of results follows: Hardenburg coal 5.0% H_2O , the coal dried at 110° having ash 12.0%, volatile matter 33.0%, S 1.3%, heating value 7000 kg. cal./kg.; gas yield 94 cu. m./1000 kg. or 7.7% by wt.; gas compn. CO 7.5, $\text{CO}_2 + \text{H}_2\text{S}$ 5.8, O_2 0.4, H_2 23.5, CH_4 45.3, C_2H_6 and homologs 6.4, "light oils" 2.0, olefins 4.4 and N_2 4.7%. WM. B. PLUMMER

The presence of iodine in water gas. HENRIK MOHORČIČ. *Chem.-Ztg.* **49**, 925 (1925).—The observation has been made that when HCl is spilled on hot Cu gauzes used in the lab. as supports over gas burners, an evolution of reddish fumes and smell of I are caused. It is therefore concluded that the water gas used (made from a brown coal) contains I. WM. B. PLUMMER

The evaluation of hot and cold producer gas from brown or mineral coals on the basis of the index number. HERMANN BECKER. *Braunkohle* **24**, 793-9(1925).—The index no. is the heating value/kg. flue gases, both being taken per unit of fuel gas. Extensive tabulations, etc., are given. Conclusion: The resp. values of cold producer gas from brown coal, mineral (bituminous) coal, and brown coal briquettes stand in the ratios of 1:1.05:1.15. Factors entering into the question of hot vs. cold gas for various purposes are briefly discussed. WM. B. PLUMMER

The determination of methane and hydrogen in illuminating gas. WILHELM STEUER. *Chem.-Ztg.* **49**, 901-2(1925).—Attempts were made to oxidize first $\text{CO} + \text{H}_2$ and finally CH_4 (after CO_2 , illuminants and O_2 had been previously removed) by

the use of a Pt or Pd catalyst first at 150° and finally at a red heat. Expts. showed, however, that the temp. necessary completely to oxidize the CO was so high that some CH₄ was attacked. The method finally outlined is therefore to remove the CO as usual, add O, oxidize the H by the Pt at 150°, det. the contraction, and finally oxidize the CH₄ at a red heat. The oxidations are carried out in a gas-heated SiO₂ capillary contg. a short piece of Pt wire.

WM. B. PLUMMER

Use of oxygen in gas producers—experiments give affirmative answers to queries propounded by L. J. Willien. A. H. WHITE AND H. G. CHAMBERLIN. *Am. Gas Assoc. Monthly* 7, 757-60(1925).—A description of expts. carried out in a lab. app. consisting of a vertical 2.5 in. diam. coke-filled furnace 36 in. high, with windings for elec. heating and suitably insulated. The furnace was heated to equil. at the max. temp. which the windings would stand (1800-2000° F.), when O steam mixts. were passed in while the elec. heating was maintained. Results of a representative run follow: av temp in bottom of coke 1927° F., steam admitted 0.202 lb/cu. ft. gas, steam decomposed 42%, av. depth of coke bed 25 in., O admitted 0.175 cu. ft./min., gas make 3.84 cu. ft./cu. ft. O or 19.8 cu. ft./sq. ft./min., heating value 242 B. t. u./cu. ft. gas compn. CO₂ 23.1, O₂ 0.2, CO 26.7, H 41.3, CH₄ 1.1, N₂ 4.5%. In so small an app. the use of elec. heating to eliminate radiation losses is necessary, but this limits the temp. used to under 2000° F., the effect of this low temp. and of the shallow fuel bed being shown in the high CO₂ content of the gas. The temp. in the bottom of the coke bed was lowered to 1609° F. by the use of 0.233 lb. steam/cu. ft. gas (steam 34% decomposed) and to 1206° F. by the use of 0.275 lb. (28% decomposed). This shows conclusively (cf. C. A. 19, 1485) that the temp. is readily controllable by steam during gasification with O. [ABSTR.—The H₂O decomposed as detd. from the O balance, calcd. from the O consumption and gas compn. as stated, is 0.01 lb./cu. ft. gas, whereas the value given is 0.085 lb./cu. ft. Some question may therefore be raised as to the correctness of the steam consumptions reported.]

WM. B. PLUMMER

Why not gas motors again? FR. SCHAFER. *Gas u. Wasserfach* 68, 783-6(1925).—Cost comparisons of elec., gas and Diesel engines are given in which the gas engines show up very favorably.

WM. B. PLUMMER

Production of neutral ammonium sulfate in gas works. D. STAVORINUS. *Gas u. Wasserfach* 68, 776-8(1925).—Neutral (NH₄)₂SO₄ may be obtained by running the saturators slightly alk., by washing the salt (as ordinarily prepd.) with H₂O or dil. NH₃ soln., by treating the salt with gaseous NH₃ or by mixing with it a small quantity of some alk. solid substance. Of these the first method involves too much danger of discoloration by Prussian blue formation, the best method being to wash the salt with dil. aq. NH₃. The salt being at a temp. of not over 60°, 180 kg. is whizzed in an ordinary centrifugal drier until dry, when 13 l. of 0.3% aq. NH₃ is sprayed over it. The wash liquor is returned to the NH₃ saturators.

WM. B. PLUMMER

Economies of the reverse blast. A. C. HOWARD. *Am. Gas Assoc. Monthly* 7, 579-84(1925).—This operating procedure is intended primarily for use with bituminous coal in water gas sets. The latter part of the air blast is reversed, being sent down through the superheater, up through the carburetor, and down through the generator fire. The CO in the reversed blast gases leaving the bottom of the generator is higher than in the ordinary blast gases, so that the gases may be sent directly to the wash box. No blow run is used, the division of the rest of the cycle being normal. Advantages claimed for the process are higher av. fire temp. and lower max. fire temp. at the end of the blast, improvement of clinkering conditions, removal of C deposits in the carburetor during the reverse blast, increase of set capacity, decreased generator fuel, and the elimination of the hot valve, reversing valves being installed in the double inlet tar batter. Since the bottom of the generator must be direct-connected to the tar batter there is, however, the danger of introducing air into the cold finished gas if the valves in this line leak during the up blast.

WM. B. PLUMMER

How can unused heat be made useful by means of work? J. KAISER. *Z. Bayer. Rev.-V.* 27, Nos. 20-2(1923); *Feuerungstechnik* 13, 162-3.---The heat-pump can make available heat otherwise lost in flue gases, vapors from drying ovens, waste warm water, etc. The relative merits of CO₂, NH₃, SO₂, Et₂O, EtOH, and H₂O as working substances are considered. The best working substance depends on the temp. range to be employed. Calcs. are given to show that the app. would be of practicable size.

E. W. T.

The tar quest

economic situation requiring the use of low-grade solid fuels, the high tar yield from them is being down to motor fuels, rather than as a process whose chief economic advantage lies in these high yields of tars of high tar acid content.

W. B. PLUMMER

Chemical composition of the tar obtained by distillation of coal from Lupeni (Roumania). E. GEORGACIOPOL. *Bul. soc. române de stiinte* **27**, 37-49(1924).—The compn. of the coal in question is closer to that of lignites than of bituminous coals. The compn. and yields of the *volatile hydrocarbons* and tar obtained on distn. and of the by-products which can be extd. from them are given in detail. A. P.-C.

Determination of primary tar yield by the aluminium retort assay. H. BROCHE. *Brennstoff-Chem.* **6**, 292-4(1925).—Incomplete recovery of water from the (tar + water) distillate by older methods has led to high results for tar. B. recommends the xylene distn. method used by Erdmann (*Z. angew. Chem.* **27**, 52(1914)) for water detn. as accurate to 99.5%. The distillate from the retort is caught in a 300 cc. Jrlenmeyer flask cooled in ice. After collection 200 cc. xylene is added, the flask is connected to a vertical condenser and the xylene is distd. into a 150 cc. measuring tube with a thin stem graduated in 0.01 cc. The stem is calibrated and a correction is applied for meniscus depressions at the water-xylene interface. J. D. DAVIS

Tar recovery in brown coal producer plants. E. F. GIESELER. *Chem.-Ztg.* **49**, 934 5(1925).—A brief discussion of the factors detg. the economic desirability of tar recovery in producer plants. WM. B. PLUMMER

The volatile matter given off by semi-coke at various temperatures. H. TROPSCH AND E. DITTRICH. *Brennstoff Chem.* **6**, 301 3(1925).—Coke samples were prepd. in the Fischer Al retort, max. temp. 500°. These were outgassed both *in vacuo* and at atm. pressure at 500-1000°. In both cases max. gas evolution was observed at 700°. Volumetrically the gas was largely H₂; unsatd. hydrocarbons were absent; satd. hydrocarbons were present in appreciable amts., the highest yields of the higher homologs resulting from outgasing *in vacuo*. Above 900° no hydrocarbons were obtained. The compn. of the volatile products (% by weight at 500° to 1000°) was CO₂ 8.9, O₂ 1.1, CO 13.5, H₂ 14.1, C_nH_{n+2} 9.3, N₂ 11.1, NH₃ 3.0, H₂O 36.0. J. D. DAVIS

Gas coke for domestic firing. RIEDL. *Feuerungstechnik* **14**, 19(1925).—R. announces a new domestic stove for gas coke, characterized by an iron fire-box, air-cooled to prevent clinker, and having openings for secondary air, together with a baffle to aid in mixing the secondary air with the CO. ERNEST W. THIELE

Pulverized-coke-breeze firing. H. W. BROOKS. *Blast Furnace & Steel Plant* **13**, 493-4, 502(1925); cf. *C. A.* **19**, 3369. —A discussion. The difficulties of pulverized C are bridging the gap between the temp. of burning C (450°) and the ignition point of CO (643°), and the abrasiveness of the fuel. B. discusses the cost of pulverizing and shows the cross section of a boiler furnace designed to burn coke breeze in combination with a gas fuel. The decision regarding the use of coke breeze is dependent upon the character and quantity available, and upon economic conditions. By means of tumbler tests the pulverizer maintenance cost may be predicted with reasonable certainty. W. H. BOYNTON

Thermal decomposition of cellulose under hydrogenation conditions (BOWEN, et al.) **23**. **Explosivity of brown coal dust (WEISS)** **24**. **Catalytic combustion (I) union of CO and O in contact with a Au surface (BONE, ANDREW)** **2**. **Combined lime kiln and gas producer operation (Brit. pat. 233,137)** **18**. **Rectifying system for separating constituents of gaseous mixtures (Brit. pat. 232,986)** **13**.

MILES, W. M.: **The Chemistry of Power Plant.** London: E. Benn, Ltd. 144 pp. 6s. Reviewed in *Ind. Chemist* **1**, 502(1925).

Fuel. G. E. RICE and E. J. JOHNSTON. *Brit.* **233,248**, Nov. 3, 1924. Fuel blocks are formed with a core comprising coal dust, CaCO₃, MgCO₃ or other Mg. compd. and sea water, an inner coating of the same ingredients except that the coal dust is omitted, and an outer coating of the same ingredients with the addn. of ground spent oil shale and a crude petroleum jelly.

Fuel mixtures. T. H. BUTLER, F. J. W. POPHAM, J. C. MANN and H. W. ROBINSON. U. S. 1,567,235, Dec. 29. In prepg. homogeneous mixts. of pitch and petroleum residue, the pitch is heated substantially above its m. p. to facilitate mixing.

Motor fuel. L. DE FLOREZ. U. S. reissue 16,239, Dec. 29. See original pat. No. 1,437,045 (*C. A.* **17**, 870).

Use of hydrogen and kerosene together as fuel for aircraft engines, etc. AIRSHIP GUARANTEE CO., LTD. AND C. D. BURNEY. *Brit.* **233,023**, Jan. 26, 1924.

Fuel briquets. F. E. HOBSON. *Brit.* **233,463**, Feb. 22, 1924. Mech. features of

forming scored bars from mixts. such as distd. coal residue 67, distd. sawdust residue 23 and asphaltic binder 10%.

Coking fuel briquets. WOODALL-DUCKHAM (1920), LTD. AND A. M. DUCKHAM. Brit. 233,508, April 25, 1924. Fuel briquets formed of blended coal and which do not tend to soften or swell are carbonized in a continuous vertical retort at high temp. Pitch may be used as a binder and recovered for re-use by volatilization.

Drying coal or other materials by combustion gases. M. D. JONES. U. S. 1,568, -738, Jan. 5.

Gas production. H. O. LOEBELL. Brit. 233,038, Jan. 31, 1924. A mixt. of water gas and coal gas is produced by maintaining a high-temp. zone in the lower portion of the fuel column of a gas producer by blasting air through it downwardly, burning the blast gases in regenerators and passing steam from the regenerators up through the heated zone and the water gas generated through the fuel column in the upper part of the producer, which is preferably charged with a mixt. of coal and coke. Numerous details of procedure are described.

Gasifying and carbonizing coal, etc. H. MACAUX. U. S. 1,567,967, Dec. 29. Finely divided coal or similar material is continuously insufflated into chambers previously heated to redness, and there is simultaneously injected into these chambers a H-contg. gas in such proportion that the partial tension of the H is constantly maintained at a higher degree than the tension which would result from the dissociation of the hydrocarbons contained in the coal and disengaged by its pyrolytic decompn. Gases produced are removed without allowing them to traverse a layer of red hot coke.

Hydrocarbons and cyanides. J. C. CLANCY. U. S. 1,567,241, Dec. 29. Comminuted coal, sawdust, peat, bitumen, lignite or other carbonaceous material is destructively distd. in contact with molten NaCN or other alkali metal cyanide. Volatile reaction products are collected and the distn. residues are subjected to a cyanide-forming reaction to regenerate cyanide decomposed in the distn. and form additional cyanide.

Treating coal tar. K. W. NIELSEN. Danish 35,094, Sept. 21, 1925. The content of bitumen, the resistance to the action of air and the viscosity are all increased by treating with air under heating in the presence of HNO_3 and nitrogen oxides.

Fractional distillation of tar oil or similar materials. A. M. DUCKHAM and J. S. MORGAN. U. S. 1,568,886, Jan. 5. The material is caused to pass between a solid surface such as a revolving drum immersed in molten metal, e. g., molten Pb, and the surface of the molten metal itself. This treatment is repeated, with the residue, at diff. temps.

Still for tar, crude petroleum, etc. J. L. MAJOR and B. TAYLOR. Brit. 233,419, Feb. 7, 1924.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

F. M. ROGERS

The estimation of water in oils and fats. W. M. SEABER. *Ind. Chemist* 1, 469-72 (1925).—The usual difficulties encountered are discussed, followed by a short description of many well-known methods. S's method is a modification of Dean's and Stark's distn. method for moisture in petroleum products. The sample is placed in a 150 cc. flask provided with a dropping funnel and an inverted U-shaped delivery tube connected at the other end to a U tube immersed in a beaker of cold water. The condenser U tube has a bulb of approx. 20-25 cc. blown at the bottom of the U and contains somewhat more than enough Na_2CO_3 to take up all the H_2O distd. from the sample (the min. amt. is 6 pts. by wt. to 1 pt. of H_2O). Run 10 cc. of dry xylene into the flask contg. the sample and start distn. slowly at first, then faster. Add 5 cc. more xylene and finally a further 10 cc. Shake the U tube to allow Na_2CO_3 to come in contact with any water, carefully pour off the xylene and add about 10 cc. of light petroleum ether. Repeat 3 times and finally drain off the ether as completely as possible. Place the tube with legs horizontal and one leg vertically above the other so that as the ether vaporizes it will flow out of the lower leg. Maintain the temp. at 35° to 45° for 30 to 45 min., and then weigh. If the day is unusually humid or dry it is advisable to run a blank. A no. of detns. are recorded and a cut of the app. is shown. E. G. R. A.

Analysis of transformer oils. SVERRE LAUNY. *Tids. Kemi Bergv.* 5, 196-203, 213-5(1925).—Various methods in use are briefly mentioned and the B. B. C. method (used by the Brown Boveri Companie) is described in detail. Expts. show that the

results usually do not agree within reasonable limits; this depends on the nature of the surface of the employed Cu. Results which agreed well were obtained by using strips of Cu sheet reduced in alc., washed in alc. and stored in benzene until use. The values of the tensile strength of the cotton-thread differ widely in the same oil and the detn. is of questionable value. Standard specifications for testing transformer oils suggested by the Union of Norw. Electricity Works are outlined and criticized. The Hepar sulfur test is not sufficiently sharp, oils contg. 0.015-0.016% S giving a negative test. It was proved that the S content depends on the refining method. Alkali-blue 6B is not a good indicator for detg. org. acids; thymolphthalein is better. In darker, used oils it is recommended to dil. with an equal amt. of a mixt. of equal parts of ether and alc. or a mixt. of benzene 2 and alc. 1 part. Then 2 sep. layers are obtained, the color change being observed in the upper alc. layer. When the tar no. is detd. the O should be dried and preheated to 55°. Cu as a catalyst in this oxidation may give unreliable results.

C. A. ROBAK

Laboratory distillation of petroleum. H. G. VESPER. *Ind. Eng. Chem.* **18**, 64-7 (1926).—A lab. method for evaluating the yields of refinery products of desired properties is presented. Data for crude petroleum from southern Cal. are presented. Since the control is based on temp. rather than on gravities, it is likely that with minor changes the method could be used with other crude petroleum. The crude is first topped (vapor temp. of 500° F) in any convenient still. The distillate is redistd. to det. gasoline and burning-oil, and the "tar" distd. *in vacuo* in order to det. lubricating distillates.

W. F. FARAGHER

Development of a standard Canadian laboratory distillation method for examination of oil shale. I, II. R. E. GILMORE AND A. A. SWINNERTON. *Can. Chem. Met.* **9**, 215-9, 235-9 (1925).—An av. good New Brunswick shale yielding around 30 Imp. gals. per ton was distd. in 5 different retorts: (1) The cross retort (sketch) in electrically heated Pb bath, capacity 3500 g. (2) Small field assay retort (sketch), capacity 350 g., with and without steam, heated by (a) gas burner, (b) elec. furnace. (3) Large field assay retort, capacity 1000 g., ditto, ditto. (4) Horizontal tube retort, capacity 1000 g., in gas muffle furnace. (5) Scotch tube (Bailey) method on 450 g. sample using long, open tube heated in gas furnace. All 5 app. are fully described, the methods of heating set forth and the results obtained tabulated. In each of the 5 methods the % of spent shale, oil, aq. distillate, gas and loss are recorded. The oil was fractionated, the B. t. u. of the gas detd., and a proximate analysis made of the spent shale. The small field retort (2) gave the highest oil yields (32 Imp. gals.); the lowest were given by (4) and (5) (28 and 29 Imp. gals., resp.). Steam did not materially affect the yield of oil in (2), but in (3) the yield increased by about 1 Imp. gal. per ton. In both cases steam increased the yield of heavy oils and decreased that of light oils, in each case by about 2 Imp. gals. per ton. More work should be done before a definite selection of a stand. lab. retort is made. G. and S., however, favor (3) tentatively. E. G. R. A.

Complementary notes on C. Căndea's paper on the oxidation of petroleum. GH. ALBESCU. *Bul. chim. soc. române de stiinte* **27**, 65-72 (1924); cf. Căndea, *C. A.* **18**, 3472.—Polemical, based mainly on the contention that C.'s method of detg. aromatic hydrocarbons is not a quant. method and consequently his results are of very doubtful value and contradictory.

A. PAPINEAU-COUTURE

Latent heats of vaporization of distillates from paraffin-base petroleum. E. H. LESLIE, J. C. GONIESSE, T. W. LEGATSKI AND L. H. JAGROWSKI. *Ind. Eng. Chem.* **18**, 45-6 (1926).—Close fractions from Cabin Creek, W. Va., crude were used. The distn. was effected by an electrically heated resistor; precautions against refluxing were taken. Heat loss from the vacuum-jacketed flask was detd. by distg. liquids of known latent heats that covered the temp. range 80.8-193.1°. For the fractions b. up to 220°, the accuracy of the values is thought to be ± 2 cal. per g. Tables and curves are presented. The exptl. values are lower than published data calcd. by using Trouton's rule.

W. F. FARAGHER

Evaporation losses of gasoline in the refinery. LUDWIG SCHMIDT. *Bur. Mines, Repts. of Investigations* No. **2721**, 16 pp. (1925).—Results are shown of the detn. of evapn. losses in a typical Mid-Continent refinery at different stages of refining. They were as follows: (1) run-down tanks, 1.8%; (2) treating (agitators), 0.5%; (3) filling tank cars, 0.5%; (4) storage, 2.5%; (5) miscellaneous handling, 1.0%. Several curves and tables are shown.

W. H. BOYNTON

Separation and purification of naphthenic acids. L. GURVICH. *Brennstoff-Chem.* **6**, 322-3 (1925).—The old method of sepn. of the acids from their Na soaps with H_2SO_4 leads to formation of worthless Na_2SO_4 . If SO_2 is substituted for H_2SO_4 , the resulting Na_2SO_3 may be readily causticized with lime with recovery of Na as NaOH. Sepn.

takes place easily at 70° with 60% of SO_3 theoretically required. This leaves 40% of the soap still undecomposed which is not a disadvantage in soap mfg. Complete decompn. of the soaps requires a very large (230%) excess of SO_3 . The usual method for purification of petroleum oils based on simple washing with concd. H_2SO_4 will not apply to naphthenic acids since a homogeneous mixt. from which there is no sepn. of tar contg. acid is formed. If 12% fuming H_2SO_4 is added to the raw acid, followed after the reactions are complete by 20% water, satisfactory sepn. of acid tars takes place. J. D. DAVIS

Recovery of sodium plumbite in the oil industry. A. KINSM. *Chem. Met. Eng.* 32, 873-4 (1925).—A patented process and a plant (U. S. patent No. 1,525,301 issued to K.) that recovers more than 99% of the lead used in the sweetening of gasoline and 75-80% of the caustic soda are described briefly. W. F. FARAGHER

Lubricants and lubrication. JAMES DUGUID. *Mech. Eng.* 47, 887-94 (1925).—An address, covering the general subject in a not highly technical way. W. F. F.

Chemical composition of the tar obtained by distillation of coal from Lupeni (Roumania) (GEORGEACOPOL) 21. Equilibrium boiling points (WHATMOUGH) 21. The fuel oil situation as it affects gas company operation in California (BERRY, BROWN) 21. Naphthenic acids (TANAKA, NAGAI) 10. Still for crude petroleum (Brit. pat. 233,419) 21. Oil filter (U. S. pat. 1,568,796) 1. Apparatus for neutralizing and bleaching oils under a vacuum (Brit. pat. 233,345) 1.

DUMESNY AND NOYER: *L'industrie chimique des bois. Leurs dérivés et extraits industriels. Pt. I: La distillation du bois. Pt. II: Fabrication d'extraits divers.* Paris: Gauthier-Villars et Cie. 432 pp. Fr. 25.

LILLEY, ERNEST RAYMOND: *The Oil Industry.* New York: D. Van Nostrand Co. 558 pp. \$6.

Purifying oils. SHARPLES SPECIALTY Co. Brit. 233,334, April 29, 1924. Oil contg. sludge or sludge-forming or emulsion-forming substances (e. g., used lubricating oil) are treated with H_2O and subjected to centrifugal sepn.

Purifying oils. AKTIEBOLAGET SEPARATOR. Swed. 59,250, Aug. 15, 1925. The oil is mixed with water and the mixt. is stirred and passed through a centrifuge by which the water and the major part of the impurities are sepd. and then through a filter removing the remaining impurities.

Refining hydrocarbon oils. J. C. MORRELL. U. S. 1,568,904, Jan. 5. The oil (e. g., cracked distillate) is separately treated with H_2SO_4 and with NaOH contg. PhO , and, subsequently, with SO_2 .

Distilling petroleum. A. R. EARL and T. W. REEVES. U. S. 1,567,429, Dec. 29. Oil is heated under pressure by use of steam, released from pressure and passed into an expansion zone where part of the oil vaporizes. Vapors thus formed are conducted away and fractionally condensed. Unvaporized oil is withdrawn and further heated without permitting vaporization and the heated oil is passed into an expansion zone maintained at subatm. pressure where vaporization of light products is permitted and the vapors of these are withdrawn and condensed. The unvaporized oil is withdrawn from this expansion zone and heated by direct contact with superheated steam while maintained under sufficient pressure to prevent vaporization of the oil. The pressure of the oil is then released and the heated oil is passed into an expansion zone under subatm. pressure to form additional vapors which are condensed and recovered.

Gasoline. W. F. DOWNS. U. S. 1,568,812, Jan. 5. Vapors from hydrocarbon oils having a b. p. below 260°, of varying compn. with respect to H:C ratio and condition of satn., are condensed in the presence of a porous mass comprising metallic chlorides such as AlCl_3 , SiO_2 and graphite and the condensate is continuously withdrawn. U. S. 1,568,813 specifies purifying hydrocarbon oils by filtering them through a heated filter bed contg. chlorides such as AlCl_3 maintained below the b. p. of the oil and also below the vaporizing point of the chloride.

Cracking hydrocarbon oils. F. B. KOONTZ. U. S. 1,567,062, Dec. 29. A stream of oil is conducted through a cracking zone heated to cracking temp. The highly heated oil is discharged into a sepg. chamber where carbonaceous residue is deposited and where the temp. is sufficiently high to effect evapn. of liquid of low b. p. from the residue. The carbonaceous residue is removed from the sepg. chamber as it accumulates and is discharged from the app. and vapors from the sepg. chamber are led upwardly at such a low velocity as to permit pptn. of carbonaceous material from the rising vapors. The relatively clean vapors are subjected to reflux condensing to condense about 70%

of the vapors and the remaining vapors are separately condensed. Heated fresh charging stock is supplied in a proportion of less than one-third the quantity of the reflux condensate and this mixt. is pumped to the cracking zone.

Cracking and hydrogenating oils, etc. G. W. WALLACE. Brit. 233,395, Feb. 1, 1924. Shale oil, petroleum oil, naphthalene oils, anthracene oils or the like are atomized (optionally with steam or hydrogenating gases) in proximity to a flame in the upper part of the reaction chamber which may be filled with refractory material (optionally treated with a catalyst). The materials pass downwardly through the refractory filling and cracking or hydrogenation may be effected either under increased or reduced pressure.

Separating condensable hydrocarbon vapors from gases. J. C. SWAN. U. S. 1,568,028, Dec. 29. The gas is passed through a column of Hg or other liquid the temp. of which is maintained below the condensing temp. of the component to be sepd., *e. g.*, condensable hydrocarbons from natural gas, by circulating a refrigerating liquid through a refrigerating plant and in heat-exchange relation to both the interior and exterior of the column.

Distilling and blending hydrocarbons. D. L. NEWTON. U. S. 1,567,457-8, Dec. 29. An absorbing medium contg. hydrocarbons absorbed from casinghead gas is subjected to a partial distn. and conducted through a series of chambers successively in one direction. Steam is mixed with the distd. vapors and the resulting mixt. is conducted under pressure through the chambers in the opposite direction in an app. somewhat resembling a usual column still. Distd. hydrocarbons are blended to form a com. "stabilized" gasoline.

"Converting" hydrocarbon oils. J. H. ADAMS. U. S. 1,568,016, Dec. 29. Oil is subjected to direct contact with an elec. resistor immersed in the oil and heated electrically to a cracking temp. and is maintained under superatm. pressure during the treatment.

Recovering values from acid sludge. H. T. BENNETT, G. B. MURPHY and L. G. STORY. U. S. 1,568,261, Jan. 5. Acid sludge contg. asphalt-like substances, such as is obtained by treating petroleum oils with H_2SO_4 , is treated with a solvent contg. alc. and C_6H_6 or a similar coal tar deriv. After sepg. the soln. thus formed and distg. the solvent, a product remains which is of asphaltic character, adapted for use as a *paint*.

Regulating gas pressures at oil wells. R. CONRADER. U. S. 1,567,183, Dec. 29. A pressure is maintained on the well, sufficient gas for local operation is draw off and the excess is delivered to a sep. low pressure line.

Oil still. J. PRIMROSE. U. S. 1,568,182, Jan. 5. Oil to be cracked flows through a bank of heated tubes. Cf. C. A. 20, 501.

Separator for gas, oil, water and sand. G. A. WILSON and R. W. EDENS. U. S. 1,567,313, Dec. 29.

Apparatus for cracking hydrocarbon oils. C. P. DURBS. U. S. 1,568,400, Jan. 5. The app. comprises an elongated heating coil, an enlarged reaction chamber, dephlegmator, connections for refluxing, etc.

Apparatus for distilling and cracking hydrocarbon oils. F. C. VAN DE WATER and F. R. SUNDERMAN. U. S. 1,567,212, Dec. 29. Vapors from a drum still are passed through a cracking tube located beneath the still and which is protected from undue heating by a surrounding air jacket and a sheath of protective material.

Apparatus for separating and extracting mineral oils from oily sand, bitumen from oily chalk, oily slate, coal, etc., by the use of hot water. H. PRELLER. U. S. 1,567,983, Dec. 29.

Filter for reclaiming crank-case oil and other mineral oils and animal fats. J. V. APABLASA. U. S. 1,567,989, Dec. 29.

Steam-heated still for evaporative distillation of petroleum. D. L. NEWTON. U. S. 1,567,455, Dec. 29.

Absorption tower adapted for recovering gasoline from natural gas. D. L. NEWTON. U. S. 1,567,456, Dec. 29.

Lubricant for use as a "cup grease." A. B. HUTTON. U. S. 1,568,606, Jan. 5. Petroleum jelly 8, white lead 4, graphite 0.5, S 0.5, linseed oil 1 and tallow 2 parts.

Filter for lubricating oil, etc. J. V. APABLASA. U. S. 1,567,990, Dec. 29.

Hardened asphalt products. N. A. F. LIDVALL and P. A. WESSBLAD. Swed. 59,754, Oct. 27, 1925. Genuine or artificial asphalt is mixed with sulfur and a soln. of raw or vulcanized rubber in such proportions that the amt. of asphalt is at least 3 times that of rubber. The solvent is evapd. and the mixt. is hardened or vulcanized by heating.

Bituminous emulsions. L. KIRSCHBRAUN. U. S. 1,567,061, Dec. 29. A non-

adhesive emulsion is prepd. from adhesive bituminous material, H_2O , an emulsifying agent such as colloidal clay and a flocculating agent, *e. g.*, $Al_2(SO_4)_3$ or Na acid phosphate.

Bituminous emulsions. L. S. VAN WESTRUM. Brit. 233,371, Nov. 8, 1923. Emulsions which may be used cold as binders for paving materials, etc., and also for waterproofing are formed by the sapon. by NaOH, KOH or other alkali of asphalt, tar or mixts. contg. them together with linseed or other drying oils. Rapeseed oil or other non-drying oil may be added to retard the drying of the product.

Bituminous emulsions. H. A. MACKAY. Brit. 233,430, Feb. 8, 1924. Emulsions suitable for use in paving, manuf. of briquets or for waterproofing are prepd. by mixing Mexican asphalt or tar or other naturally liquid or melted bituminous material with a small proportion of an emulsifying agent comprising cholesterol and adding hot H_2O . Oleic acid and NaOH may be used as emulsifying materials. Cf. C. A. 20, 283.

Apparatus for destructive distillation of bituminous materials. PATENTAKTIEBOLAGET GROENDAL-RAMÉN. Swed. 58,777, May 27, 1925. An inclined rotary furnace with refractory lining contains several longitudinal channels open at either end. These channels contain the material to be treated; they operate as sep. retorts and are built in such a way that the hot distn. products pass on all sides of them and at the same time hot indifferent gas passes through the channels.

Pure betulinal from birch-bark. J. R. KOEHLER. Swed. 59,290, Aug. 19, 1925. Betulinol, together with certain impurities, is extd. by means of a solvent in which the org. bases occurring in the bark are insol. The soln. is treated with an org. base or a salt of such base and a weak acid, by which treatment the impurities are converted into compds. insol. or difficultly sol. Pure betulinal is recovered from the remaining soln. by crystn. or evapn.

Jacketed retort for carbonizing wood, etc. R. MALBAY. Brit. 233,335, May 5, 1924.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

The thermal decomposition of cellulose under hydrogenation conditions. A. R. BOWEN, H. G. SHATWELL AND A. W. NASH. *J. Soc. Chem. Ind.* 44, 507-11T, 526T (1925).—Samples of cotton cellulose were treated with H_2 under pressure of about 40 atm. at temps. from 420 to 440° in 2 and 3 successive 4-hr. periods. The runs were made without catalysts, and also in the presence of NiO, pptd. on the fibers as the oxalate, and V_2O_5 and $Fe(VO_3)_3$, impregnated in the fibers as $Fe(VO_3)_3$ and NH_4VO_3 . Without catalysts the cellulose absorbed no H_2 , showing no hydrogenation had occurred. The residue consisted mainly of a coke-like residue, H_2O and CO_2 , with only small quantities of light oil, $CHCl_3$ -sol. tar and gases. With NiO considerable H_2 was absorbed, hydrogenation having taken place. An increase in amts. of light oil and $CHCl_3$ -sol. tar resulted. With V_2O_5 and $Fe(VO_3)_3$ as catalysts practically no hydrogenation occurred. Comparison of oils obtained from cellulose and 4 British coals, after treatment with H_2 , showed them very similar in properties and, in a lesser degree, in chem. compn. The evidence supports the theory of coal formation from cellulose. Destructive distn. of cellulose with and without the catalysts showed the catalysts, especially NiO, exerted considerable influence on carbonization as by their use an increase in evolved gas and coke residue resulted.

W. H. SWANSON

Depolymerization or dispersion of cellulose? R. O. HERZOG AND D. KRÜGER. *Naturwissenschaften* 13, 1040-2(1925).—Expts. are discussed bearing on the subject, whether the constituent parts of cellulose are held together by chem. valence or by cohesive forces. Cellulose crystals can be transformed into cryst. nitro and Ac derivs.; of these colloidal solns. can be made contg. per particle as many cellulose building stones as the original cellulose crystal. From diffusion expts. it was found that acetylcellulose disperses in acetone when the diam. of the particles is less than 20μ , in $AcOEt$ 5μ , in epichlorohydrin 35μ . Cellulose soaked in 17% NaOH, squeezed out and exposed to air, showed a continually decreasing particle diam.; if, however, the cellulose was left in the alkali the diam. at first fell rapidly, then increased slightly to a const. value (in 2 hrs.) of about 8.5μ . This may indicate a chemically sp. action of the O_2 . No definite conclusions are offered.

B. J. C. VAN DER HORVEN

Remarks on Heuser's paper on the depolymerization of cellulose. KURT HESS. *Z. Elektrochem.* 31, 613-4(1925); cf. C. A. 20, 110.—Since Hess has shown that Me

cellulose such as that prep'd. by Heuser is a mixt. of several products (*C. A.* **18**, 1384), Heuser is not justified in estg. the degree of depolymerization by detg. the mol. wt. of the methylated product. Hess points out that conditions are further complicated by the increase in mol. wt. of methylated cellulose with time, but states that he will later publish data from purified material whose mol. wt. is const. ROSALIE M. COBB

Cellulose. XVI. Crystallized acetylcelluloses. 2. KURT HESS, GUIDO SCHULTZE AND ERNST MESSMER. *Ann.* **444**, 266 87(1925); cf. *C. A.* **19**, 3161.—Crude cellulose acetate was prep'd. by Ost's modification of the German pat. 252,706 (*C. A.* **13**, 2760), extd. with and recovered from Me_2CO and purified according to the Biehengrum method (German pat. 254,385) by heating for 2 hrs. at 65–70° with C_6H_6 - EtOH (1:1), filtering the hot soln. and allowing the filtrates to cool gradually. The results of 40 such fractional pptns. have been tabulated, an individual sample of cellulose acetate being used. The initial treatment of 50 g. of the crude (Me_2CO sol.) acetate mixt., which was heated with 300 cc. of solvents at 65°, filtered and cooled to 30°, yielded 1.55 g. of ppt. The residue remaining insol. at 65° was then reheated with a fresh EtOH - C_6H_6 mixt. and the fractionation continued. The 20th prepn. of cellulose acetate obtained in several parallel series of such purifications was compared and subjected to further study. In general these prepn.s, which approach the *diacetate*, but which may not be homogeneous, are distinctly cryst. $[\alpha]_D^{25}$ ($\text{EtOH}-\text{CHCl}_3$) -1.79° to -7.89° , yielding 51.6–53.9% AcOH and readily convertible, on reacylation in the presence of ZnCl_2 , into the pure triacetate (yielding 62.2–62.8% AcOH , $[\alpha]_D$ CHCl_3 -19.8° to -19.95°). The more sol. portions of the 1st 15 fractionations (*i. e.*, those sol. at 65–70°, but sepg. at 30–45°) were combined and recrystd. from C_6H_6 alc. (I). A similar treatment was accorded the combined sol. portions of fractions 21–40 (II). The most insol. portion (III) (*i. e.*, the material crystg. from alc.- C_6H_6 at 50° after the 40th fractional pptn.) was also isolated and compared with the original Me_2CO -sol. acetate mixt. (IV). The % AcOH , $[\alpha]_D^{17}$ in CHCl_3 alc., and $[\alpha]_D^{17}$ in $\text{C}_6\text{H}_5\text{N}$ of I, II, III, and IV are, resp.: 52.78, 52.11, 52.68, and 53.05; -1.03° , -1.01° , -3.41° , and -5.44° ; -22.03° , -21.42° , -18.93° , -23.82° . The η_{inh} of I, II, III and IV are, resp., 0.0232, 0.0323, 0.344, 0.0269. Sapon. of I, II and III with NaOH in MeOH , followed by measurements of $[\alpha]_D$ in standardized cuprammonium solns., showed remarkable agreement with the $[\alpha]_D$ of pure cellulose in cuprammonium solns. of identical concns. These data point to the fact that the ultimate cellulose unit remains intact after sapon. of the cryst. acetates. The solubilities of I, II and III in 2 *N* NaOH show differences, I being the most sol. The thickness of matting (*Dichte der Verfilzung*) of the different cryst. prepn.s. appears responsible for the differences in phys. properties. Systematic fractionation of 50 g. of IV was also effected by repeated extn. with successive 500 cc. portions of CHCl_3 in a Clausnitzer extn. app.; 13 such extns. yielded fractions showing similar properties (51.5–53.0% AcOH , $[\alpha]_D^{18}$ (in CHCl_3 -alc.) -3.2° to -6.2°). These prepn.s. on sapon. invariably gave rise to cellulose (as indicated by $[\alpha]_D$ of the cuprammonium solns.). Even after 13 extns., however, nearly 40 g. of material remained insol. in CHCl_3 ($[\alpha]_D^{18}$ in CHCl_3 -alc. -4.53° ; yielding 50.11% AcOH). The conditions for crystn. of the acetates depend on the presence or absence of contaminating sugars (formed as degradation products), on the concns. of the solns., the rate of cooling, and the nature of the solvents. Normally 6 pptns. from C_6H_6 -alc. are required before prepn.s. show definite double refraction. However, the conditions of crystn. are not sharply defined. In one case a distinctly cryst. ppt. on attempted recrystn. from 50 parts of a C_6H_6 -alc. mixt. gave an amorphous ppt. Rapid cooling inhibits crystn., although ppts. obtained in this way may crystallize on standing. Cryst. products may also be obtained from AcOEt and (after long standing) from CHCl_3 . Photomicrographs of acetate crystals are given. The crystals show the remarkable property of swelling (inhibition) prior to soln. Pure cellulose triacetate may also be crystd. but details of its prepn. are not given. **XVII. Characterization of preparations of cellulose.** KURT HESS, ERNST MESSMER AND NOAH IJUBITSCH. *Ibid* 287–327.—Since the $[\alpha]_D$ of cellulose cuprammonium solns. depends directly on the concns. of Cu and cellulose in soln. and on the formation of a complex of high $[\alpha]_D$, the detn. of the rotation curves of such solns. offers a means of showing the similarity or dissimilarity of celluloses of different botanical origin or obtained in different industrial operations. The cellulose-cuprammonium rotation curve is markedly different from the rotation curves of cuprammonium solns. of the amyloses, lichenin, acetone-glucose and methylcellulose, and is presumably quite characteristic (cf. *C. A.* **18**, 1384) for cellulose solns. H., M. and L. find that carefully purified spruce wood cellulose, Egyptian and American

cotton, and ramie cellulose give identical rotation curves in cuprammonium and therefore contain the identical cellulose unit. This is also true for mercerized and unmercerized cotton linters, initially purified by E. Schmidt's ClO_2 method. Apparently mercerized cellulose is less readily sol. in cuprammonium than is unmercerized cellulose and these solns. show a higher viscosity than do similar solns. of unmercerized material. (This is contrary to the commonly accepted point of view—ABSTR.). Cuprammonium solns. of "cuprammonium silk," and of the alkali-sol. and alkali-insol. fractions of such silk are practically identical with those of pure cotton. The artificial fiber is, therefore, physically non-homogeneous with the cellulose units intact. Rotation curves of viscose silk solns. show the same general shape as those of cellulose but some of the $[\alpha]$ values are 2.5% lower. These slight deviations are presumably due to small quantities of impurities. The curves of "hydro-cellulose" and "celloextrin" in cuprammonium also suggest those of pure cellulose, although they show marked deviation from the norm, which might be expected from cellulose mixed with degradation or conversion products (like isocellobiose). These deviations may be as high as 7% with hydrocellulose, and 21% with the celloextrins. Despite these deviations, however, the presence of the typical cellulose unit is not obscured and wide-spread degradation is not indicated. Rotation curves and complete tabulated data are given. Various celluloses in cuprammonium soln., which show identical rotation curves, may show markedly different viscosities. Cuprammonium solns. free from cellulose contg. 10 N NH_3 (and 20 millimols NaOH and 5 millimols $\text{Cu}(\text{OH})_2$ in every 100 cc.) showed η^{20} 0.0129. In similar solns. American cotton gave η^{20} 0.798; Egyptian cotton 0.078; another unmercerized cotton 0.0328, this identical sample (after mercerization) 0.0361, wood cellulose 0.496 and ramie fiber 0.0583.

LOUIS E. WISE

Stability of nitrocellulose. J. DUCLAUX. *Rev. gén. colloïdes* 3, 257-63(1925) — The samples used were all sol. in Et_2O -alc. They were made homogeneous by dissolving in $(\text{CH}_3)_2\text{CO}$, pptn. by H_2O , redissolving in various solvents, flowing on glass plates and drying under various conditions. Stability tests were made by heating the film at 100 or 110°, weighing to det. loss of wt., dissolving in $(\text{CH}_3)_2\text{CO}$ to a 2% concn. and detg. viscosity at 25°. A previous study (*C. A.* 15, 3393) showed that concordant results were obtained both by loss of wt. and viscosity reduction detns. The latter is preferable because of elimination of errors from incomplete evapn. of solvent, hygroscopic H_2O and slow diffusion of products of decompn. through the film if thick. It was found that stability was not a function of chem. compn. alone because films of various thickness made from the same soln. of a rather unstable nitrocellulose gave widely differing losses in wt. A given nitrocellulose gives films of varying d. when deposited from different solvents, proving differences in internal structure. A mixt. of Et_2O -alc. as solvent does not give a const. state of film because of changes in solvent during evapn., but when a single solvent is used such as isobutyl formate or mesityl oxide this is not the case and here films are obtained of the same stability irrespective of thickness. Equal stability was obtained by using a mixt. of high- and low-boiling solvents because the former remain after all the latter have gone. While stability depends largely upon chem. compn. the phys. state can alter stability in the ratio of 1:6. The variations in phys. structure are accompanied by changes in d. E. M. SYMMES

Georgia and Alabama clays as fillers. W. M. WEIGEL. *Bur. of Mines, Tech. Paper* 343, 34 pp.(1925); cf. *C. A.* 19, 1792.—Tests of clays from the Alabama and Georgia districts showed practically all of a large no. of samples to be suitable as fillers for paper when compared with the English and American clays commonly used. The properties considered in these tests were grit, whiteness or color, and retention. Analyses and descriptions of tests for use as rubber and paint fillers and oil cloth covering are also included.

W. H. SWANSON

Jelutong or pontianac rubber resin as a sizing agent. J. S. REMINGTON. *Ind. Chemist* 1, 467-8(1925).—Jelutong contains from 35.75 to 49% of resin in which there are 2 constituents, α and β . The probable formula for both is $\text{C}_{20}\text{H}_{40}\text{OH}$. R. gives many of the properties of both constituents. Trials to use them as a size for paper were unsuccessful. Mixing the resin with American rosin as follows gave a usable size: American rosin 1000, Jelutong resin 1000, caustic soda (80° Tw.) 700 lbs., water as much as possible, with 100 parts of pulp to 4 parts of the total resins. E. G. R. A.

Present status of lignine research. C. KELLIN. *Svensk Kem. Tids.* 37, 209-19 (1925).—A review to which is appended a bibliography of 138 titles referred to in the text and 52 additional titles subsequent to 1923.

A. R. ROSE

Plasticity in relation to cellulose and cellulose derivatives (SHEPPARD. CARVER) 2.

Sulfite cellulose. A. PEERTZ. Brit. 233,318, April 30, 1924. In producing cellulose by the bisulfite process, requisite reduction of pressure, whenever the desired maximum pressure is exceeded, is effected by discharging a portion of the liquor from the boiler, the upper valve being used only for discharging the air present. A saving in high-pressure steam is thus effected.

Cellulose carboxylates. SOC. DE STEARINERIE ET SAVONNERIE DE LYON and P. BERTHON. Brit. 233,263, Nov. 28, 1924. The process for the prepn. of cellulose esters of the higher fatty acids described in Brit. 201,510 (*C. A.* 18, 469) is modified by using as a diluent, during the esterification of the hydrocellulose, toluene, xylene or homologs.

Chlorinating sulfite liquor. A. SCHMIDT. U. S. 1,567,395, Dec. 29. Sulfite liquor is first treated with Cl gas and the resulting material is then further treated with nascent Cl, formed, *e. g.*, by use of chlorate and HCl. The product thus obtained is suitable for use in *tanning or resin substitutes*.

Recovering lye from disintegrated cellulosic materials. G. MOSEBACH. U. S. 1,567,668, Dec. 29. Straw or a similar substance is heated to about 70° with undil. lye while being stirred, the lye is squeezed out, and the compressed material is treated with hot H₂O at about 70°, stirred, and the hot H₂O contg. about 10% of the lye used is squeezed out and re-used for the prepn. of fresh lye.

Apparatus for hydrating or beating cellulosic fibers. H. JACKSON, LTD. and H. JACKSON. Brit. 233,501, April 10, 1924.

Nitrocellulose emulsions. T. WHITELSEY. Brit. 233,367, Nov. 6, 1922. A colloidal soln. of nitrocellulose in AmOAc or other solvent is emulsified with H₂O or other liquid which is not a solvent of the nitrocellulose and which may contain Na oleate or gelatin or other emulsifying agent.

Recovering valuable substances from waste gas from soda furnaces in sulfate cellulose factories. O. NORDSTROEM and A. MOERCH. Swed. 59,691, Oct. 13, 1925. The gases are filtered by passing through a drying shaft filled with raw chips which take up solid and condensable substances from the gas and at the same time are dried by the hot gases. The chips are afterwards charged into the boilers without removal of the absorbed substances.

Evaporating sulfite cellulose waste liquor. H. A. E. NILSSON. Swed. 58,778, May 27, 1925. The vapors which are compressed and used for heating purposes in the app. are treated with absorbents before they are compressed in order to remove the acid components and so reduce their corroding effect on the metallic parts of the compressor and app.

Alcohol from sulfite cellulose waste liquor. J. H. WALLIN. Swed. 58,822, June 3, 1925. The waste liquor is neutralized, in full or in part, by means of lime previously used for dehydrating the spirit. The alc. retained in the lime is not removed before the lime is used for the neutralization.

Charging cellulose boilers. P. A. FRESK. Swed. 59,300, Aug. 19, 1925. The chips are introduced into the boiler by a current of air assisted by a vacuum produced in the boiler.

Combining rubber with paper pulp. E. HOPKINSON and E. P. ROSE. U. S. 1,567,646, Dec. 29. Pulp, *e. g.*, kraft paper pulp, is mixed with rubber latex, and the mixt. is agglomerated, further mixed and the rubber is coagulated. The product is adapted for making continuous sheets.

Ornamenting surfaces of paper, cardboard, etc. M. A. TURNER. U. S. 1,568,108, Jan. 5. A coating of corn starch mixed with sufficient liquid to form a viscous mixt. is applied in varying thickness, followed by the application of a coloring pigment while the first coating is still in viscous condition. When dried the coating is substantially flat but presents an embossed appearance.

Dyeing paper pulp. A. G. TEMPERLEY, J. THOMAS and SCOTTISH DYES, LTD. Brit. 233,382, Dec. 12, 1923. Pulp is dyed with 1-amino-2-methyl-, 1-methylamino-, 1,4-diamino-, 1-amino-4-hydroxy-, 1-chloro-5-aminoanthraquinone or other aminoanthraquinone compd. of like character. Resin size, alum and china clay may be added to the pulp as usual.

Paper fibers easily sizeable. CENTRALGRUPPENS EMISSIONSAKTIEBOLAG. Swed. 59,580, Oct. 7, 1925. The fibers are washed and treated with free alkali or an alk. soln. of such a concn. that those substances which are harmful to the size are extd. without dissolving any resin.

Paper machine. W. LJUNGSTROEM. Swed. 59,579, Oct. 7, 1925. Mech. features. Cf. *C. A.* 19, 1497.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

Analysis of explosives. A new apparatus for the test at 135°. PEDRO T. VIGNAU AND JERONIMO ANGLI. *Rev. facultad ciencias* 3, No. 2, 51-3(1925)—A closed bath 20 X 80 X 15 cm. is provided with 2 Liebig reflux condensers and 21 tubes arranged in 1 row for the samples and the thermometer. The water from the condensers enters a small tank above the app. which affords protection from fire. All parts are made of Cu.

MARY JACOBSEN

The Waltham Abbey test in the testing of cordite powders. PEDRO T. VIGNAU AND ROGELIO T. BABUGLIA. *Rev. facultad ciencias* 3, No. 2, 47-50(1925).—Without proper precautions the method of Waltham Abbey may give variations as high as 50 hrs. Satisfactory results were obtained in thousands of samples when scrupulous cleanliness, abs. absence of moisture and uniform heating were observed and the powder was ground without development of heat. The Ag coat on the inside of the app. is superfluous and interferes with the proper inspection of the cleanliness and dryness of the app.

MARY JACOBSEN

Rifle and artillery guncotton from "Letea" brand wood cellulose. GH. PANDELE. *Bul. chim. soc. române de stiinta* 27, 79 128(1924) (in Roumanian); reprint 60 pp., 19 25, [in French]—Bleached sulfite pulp from the Letea mill (Roumania), having ash 0.42, fats and waxes 0.22%, Cl trace, when in the form of a very light (13 g. per sq. m.), porous, creped sheet (such as are used in prepg. surgical dressings), is nitrated more rapidly than cotton, but the powders obtained have a lower N content and a higher soly. than cotton powders and retain much more acid. When nitrated with an acid of suitable compn. (the exact compn. is a state secret), with about the same amt. of acid and the same temp. as for cotton, Letea sulfite gives rifle powder with 13 10% N and 20 50% soly., and an artillery powder with 12.75% N and 89% soly. They can be stabilized in about 25 hrs., as compared with 60 hrs. for cotton powders, and with all stability tests give better results than the cotton powders. The powders prepd. from the sulfite are not mixts. of different nitrocelluloses more or less highly nitrated, as are the cotton powders, and consequently they are more homogeneous and stable than the latter, and they give uniform ballistic results without any variation in the pressure. On treatment with EtOH there is no loss of nitrocellulose, and only about half as much EtOH and Et₂O is required to work up the powder as for cotton powders.

A. PAPINEAU-COUTURE

Mixtures of explosive nitrates. Reply to chemists of the Bureau of Mines of Pittsburgh. MICHELE GIUA. *Gazz. Chim. ital.* 55, 422-4(1925).—G. again calls the attention of Taylor and Rinkenbach (*C. A.* 17, 879, 880, 3100) and of Bell (*C. A.* 17, 3125) to his work on the system TNT-tetryl (*C. A.* 9, 2089, 3362; 10, 1175, 1176; 11, 1547).

E. J. WITZEMANN

Explosivity of brown-coal dust. WEISS. *Braunkohle* 24, 782-3(1925); cf. *C. A.* 19, 2565.—Observations on the gain in weight (by oxidation) of dry coal samples confirm those on the effect of moisture in reducing the explosivity of brown-coal dust.

WM. B. PLUMMER

BEYERSDORFER, PAUL: **Staub-Explosionen.** Dresden and Leipzig: Theodor Steinkopff. 125 pp. Price, paper M. 5.50; bound, M. 7.

PASCAL, P.: **Explosifs, poudres, gaz de combat.** Paris: Librairie Scientifique J. Hermann. 296 pp. Fr. 35. Reviewed in *Chemistry and Industry* 44, 1132(1925).

Explosive. T. L. DAVIS. U. S. 1,568,502, Jan. 5. Hexanitrocarbanilide is used in "booster" charges or otherwise as an explosive.

Nitrate conglomerates for use in explosives. W. M. DEHN. U. S. 1,568,324, Jan. 5. Conglomerates of NH₄NO₃ and NaNO₃ are formed by heating the salts to form sludges and then rapidly cooling them.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Advances in the chemistry of dyes in 1924. FRITZ MAYER. *Chem.-Ztg.* 49, 949-51, 970-2, 985-7, 1001-3, 1025-6, 1029-30(1925).

E. J. C.

Surveys of recent progress in the dyeing, printing and allied industries. I. Tex-

tile fibers. **Artificial silk.** J. HUEBNER. *J. Soc. Dyers Colourists* **41**, 387-401 (1925).—In this review an attempt has been made to collect all the work, including patents, which has been published on the above-named subject during the period 1914-1925. About 350 papers are noted with abstracts averaging 5 or 6 lines each. L. W. RIGGS

Dyes and photochemistry. I. SEDLACZEK. *Phot. Ind.* **1925**, 950.—In a general discussion of the principles of dyeing and the textile industry various terms such as substantive dye, indirect dye, pigment dye, mordant, lake, etc., are explained. Examples of mordants for acid and for basic dyes are given. M. L. DUNDON

Importance of the synthetic dyestuffs industry. JOSEPH TURNER. *J. Soc. Dyers Colourists* **41**, 384-7 (1925).—An address.. L. W. RIGGS

How dyes are made. MAX MUSPRATT. *J. Soc. Dyers Colourists* **41**, 401-3 (1925).—An address. L. W. RIGGS

Comparative study of azo dyes made with H acid and acetyl-H acid. W. W. LEWERS AND ALEXANDER LOWY. *Ind. Eng. Chem.* **17**, 1289-90 (1925).—A series of dyes was prepd. from 33 diazo compds.; as the coupling component were used H acid and acetyl-H acid. The latter series was hypsochromic, and in general faster to the action of acids and alkalis. T. S. CARSWELL

A microscopic method for identifying Naphthol AS dyeings. LUDWIG LÖCHNER. *Textilber.* **6**, 914-6 (1925).—Dyestuffs formed on the fiber by coupling with Naphthol AS may be extd. with HIOAc and crystd. on an object glass. As a variety of crystal forms are so obtained, it seems that by considering the color and crystal form, a systematic method of identifying the original substances can be devised. Some typical photomicrographs are exhibited. E. R. CLARK

Lime in the treatment of dye and textile wastes. F. D. SNELL. *Rock Products* **28**, No. 18, 61-2 (1925).—Description of acid neutralization and coagulation of dye wastes by Fe or Al sulfate and lime. High Ca lime is preferable to magnesian lime. RAYMOND WILSON

New possibilities in dyeing with indigosols. GUSTAV FRIEDLANDER. *Textilber.* **6**, 916-7 (1925).—The properties of the sol vat colors recently introduced suggest a number of new possibilities in dyeing. Much better fastness to soap and crocking as compared with the ordinary vat is obtained. Combinations with the fast direct colors give a variety of shades of great fastness, and with aniline blacks, a pleasing depth is obtained. Metanitrailine Orange and the like can be used together with indigosols and the possibilities of new discharge styles are great. By impregnating fabrics with a mixt. of Indigosol O, Na₂S₂O₄, and NH₄ClO₄, and exposing partially to light, novel photographic prints may be obtained. E. R. CLARK

Report of Research Committee. I. A. OLNEY. *Proc. Am. Assoc. Textile Chem. Colorists* **1925**, 224-5; *Am. Dyestuff Rept.* **14**, 852-3.—A brief general review of the work of the year is given. The reports of the various sub-committees were followed by discussion. **Report of Sub-Committee on Light Fastness.** WM. H. CADY. *Ibid.* **1925**, 6, 853-4; cf. *C. A.* **19**, 1057.—Tests with sunlight led to the following conclusions: (1) The angle of exposure is important when total fading is considered, the fading being greatest with horizontal exposure and less in order with 45 and vertical exposures. Angle of exposure has little effect on relative fading. (2) Covering samples with glass influences the fading but not always in the same way. (3) The effect of free circulation of air or the lack of it cannot be ignored. (4) Continuous exposure produces different fading from exposure only to the sun when it is high and free from clouds. (5) Direct sunlight has a different effect from "skylight" without sun. (6) Exposures made in different localities show little variation in relative fading. (7) Exposures made at the same location at different seasons of the year show little variation so far as these tests have been carried; the work, however, is not completed. **Report of Sub-Committee on Standard Tests for Fastness to Washing.** W. M. SCOTT. *Ibid.* **1925**, 6, 855-8.—The 4 tests used were made with 1% soap solns. acting for 10 min. under the following conditions: (1) boiling, (2) 71, (3) 49, (4) 29. According to the results of these tests goods were divided into Class 1—no appreciable change after test (1), Class 2—changed by test (1) but not by test (2), Class 3—not changed by test (3), Class 4—not changed by test (4), and Class 5, which was changed by test (4). **Report of Sub-Committee on Fastness to Perspiration.** HUGH CHRISTISON. *Ibid.* **1925**, 6, 858-9.—Expts. with relation to this subject are in progress. L. W. RIGGS

Suggestions for a simple standard for testing the fastness of dyed materials to light. W. F. DEADY. *Proc. Am. Assoc. Textile Chem. Colorists* **1925**, 242-6; *Am. Dyestuff Rept.* **14**, 878-82.—The "suggestions" were made to call forth discussion by the members of the Assoc. L. W. RIGGS

Deterioration of fabrics by light. ANON. *Dept. Sci. Ind. Res. First Report of*

the Fabrics Coordinating Research Committee 1925, 10-3.—The most destructive portion of the solar spectrum is the band bounded by 3900 and 3100 A.U. The best protection for airplane wings is to dye the dope with spirit black. The work is still in progress. **Deterioration of fabrics by microorganisms.** *Ibid* 14-28.—The study proceeded along the following lines: isolation of microorganisms including bacteria, molds and higher organisms that cause destruction of fabrics; the study of the harmful organisms with special regard to the conditions of growth and inhibition; the evolution of treatment to delay or arrest the deterioration due to microorganisms. For preserving fish nets a treatment with Cu oleate and coal tar was best. **The mechanical testing of fabrics.** *Ibid* 29-51.—The details for carrying out tests on the strength of fabrics by means of various machines are given. An essential piece of app. for this work is the const. humidity box which is described. **Fireproofing of fabrics.** *Ibid* 52-3.—This work is in progress.

L. W. RIGGS

Fading tests with an Osram point light lamp. E. HOCHLEIM and E. KNEBEL. *Textilber* 6, 912-11 (1925).—A W arc lamp made by the Osram Co., Berlin, shows a spectral distribution very similar to normal sunlight, and is superior for fading test to either the quartz-tube Hg lamp, which has a very discontinuous spectrum, or the C arc, which gives off too much ultra-violet light. The life of the lamp is some 500 hrs. and decreased intensity of radiation with age may be compensated for with a rheostat.

E. R. CLARK

A new lamp for fading tests. W. D. APPEL. *Proc. Am. Assoc. Textile Chem. Colorists* 1925, 216-9; *Am. Dyestuff Rept* 14, 882-5.—A description of the lamp built at the Bureau of Standards is given.

L. W. RIGGS

Pineapple fiber. R. O. BISHOP and E. A. CURTLER. *Malayan Agr. J.* 13, 293-301 (1925).—Fiber prepd. from the leaves of the fruiting pineapple plant of the "Singapore" variety resembles manila hemp in compn. Although its tensile strength is about 75% that of Manila fiber its qualities warrant further study. The cost of growing, collecting and sepg. the fiber is 1 sh. compared with the cost of producing sisal or Manila fiber.

L. W. RIGGS

Cold bleaching. ROBERT MOHR. *Textilber* 6, 906-12 (1925).—Several bleachers in Germany are using the Mohr process, in which cold NaOH soln. is circulated through the goods, alternately with rinse water, and oxidizing and souring solns. Their experience has been such that the inventor warrants that results at least as good as can be obtained by boiling processes will follow the introduction of the system. The special app. sold by the Zittau Machine Works is recommended. Samples of colored rayon striped fabrics bleached by the Mohr process are exhibited (cf. C. A. 17, 2056).

E. R. CLARK

Chemical analysis of cotton. Waxes of cotton of different origin and their characteristics. L. V. LECOMBER and M. E. PROBERT. *J. Textile Inst* 16, 338-44T (1925).—The wax content fails completely as a means of differentiation of cottons of different geographic origin. **Identification of the fatty ingredients in sized goods.** *Ibid* 345-51T.—Samples of sized yarn and gray cloth known to contain tallow, Japan wax, spermaceti, castor oil, paraffin wax, or mixts. of these substances were extd. with CCl_4 . The results showed that the characteristics of the added fatty ingredient, as deduced from analysis, are in good agreement with the generally accepted values for the particular substances in question.

L. W. RIGGS

New process in the [dry] cleaning industry. ALB. FISCHER. *Warme & Kälte* 27, 53-6 (1925).—The benzine used in washing the clothes is circulated, during the washing, through a centrifugal separator to remove the dirt. The dirt has a fat content of 6.9%, while the benzine contains only 0.76%, which is not objectionable and tends to keep the clothes from absorbing moisture.

ERNEST W. THIEL

Effect of alkalis on wool: Importance of p_H . H. C. CHAPIN. *Proc. Am. Assoc. Textile Chem. Colorists* 1925, 231-3; *Am. Dyestuff Rept* 14, 859-61.—The point of view in this paper is that the amt. of free acid or alkali in a dye soln. does not matter so much as the percent of that free acid or alkali which is active. Thus H_2SO_4 and AcOH or NaOH and NH_4OH of equal neutralizing powers have very different actions in the dye bath because of their different degrees of ionization. Hence the importance of detg. the p_H from which the degree of ionization is estd. **Hydrogen-ion concentration. Its relation to the problems of dyeing.** W. M. SCOTT, E. M. SHELTON and (MISS) HAZEL F. GROVER. *Ibid* 234-7; 862-5; cf. Speakman, C. A. 19, 1200, 2275.—It has proved that the theories of Speakman apply to silk as well as to wool.

L. W. RIGGS

Recent developments in the coloring of acetate silk. H. R. DAVIES. *Proc. Am. Assoc. Textile Chem. Colorists* 1925, 251-4; *Am. Dyestuff Rept* 14, 887-90; cf. C. A. 19, 401.—An address.

L. W. RIGGS

Quantitative studies on the action of alkalis (sodium hydroxide) on rayon silks and of their relative hygroscopic properties. A. K. JOHNSON. *Proc. Am. Assoc. Textile Chem. Colorists* 1925, 238-46; *Am. Dyestuff Rept.* 14, 866, 875-82—The object of this study "was to ascertain the actual losses and their uniformity upon treatment with NaOH, in order (1) to det. the suitability of this reagent under proper conditions for making union fabric analyses, and (2) to establish the factor to be applied to the wt. of the residual fiber mass from the analysis to correct it for the loss from caustic action."

L. W. RIGGS

History and development of bronze printing. OSKAR GAUMNITZ. *Textilber.* 6, 923-7(1925)—An historical account of methods for printing metallic powders on fabrics, with a large no. of modern recipes for adhesives.

E. R. CLARK

Plasticity as applied to artificial silk (VENABLE) 2.

Dyes. S. SOKAL. *Brit.* 233,452, Feb. 16, 1924. Blue and gray vat dyes are obtained by potash fusion of benzylideneacenaphthenone and *o*-hydroxybenzylideneacenaphthenone, resp. Other examples are given of dyes produced similarly from condensation products of similar aldehydes or their chloro-, hydroxy- or amino derivs.

Indigoid dyes. B. MAYER and W. MOSER. *U. S.* 1,567,158, Dec. 29. Glycine is condensed with a 2-halogen-anthraquinone-3-carboxylic acid, the anthraquinone-3-carboxylic acid thus obtained is treated with condensing agents and the indoxyl compds. of the 2,3-anthraquinone series thus formed are converted into indigoid dyes and the latter are halogenated. The halogenated dyes thus produced dye cotton fast red-blue to blue-black and green.

Vat dyes of the thioindigo series. A. W. JOYCE. *U. S.* 1,568,458, Jan. 5. The condensation product from 4-methyl-6-chloro-2,3-diketodihydro-1-thionaphthene and its 2-keto equivs. with 6-ethoxy-3-hydroxy-1-thionaphthene is brominated. A bright red powder is produced, insol. in H₂O, alc. and ether, sol. in PhNO₂ and in concd. H₂SO₄, forming a yellow vat with alk. hyposulfite, dyeing animal and vegetable fibers bright bluish red shades, fast to light, Cl and washing.

Carbocyanine dyes. G. O. GUTKUNST. *U. S.* 1,568,667, Jan. 5. Dyes of the carbocyanine type are obtained by the "condensation on itself" of a naphthoquinaldine alkyl halide, *e. g.*, β -naphthoquinaldine ethiodide with alc. potash in the presence of CHI₃.

Lakes, pigments, etc. COLLOISIL COLOUR CO., LTD. *Brit.* 233,426, Feb. 7, 1924. Basic dyes, *e. g.*, Brilliant Green, are heated with liquid, *e. g.*, boiled with H₂O in the presence of "Neuburger Kieselkreide" or other material consisting at least principally of hydrated silica, to form lakes, pigments or body colors.

Dyeing textile materials. SANDOZ CHEMICAL WORKS. *Brit.* 233,704, May 7, 1924. Reserve effects by local esterification of vegetable fibers, either as yarns, loose material or fabrics, are produced by printing with an alkalizing agent such as concd. alkali, with or without a thickening agent, alc. or an alc. soln. of an alkali alcoholate, then applying an esterifying agent such as an acidyl chloride or anhydride or a sulfochloride, and finally washing. A white reserve on a colored ground is obtained by subsequent dyeing with a substantive dye, and a colored reserve on a white or colored ground is obtained by mixing an excess of dye with the alkalizing agent, with or without subsequent dyeing, or by other dyeing methods. Numerous details are given.

Apparatus for dyeing yarns. FULD & HATCH KNITTING CO. *Brit.* 233,255, Nov. 17, 1924.

Kier for bleaching, dyeing and other treatment of wound yarns. JOHN, THOMAS and JOSEPH BRANDWOOD. *U. S.* 1,567,568, Dec. 29.

Bleaching straw braid. E. W. GEISLER. *U. S.* 1,568,664, Jan. 5. Moist Cl is preliminarily applied to straw braid, to render it more readily penetrated by another bleaching agent which is subsequently used, *e. g.*, H₂O₂.

Linen-like finish on cotton goods. R. L. M. G. HEBERT. *U. S.* 1,567,264, Dec. 29. Cotton fabric is scoured with Na₂CO₃, chlorinated, treated with a bath of 53-53.5° Bé. H₂SO₄ at a temp. not exceeding 15° for 14-18 sec., rinsed and then subjected to a "dressing" treatment.

Spinning threads from cellulose acetate solutions. FARBENFABRIKEN VORM. F. BAYER & CO. *Brit.* 233,342, April 29, 1924. In spinning threads of acetate soln. into a soln. of CaCl₂ or other saline coagulating bath, danger of breakage of the thread is reduced by adding to the bath a solvent or swelling agent for cellulose acetate, *e. g.*, acetone, an alc., acetone-alc., formaldehyde or formaldehyde-acetone.

Balloon envelope material. R. TRENCKMANN and B. TRENCKMANN. U. S. 1,567,556, Dec. 29. A sheet of one or more layers of animal membrane such as gold-beaters' skin is moistened, stretched and treated with a mixt. formed of glue, Turkey red oil, glycerol and $K_2Cr_2O_7$ or formaldehyde. A sheet of fabric such as cloth is then united with the coated membrane under pressure.

Ammonia from waste liquors. J. P. BEMBERG AKT.-GES. Brit. 233,669, May 6, 1924. NH_3 present in waste liquors from the manuf. of artificial silk by the cuprammonium process is recovered by pptn. as $Mg NH_4$ phosphate.

Apparatus for forming and coagulating filaments from viscose. S. A. NEIDICH. U. S. 1,568,687, Jan. 5.

Apparatus for manufacture of artificial silk filaments. AKT.-GES. FÜR ANILIN-FABRIKATION. Brit. 233,298, May 3, 1924.

Apparatus for "dry spinning" of artificial silk filaments. SOC. POUR LA FABRICATION DE LA SOIE RHODIASETA and N. GRILLET. Brit. 233,384, Jan. 3, 1924.

Apparatus for making filaments of artificial silk. A. KAMPF. Brit. 233,268, July 3, 1924.

26 PAINTS, VARNISHES AND RESINS

Modern paint grinding mills. H. KOLLN. *Farbe und Lack* No. 47, 555-7(1925). — Descriptions and illustrations of modern com. mills. F. A. WERTZ

Aluminium bronze powder. J. D. EDWARDS. *Paint, Oil and Chem. Rev.* 80, No. 16, 10, 12(1925). — A brief review of the method of manuf., phys. characteristics, detection and estn. of adulteration and coloring processes. F. A. WERTZ

Fundamental facts about aluminium paint. J. D. EDWARDS. *Paint, Oil and Chem. Rev.* 80, No. 20, 10 2(1925). — Review. F. A. WERTZ

Cadmium pigments. FR. HEPLER. *Farbe und Lack* No. 48, 568-9(1925). — A brief review of the manuf., properties and uses of cadmium yellow (CdS), and of cadmium red (Cd sulfide-selenide) pigments. F. A. WERTZ

China wood oil. MAXIMILIAN TOCH. *J. Soc. Chem. Ind.* 44, 511 2T, 517 8T, 527 8T(1925) (abridged). See C. A. 19, 2277. F. A. WERTZ

Effect of zinc oxide pigments upon rate of oxidation of linseed oil. F. H. RHODES AND R. A. MATHES. *Ind. Eng. Chem.* 18, 30-1(1925). — Some of the previously observed variable effects of ZnO pigments on the rate of oxidation of linseed oil (C. A. 17, 3922) were investigated by using a variety of ZnO pigments of known compn. Pure ZnO has no effect on the oxidation rate; that contg. Pb as an impurity may increase the oxidation rate because of the formation of Pb driers by interaction between oil and pigment. The presence of sol. compds. of Zn causes the linseed oil to coagulate at an earlier stage in the oxidation and to form a harder and less permeable film; but the final amt. of O absorbed in 400 hrs. is less than if $ZnSO_4$ is not present, so that the action of $ZnSO_4$ is not that of an oxidation catalyst. It is probably $ZnSO_4$ which causes the formation of a hard film from a ZnO paint, the hardening action which ZnO imparts to a white lead paint, and the apparent drying action of Zn. F. A. WERTZ

Effect of yellow and brown iron oxide pigments upon rate of oxidation of linseed oil. F. H. RHODES AND J. D. COOPER, JR. *Ind. Eng. Chem.* 17, 1255-7(1925). — Expts. as previously carried out to det. the effect of red Fe oxide pigments on the rate of oxidation of linseed oil (C. A. 18, 3280) were applied to brown and yellow oxides. Others first retard, then accelerate drying of the oil. The initial retardation is caused by adsorption of the Pb drier from the oil; the final acceleration is due to the formation of Fe soaps which act as catalysts. The Fe oxide in an ocher reacts less readily with the drying oil than does the Fe_2O_3 in a red oxide pigment. Siennas and umbers show less initial retardation of drying of the oil than does ocher because the removal of the Pb drier is compensated by the formation of a small quantity of Mn drier. Metallic brown shows a less pronounced influence on the oxidation process. Results are plotted. F. A. WERTZ

Gold and silver pigments for book printing. F. SCHIRMER. *Farbe und Lack* No. 45, 528(1925). — Review of materials used and processes of application. F. A. WERTZ

Priming materials. ALB. FRUMENTOR. *Farbe und Lack* No. 45, 529-30; No. 46, 543-4(1925). — A review principally of various com. and patented primers for wood, metals, etc. F. A. WERTZ

The status of cellulose lacquering. M. WINKLEMAN. *Farbe und Lack* No. 47,

Crystallizing lacquer. W. J. MISKELLA. *Paint, Oil and Drug Rev.* 80, No. 24, 10-1(1925).—A review of the various present and possible uses of tung oil japans which produce a frosted or cryst. effect when baked in an oven having an open flame gas burner in it. F. A. WERTZ

Phenol-formaldehyde resins as constituents of lacquers and varnishes. A. C. HOPPER. *Chem. Age* (London) 13, 370-1(1925).—A review of the solvent constituents of lacquers, of methods suggested for detg. the soly. of resins, of patents aiming to improve the characteristics of artificial and natural resins, and of the A. S. T. M. tests for varnish (C. A. 17, 1337). Artificial resins do not appear to be displacing natural resins in the lacquer industry. F. A. WERTZ

The improving of rosins and copals. R. SCHWARZ. *Farbe und Lack* No. 48, 566-7(1925).—A review of methods and patents for raising the m. p. of rosin by oxidizing the finely divided rosin, for removing impurities from natural resins, etc. F. A. WERTZ

The inter-esterification on heating of fatty acid glycerides with resin acids. K. PISTOR. *Z. anorg. Chem.* 38, 1118-21(1925). See C. A. 20, 117. H. G.

Georgia and Alabama clays as fillers [for paint (WEIGEL) 23. Recovering values from acid sludge [for use as a paint] (U. S. pat. 1,568,261) 22. Chlorinating sulfite liquor [for use as resin substitute] (U. S. pat. 1,567,395) 23.

MORRELL, R. S. AND WOOD, H. R.: **The Chemistry of Drying Oils.** Oil and Colour Chemistry Monographs, edited by R. S. Morrell. London: R. Benn, Ltd. 224 pp. 21s.

Paint. D. TAYLOR. U. S. 1,568,350, Jan. 5. A paint adapted for resisting gas or acid fumes comprises turpentine 2, linseed oil $1\frac{1}{2}$, a Pb compd. such as red lead $16\frac{2}{3}$, mineral red $16\frac{2}{3}$, asbestos powder $1\frac{2}{3}$, port. cement $2\frac{5}{8}$, Zn $1\frac{1}{2}$ and "chill room paint" 48 parts.

Bituminous paint. C. S. FLEMING. U. S. 1,568,215, Jan. 5. A bronzing powder is added to a dark colored bituminous vehicle such as "D" grade asphalt and C_6H_6 to prep. a paint which is suitable for use on roofs, etc.

Manufacture of zinc white. ROBERT LEPSPØE. Norw. 37,515, June 2, 1925. A jet of liquid metallic Zn is blown into a suitable heated chamber by means of compressed air, in which chamber it is burned to zinc white which is gathered in known ways.

Coating for wooden articles. JOHAN SIMONSEN. Danish 34,822, Aug. 3, 1925. Two parts of chalk and 1 part of a dry pigment are stirred with water to a thick paste and then the following ingredients are added: $\frac{1}{4}$ part by wt. of oil, $\frac{1}{4}$ part of lac, $\frac{1}{2}$ part of benzene and 2 parts of gluten.

Composition for removing paint and varnish. E. R. LITTMANN. U. S. 1,568,753, Jan. 5. A satd. aq. soln. of Na nitronaphthalate is mixed with acetone, EtOH, C_6H_6 and toluene.

Liquid enameling composition. C. D. HOCKER. U. S. reissue 16,240, Jan. 5. See original pat. No. 1,422,861, C. A. 16, 3219.

27—FATS, FATTY OILS, WAXES AND SOAPS

E SCHERUBEL

Colloidal reactions in the oil and fat industry. J. LEIMDÖRFER. *Seifensieder Ztg* 52, 791-2, 835-6, 854-5, 874-5, 893-4, 912-3, 931-2, 950-1, 968-9, 987-9(1925).—A popular discussion of the nature of colloid reactions in the fat industry. The ready digestibility of fats is made possible by rendering them by the wet method at low temp., thereby retaining their natural enzymes, while fats that are rendered dry at higher temp. are given a better keeping quality but lose some of their emulsifying property during digestion. Olive oil is the most easily digested oil, coconut oil is less so and may

even cause an unpleasant feeling during digestion by the gradual development of its characteristic odor. A food easily perishable is also easily digested. Refining oils: The removal of free fatty acids by esterifying, distn., alc. soln., and by caustic is discussed; the various phys. reactions when dil. or concd. NaOH is used and the resulting soap stock of Na or Ca base are considered from a colloid viewpoint. Hardening of fats: A catalyst must be insol. in the medium to be acted upon; the increase in surface due to fine particles and their equil. with the coarser suspended particles furnish the tension from which the energy is derived that accelerates chem. reactions. The inactivity of a dead catalyst is caused by the transformation of the suspensoid into a suspension with a corresponding loss in energy. "Poisoning" of a catalyst has its source in some chem. reaction.

Oxidation and polymerization of vegetable oils and their fatty acids. G. S. PETROV AND A. I. DANILOVICH. *Z. dent. Oel-Fett-Ind.* **45**, 669-71, 688-9, 703-5, 723-4 (1925).—The constns. of linseed, sunflower and other oils were detd. during their oxidation at different temps. and are tabulated. Polymerization expts. are also tabulated for temps. 180-300° and distns. for 290-325°, at which latter temps. the oils decompose, yielding distillates of polymerized fatty acids. The original Fahrion method (*Z. angew. Chem.* **1896**, 175) for detg. hydroxy fatty acids does not yield results agreeing with the recorded results of the literature, especially when applied to sunflower oil oxidized at 95-100° and at 160°, at which temps. no oxidized acids are obtained; however, oxidation at 250° yields hydroxy acids by Fahrion's method. P. and D. modified the latter's method by first dissolving the oxidized product in alc., and then shaking the soln. with gasoline to ppt. the insol. hydroxy acids. Comparative results of the 2 methods show that weakly oxidized oils may yield correct results with Fahrion's method, but highly oxidized oils give too high results, and to obtain correct results, an alc. soln. of the product must precede the gasoline extn. as is done in P.'s and D.'s method. Air oxidation of the fatty acids of linseed oil with 0.1% Co acetate for 48 hrs. yields 30.7% hydroxy acids (P.'s and D.'s method) of 132.1 I No. while oxidation under the same conditions with 2% Pb-Mn resmate yields 26.07% hydroxy acids with an I no. of 74.8. Most of the expts. were carried out on sunflower oil, its observed resistance toward oxidation cannot be explained on the basis of chem. constitution or its high content of oleic acid glycerides. *Summary*: (1) The most intensive action occurs at 290-320° when the glycerides are partially decomposed into fatty acids and some acrolein. (2) Polymerization in completely filled high containers results in light colored products of high acidity with little loss of oil, refined oil being used. (3) Open vessels furnish a product of low acidity but dark color. (4) The soaps from oil polymerized in an open vessel are dark, but they are light colored from oil which is polymerized without air access. P. and D. preferably employ a high temp. with partial decompn. of the oil and removal of the resulting fatty acids by superheated steam at diminished pressure.

P. ESCHER

The free acidity of edible oils. ANTONIO CERIOTTI AND ALFREDO SANGUINETTI. *Rev. facultad ciencias* **3**, No. 2, 65-75 (1925).—Of 458 com. pure olive oils of various origin and age only 26 had an acidity exceeding 1.5% oleic acid. It is, therefore, suggested that this figure be generally adopted as the limit of permissible acidity. M. J.

Determination of the melting point of cacao butter. TH. SABALITSCHKA. *Z. angew. Chem.* **38**, 1013-4 (1925).—Results of previous workers have been confirmed, that it is necessary to leave the m. p. tube on ice for several weeks before making the detn. in order to obtain complete solidification and thus the correct m. p. W. B. P.

A survey of equipment used in modern soap manufacture. IV. C. RICHTER. *Industria saponiera* **25**, 239-42 (1925); *C. A.* **20**, 304.—An illustrated description of machinery for mixing, automatic driers, presses, cutters, etc.

C. C. DAVIS

The determination of the turbidity point of soap solutions. K. BRAUN. *Chem.-Zig.* **49**, 1012 (1925). III.—The turbidity point of a soap soln. is that temp. at which a soln. contg. 3% fatty acids as an alkali salt begins to become turbid on cooling. The detn. may be made with an app. protected by trade-mark No. 920,816, consisting of a beaker inside another one that has an insulating mantle with 2 slits cut in at opposite sides, and a source of light behind one of them. The warm soap soln. is poured into the inside beaker, the outer one contg. hot H₂O. The thermometer or a sep. stirrer may be used to keep the temp. uniform. When turbidity occurs, the temp. is recorded.

P. ESCHER

A new method of determination of rosin in soap. G. DE BELSUNCE. *Bull. mat. grasses* No. **4**, 70-85 (1925).—The following method, based on the formation of Al resinate, is quicker and more convenient than the Twitchell method and is more accurate with low rosin contents. Dissolve 3-3.5g. of soap on the water bath in 60 cc.

H₂O in a 300-cc. wide-necked flask, allow to cool slowly to room temp., if the soln. gels add 20 cc. H₂O, redissolve, and let cool, pour the soln. with stirring in a mixt. of 20 cc. H₂O and 16.5 cc. Al₂(SO₄)₃ (55.5 g. in 1 l. of H₂O) (both solns. should be at a temp. not over 23°), immediately pour on a fluted filter, wash abundantly with cold H₂O till the washings are neutral. Without waiting for the last traces of H₂O to drain, wash the ppt. successively with five 15-cc. portions of 65% EtOH, 2 of 90% EtOH and 3 of 65% EtOH, if necessary remove the ppt. from the filter, triturate with 15 cc. of 65% EtOH and filter. All washings should be carried out at not over 23°. Titrate the combined 1st 10 alc. washings with *N* NaOH, add the last washing, transfer to a tared 300-cc. Soxhlet extn. flask, distil off the EtOH, dry first on the water bath and then in the oven at 100–5° to const. wt. The wt., corrected for the Na₂O used in the titration, gives the rosin present in the soap. The acids weighed are fatty acids which were displaced by the rosin acids and none of the latter is dissolved out. By assuming a mol. wt. of 287 for abietic acid, the wt. of acids calcd. from the titration should agree within 20% with the wt. found. In about 60% analyses B. found good agreement between the results of the titration and the weighing; but the former cannot safely be used for detg. the rosin. With 3–15% rosin the method gives result: agreeing with those obtained *via* Twitchell; with less than 3% rosin it is more accurate than the Twitchell method, and with more than 18% rosin it is inapplicable. In discussing the mechanism of the reaction of liberation of the fatty acids, from the fact that the latter are equal to the wt. of rosin and not equiv. to the rosin acids, B. considers that the rosin hydrocarbons must act in some physico-chem. or purely phys. manner. Wolff and Dorn (*C. A.* 16, 349) observed a somewhat similar phenomenon in investigating the nature of the ppt. causing turbidity in varnishes contg. driers. A. P. C.

Saponification under pressure. A. WELTER. *Z. deut. Oel-Fett-Ind.* 45, 685 6 (1925).—Referring to Löffl's (*C. A.* 19, 3606) and Stiepel's articles (*C. A.* 20, 514) on autoclave sapon., W. reports that he had successfully introduced pressure-sapon. into his factory 20 yrs. ago, but had abandoned it again on account of the danger of an explosion by a sudden rise of pressure when sapon. set in late as sometimes happened with cottonseed oil. By using fatty acids instead of oil and Na₂CO₃ a very uniform and gradual sapon. takes place if the acids are pumped in a steady stream into the hot Na₂CO₃ soln. As a safety measure W. had mounted a catch-all tank above the autoclave and had them connected with each other by a 200 mm. pipe contg. a Pb plate as a seal, the thickness of which was so adjusted as to give way at 6 atm. pressure. Sapon. is complete after 1½ hrs. at 3 atm. with NaOH; even Na₂CO₃ will saponify neutral fats under pressure in contradiction to statements in text books. When W. used mixts. of caustic and carbonates in open kettles, as much as 18% K₂CO₃ had participated in the sapon. of neutral cottonseed oil. For very large scale operations W. suggests preliminary sapon. in open kettles, followed by finishing in smaller autoclaves, or still better by pumping the soap through coils of pipes, heated to 150°.

P. ESCHER

Gloss and smoothness in milled toilet soaps. J. LIEBLEIN. *Z. deut. Oel-Fett-Ind.* 45, 689–90(1925).—L. discusses the causes and remedies for brittle or cracking cakes of toilet soaps.

P. ESCHER

Rancidity and spot formation in toilet soaps. C. BERGELL. *Z. deut. Oel-Fett-Ind.* 45, 653(1925).—Considerable trouble was recently experienced by toilet soaps turning rancid and developing spots, on account of the poor quality of certain by-product tallows which had been purified and were sold as high-grade tallows. Their detection is possible by boiling a test batch in the lab. and examg. the lyes: normal tallows yield only very small quantities of normal fatty acids of an acid no. of 200–210; the dangerous tallows yield ¼ to 1% of fatty acids, mostly gasoline-insol. hydroxy acids of an acid no. of 300 or over and an I no. of 20–30.

P. ESCHER

New fields of application for trichloroethylene. R. DECKERT. *Seifensieder Ztg.* 52, 975–6(1925).—A recipe is given for an alc. soln. of Na oleate which, after being mixed with about 9 parts by wt. of trichloroethylene, forms a permanent emulsion which is successful as a washing medium in the textile industry, and is also useful in dissolving old paint from furniture, textiles, etc., or in restoring colored leather.

P. ESCHER

Cacao beans and cacao products (FINCKE) 12. Estimation of water in oils and fats (SEABER) 22. Marine animal oils (ANDRÉ, CANAL) 10. Filter for reclaiming animal fats (U. S. pat. 1,567,989) 22. Purifying oils (Swed. pat. 59,250) 22. Oil filter (U. S. pat. 1,568,796) 1. Apparatus for neutralizing and bleaching oils under a vacuum (Brit. pat. 233,345) 1.

Refining fatty oils. HENRIK BULL. Norw. 41,590, July 6, 1925. The oil is mixed with aq. NH_4OH and heated to such a temp. that the NH_4 salts of the fatty acids will accumulate as a cohesive soap paste and the upper layer of oil can be sepd.

Manufacture of emulsions of marine oils. SVANEAPOTHEKET, BERGEN. Norw. 41,744, Aug. 17, 1925. The process is carried out in an atm. of CO_2 , N_2 or other O-free indifferent gas.

Separating oil from whale speck, flesh and other similar fatty materials. KRISTIAN HOLTER and SVERRE THUNE. Norw. 41,828, Sept. 7, 1925. The materials are disintegrated, and steam or hot water is applied during or immediately after the disintegration.

Boiler for liver-oil manufacture. OTTO HALSET. Norw. 41,403, June 2, 1925. Mech. features.

Wax mixture for treating thread. J. FRY. U. S. 1,567,497, Dec. 29. "Shoemaker's prep'd. machinery wax" 70, boiled linseed oil 20, banana oil 5 and oil of sassafras 5 parts.

Chromium soap. T. T. GRAY. U. S. 1,567,049, Dec. 29. A mixt. of Cr soap and an alkali metal soap in approx. equal proportions is adapted for use in dentifrices or, for shaving, in cold creams, etc.

Soap drier. C. W. AIKEN. U. S. 1,568,791, Jan. 5

Apparatus for purifying used soap solutions in laundries, etc. J. E. CAPS. U. S. 1,567,033, Dec. 29.

Washing powder. A. LINDAHL. Swed. 58,788, May 27, 1925. Finely divided soda and oil and fatty acids are blown into a container by means of compressed air through an atomizer. By this procedure the materials are mixed thoroughly and the saponification will take place instantaneously. The resulting dry powder is accumulated on the bottom of the vessel.

Washing powder. HAPPAHS INDUSTRI A.-B. Swed. 59,006, July 1, 1925. A liquid mixt. of soap, soda and a filler is brought in pulverulent state by cooling below the temp. of the surrounding air, or below the freezing point, under const. stirring. The powder formed is heated to the air temp. without being exposed to the air.

28—SUGAR, STARCH AND GUMS

F. W. ZIERBAN

The influence of the degree of extraction on the purity of sugar cane juice. WM. F. CROSS. *Rev. ind. agr. Tucuman* 15, 160-1 (1925).—C's. expts. and those published in the *Annual Synopsis of Mill Data* of the Expt. Station of Java lead to the following conclusions: The lab. mill gives about the same extn. as the first mill in the factory, approx. 60%. The highest extn. reached in a modern plant is 80%. The difference in purity between the first extn. and the juice resulting from intense milling is only 1-3%. The lab. results are therefore sufficiently reliable for plant control.

MARY JACOBSEN

Plasticity of starch paste (BERGQUIST) 2.

FAIRRIE, GEOFFREY: **Sugar.** Liverpool: Fairrie & Co., Ltd. 233 pp. 12s 6d. Reviewed in *Chemistry and Industry* 44, 1188 (1925).

Sugar manufacture. A. P. LEONARD. U. S. 1,568,512, Jan. 5. Bagasse is passed successively through a series of crushing mills. Juice from the foremost of the mills is conveyed to separators, clear juice is extd. from the separators and sugar is sepd. from the clear juice of one of the separators. H_2O is introduced into the residuum in another separator and clear juice from the separators is returned to an intermediate mill of the series and juice from the intermediate mills is led to the foremost mills. Juice from the last mill of the series is returned to a mill in advance of that receiving the liquid from the separators, and, from said advance mills, juice is returned to the foremost mill.

Electrolytic treatment of beetroot molasses or fermentation residues. Y. TAKAYAMA. Brit. 233,196, July 5, 1924. Beet molasses, or the residue remaining after molasses fermentation and distn. of alc., is electrolyzed so that glutamic, glutimic and

succinic acids or their salts are obtained at the anode and betaine and KOH and soda at the cathode.

Thin boiling starch. J. R. MACMILLAN. U. S. 1,567,609, Dec. 29. Dry starch is exposed to contact with gaseous Cl for about 1 min. and then treated with NH_3 , NaHCO_3 or other "anti-chlor."

Apparatus for manufacturing potato starch. L. P. HELTNE. Norw. 40,204, June 29, 1925.

29—LEATHER AND GLUE

ALLEN ROGERS

Acidity of chrome-tanned leather. AUG. C. ORTHMANN. *J. Am. Leather Chem. Assoc.* **21**, 30-3(1926).—The theory is advanced that a part or all of the sulfate combined with chrome leather may be in combination with the Cr rather than with the protein and not capable of hydrolysis in water. J. A. WILSON

An internal complex salt formation as the mechanism of chrome tanning. K. H. GUSTAVSON. *J. Am. Leather Chem. Assoc.* **21**, 22-30(1926).—The conditions of the acid and basic groups of collagen both play parts in the fixation of cathodic Cr. The acid groups of collagen probably combine with Cr through the primary valences and the basic groups through the secondary valences, the result being an internal complex salt. Anodic Cr fixation (oxalato compd.) shows a max. rate in the isoelec. zone of the protein and is probably of the residual valence type and is distinctly different from the combination of Cr cations with collagen. J. A. WILSON

Methods for measuring the enzyme activities of bating materials. J. A. WILSON AND H. B. MERRILL. *J. Am. Leather Chem. Assoc.* **21**, 2-18(1926). Detailed methods for detg. the activity of pancreatins upon keratose, elastin, collagen, casein and fat. J. A. WILSON

Tannin content of western hemlock after immersion in sea water. H. L. TEMPLETON AND E. C. SHERRARD. *Ind. Eng. Chem.* **18**, 101-2(1926).—Tannin contents of 11.82, 16.16, 12.99 and 16.38 were found after immersion periods of 0, 30, 60 and 90 days, resp. J. A. WILSON

Determination of water content in liquid glue. WM. A. KINGMAN. *Ind. Eng. Chem.* **18**, 93-4(1926).—The sample is floated on tetrachloroethane, which, on distn from a flask heated by an oil bath, carries over all the water. The condensed distillate is caught in a graduated tube. The water floats to the top and is measured. JEROME ALEXANDER

Gelatin and collagen (KATZ, GERNGROSS) 2. Collagen (HERZOG, GONELL) 2. Chlorinating sulfite liquor [for use as tanning substitute] (U. S. pat. 1,567,395) 23.

Tanning. J. HELL. U. S. 1,567,644, Dec. 29. Previous to tanning, hides or skins are treated with substances such as MgSO_4 and NaHCO_3 or Na_2CO_3 which react to form a substantially insol. Mg salt within the structure of the hide or skin. This pretreatment serves to render the leather produced resistant to heating (without becoming stiff).

Shoe grease. G. A. H. CALISSENDORFF. Swed. 59,330, Aug. 26, 1925. A mixt of about 60% by wt. of paraffin wax, 30% castor oil, 9% benzine, 0.9% lampblack or yellow ochre and 0.1% of turpentine.

Grease for shoe soles. V. A. H. MARCUSLUND. Danish 35,049, Sept. 12, 1925. A mixt. of oil, a soln. of gum, carbolineum and optionally CuSO_4 worked to an emulsion.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Guayule rubber. D. A. CUTLER. *Rubber Age* **18**, 202(1925).—An address dealing with the history, production, uses and technical value of guayule. C. C. DAVIS

Uses of rubber latex. S. B. NEILEY. *Rubber Age* **18**, 201(1925).—An historical description, with an itemized account of the most recent and various uses of latex. C. C. DAVIS

Coagulation phenomena in Hevea latex. III. Influence of some chemicals. O. DE VRIES AND N. BEUMÉE-NIEUWLAND. *Arch. Rubbercultuur* **9**, 590-630(1925);

Ibid 631-54; (In English), cf. C. A. 19, 419.—Various disinfectants were tested for their ability to coagulate fresh latex, for their toxicity toward the enzyme coalse and for their coalescing power on heated, flocculated latex (the B-mixt. described previously). H_2S , HCN, NaOCl and I had none of these properties. HCN retarded spontaneous coagulation due to bacteria. Of the substances tested, only quinosol was a strong coagulant, while large amts. of PhMe and of $CHCl_3$ caused coagulation. Thymol, β -naphthol and quinine, however, accelerated coagulation by HOAc, and since they had strong coalescing power, coagulation and coalescence in heated latex are independent phenomena. In fresh latex the processes overlap, for quinosol, though it had only slight coalescing power and inactivated the coalse, gave a coagulum and not a flocculate.

F. H. YORSTON

The structure of rubber. II. PAUL BARY. *Rev. gén. colloïdes* 3, 263 9(1925), cf. C. A. 20, 310.—A discussion of the reticular, cellular and solid solu hypotheses, of coagulation and the resulting structure and of the effects of mastication on the latter. Only a reticular structure explains the successive transformations which rubber undergoes. Rubber itself, *vis.*, the internal liquid of the cells (cf. Hauser, C. A. 19, 1962, 2280), has at each temp. a mean degree of polymerization which increases with decrease in temp. and *vice versa*. There is a temp. at which rubber has elastic properties which are due to a network structure of highly polymerized rubber impregnated with less polymerized rubber with mols. having a certain mobility. Mech. work ruptures the mol. chains of the network, as a result of which depolymerization begins. Moderate work such as stretching forces the less polymerized interreticular substance to flow through the meshes, with depolymerization and consequent increase in fluidity. This is the cause of the slow increase of the ultimate elongation and a recovery which is slower than can be explained merely by partial repolymerization. That mech. work causes depolymerization is also shown by the influence of mastication on vulcanization. The elasticity of rubber is then due to an unstable state of polymerization, the degree of which varies greatly through the mass. Equil. is attained very slowly and is partially destroyed by mech. deformation and by heat. Two mutually sol. components are present, the proportions of which vary according to external conditions. Vulcanization replaces the unstable bonds of natural polymerization by a more stable polymerization due to the action of S, and necessarily changes the phys. properties. Impurities in natural rubber probably render the state of polymerization particularly unstable compared with synthetic rubber, as a result of which the latter is less elastic and vulcanizes less readily.

C. C. DAVIS

The two-phase structure of rubber. I. E. A. HAUSER. *Rev. gén. colloïdes* 3, 289-93(1925).—A review and discussion of various theories proposed to explain the structure of rubber, including 29 references.

C. C. DAVIS

The significance of the protein film. H. P. STEVENS. *India Rubber J.* 70, 1059-60 (1925).—Photographs of thin films of rubber swollen in C_6H_6 are shown as evidence that the cellular structure of protein persists after such dispersion and that after distention to the bursting point the fragments are still visible. Crepe disperses more readily in solvents and with less swelling than sheet rubber because the former has received an earlier treatment drastic enough to destroy at least partially the protein envelopes. On long standing of a dispersion of milled crepe in C_6H_6 , the fragments of protein are deposited, a phenomenon not easily reconcilable with the observation of Sebrell, Park and Martin (C. A. 20, 309) that milled crepe dispersed in C_6H_6 has a structure similar to that of dried latex. Exception is also taken to their conclusion that grain effects in milled rubber are due partly to the presence of discrete latex globules. Milling of either crepe or sheet eventually causes complete destruction of the protein envelopes and it is at least more likely that the protein fragments act like pigments in causing a grain effect both before and after vulcanization. Crepe from rubber coagulated with tannic acid gives in C_6H_6 a gel similar to that from sheet rubber, perhaps because of a toughening effect of the tannic acid on the protein.

C. C. D

Observations on F. Kirchof's paper on the "Combination of water with rubber." O. DE VRIES. *Kolloid-Z.* 37, 178-9(1925); cf. C. A. 19, 1065.—Previous work is pointed out which seems to have been in part or wholly overlooked by K. (cf. de V., *Arch. Rubbercultuur* 7, 436(1913); C. A. 15, 2563; 17, 2796). The reversibility of the coagulation is questioned.

H. M. McLAUGHLIN

Rubber compounding. I. WEBSTER NORRIS. *India Rubber World* 73, 189-90 (1926).—The early development of compounding is described, with rules, materials, methods and typical formulas of the earlier period.

C. C. DAVIS

Lime in the manufacture of rubber. H. L. FISHER. *Rock Products* 28, No. 18, 56-7(1925).

RAYMOND WILSON

Handling solvents in the rubber industry. D. T. WRIGHT. *India Rubber World* **73**, 202-3(1926).—Carefully composed *specifications* should include d., initial and final b. p. and in special cases the % distd. at 2 or more intermediate points. Naphtha or benzene dild. to 40:60 with CCl_4 has less fire hazard than kerosene, and by dilg. to 30:70 the mixt. will not flash at its b. p. Fires of solvents offer special difficulties, for water tends to spread the fire. Foam systems, steam, CCl_4 , sand and Na_2CO_3 are all effective under various conditions. Maintenance of a high humidity is of great value in preventing static discharges.

C. C. DAVIS

Measuring effects of corona on rubber. Deleterious effects produced by ozone when rubber is subjected to corona and tension simultaneously. Significance in testing electrical rubber goods. F. L. HAUSHALTER. *India Rubber J.* **70**, 897-9(1925).—See *C. A.* **19**, 2785.

C. C. DAVIS

The "mouldy rot" disease of *Hevea brasiliensis* in Malaya. F. W. SOUTH AND A. SHARPLES. *Dept. Agr., Straits Settlements and Federated Malay States, Bull.* No. **37**, 31 pp.(1925).—The disease is caused by *Sphaeronema fimbriatum* and is very easily disseminated. Immediate and prolonged disinfectant or prophylactic treatment is necessary, the best results being obtained by painting with 20% "agrisol" soln., an unspecified com. disinfectant (manufd. by Major & Co., Hull, England). The bacteriology of *S. fimbriatum* and culture and inoculation expts are described

C. C. DAVIS

Georgia and Alabama clays as fillers [for rubber] (WEIGEL) **23**. Leaf diseases of *Hevea* (WRIGHT) **15**. The Ostwald viscometer, as a consistometer (HERSCHEL, BUCKLEY) **2**. Combining rubber with paper pulp (U. S. pat. 1,567,646) **23**. Hardened asphalt products (Swed. pat. 59,754) **22**.

Crude rubber from latex. GENERAL RUBBER CO. Brit. 233,651, May 12, 1924. Latex is desiccated (*e. g.*, by the process described in Brit. 157,978, *C. A.* **15**, 2019) to obtain substantially all the solid constituents and the product is heated until it is of dark color. A crude rubber is thus obtained which is more plastic and "tacky" than ordinary sprayed rubber.

Mixing rubber latex with other substances. E. HOPKINSON U. S. 1,567,506, Dec. 29. Rubber latex is mixed with (a) an aq. emulsion of an oil or other liquid insol. in H_2O ; (b) an emulsion formed from an aq. liquid and a soln. of a gum or resin or similar material in CCl_4 , C_6H_6 , turpentine or other org. solvent; and (c) an aq. suspension of finely divided solid particles, *e. g.*, C black, clay or ground cork. Substantially all the H_2O is then removed from the composite mixt by evapn. to obtain a product adapted for making vulcanized articles. Vulcanizing agents may be added to the aq. mixts.

Forming rubber articles from latex. G. VENOSTA. Brit. 233,458, Feb. 19, 1924. Gloves or other seamless rubber articles are formed by dipping a mold into latex which has been artificially concd. and which may have been dialyzed before concn., allowing the H_2O to evap. from the latex, and vulcanizing the product. Various compounding and vulcanizing ingredients may be added to the latex.

Aqueous rubber dispersions. W. B. PRATT. Brit. 233,370, Nov. 7, 1923. An aq. dispersion of previously coagulated rubber is prepd. by incorporating H_2O into a rubber mass and then subjecting it to stretching with gradual addn. of H_2O until a paste, and finally, a liquid, is obtained. The penetration of the rubber by the H_2O may be facilitated by the use of glue, albumin, casein, gum arabic, sugars, gluten, starch, dextrin or colloidal clay; and soap, saponin or the like may be added to the H_2O for the final dispersion. Various compounding ingredients may be added to the rubber prior to its dispersion, including oils, pigments, vulcanizing agents and accelerators. Cf. *C. A.* **19**, 420.

Apparatus for grinding, mixing or masticating rubber. F. GARNER AND A. HALL U. S. 1,567,587, Dec. 29.

Vulcanizing apparatus. H. E. L. HOVMANN. Danish 34,676, June 29, 1925.

CHEMICAL ABSTRACTS

Vol. 20.

MARCH 10, 1926

No. 5

1—APPARATUS AND PLANT EQUIPMENT

W. I. BADGER

Defects in chemical apparatus. D. B. DOTT. *Pharm. J.* **115**, 470-1(1925).—Errors in graduation of cylinders and burets are referred to. In alkalimetry, the use of burets of slightly tinted glass, red for acids, bluish for alkalis, is suggested. The stem of a sepg funnel should have a bevelled end, and a bore of 6-7 mm. even for a small separator

S. WALDBOTT

Important new equipment exhibited at the American Gas Association Convention. ANON. *Chem. Met. Eng.* **32**, 883(1925). Mention is made of the Cutler-Hammer gas mixing control which maintains the heating value of the mixed gases const., Koppers new naphthalene-removing equipment, and U. G. I. rotating grate water-gas generator

W. L. McCABE

New engineering equipment marks tenth chemical show. ANON. *Chem. Met. Eng.* **32**, 820-1(1925).—Mention is made of the Miller rubber-lined acid containers, Cr plating, Devine superimposed multiple effect evaporator, Buffalo distd water evaporator, a new homogenizing mill by the National Homogenizer Co., Annis-Knight gas generator, Freas rubber aging bath, and the Kemp system of premixing fuel gas with any desired amt. of air.

W. L. McCABE

Continuous extraction apparatus. J. W. MACMYN. *Ind. Chemist* **1**, 376(1925).—In the app. described by Sando (*C. I.* **19**, 421) the glass container is replaced by a tin bottle provided with a brass-wire gauze. This prevents the carrying over in siphoning of solids of small grain size

E. H.

Continuous extraction apparatus. G. S. WRIGHT. *Ind. Chemist* **1**, 448(1925).—The app. of the preceding abstract is improved by inserting a bulb in the siphon that returns intermittently the solvent to the distg. flask. The bulb prevents any break in the column of siphoning liquid, which otherwise tends to make siphoning continuous instead of intermittent.

E. G. R. ARDAGH

Improvements in analytical crucibles. J. D. M. SMITH. *J. Soc. Chem. Ind.* **44**, 539-40T(1925).—The use of a squat-shaped crucible with an interior fitting serrated lid avoids spattering, spurting and creeping. The alkali and alkaline earth metals can be detd. as anhydrous cryst. sulfates by igniting with H_2SO_4 , boiling with a mixt. of HNO_3 and HCl , and adding concd. H_2SO_4 , followed by ignition at a dull red heat.

T. S. CARSWELL

A method for the determination of small quantities of swelling. P. A. THIESSEN AND C. CARIUS. *Kolloid-Z. Special No.*, Apr. 1, 1925, 245-52.—The scale pans were removed from an analytical balance and by a system of levers one end of the balance beam was connected to a mirror rotatable about an axis parallel to the axis of the balance beam. The amt. of rotation of the mirror could be measured by a telescope and scale. In the other end of the balance beam was suspended a pestle-shaped glass rod in a glass dish which rested on a micrometer table. A circular glass plate was cemented to the bottom of the dish. Changes in the position of the pestle-shaped rod which were to be read on the scale by means of the telescope were standardized by the use of glass plates of known thickness (0.085 to 0.243 mm). The substance to be measured was stamped into a circular disk and laid on the glass plate under the pestle-shaped rod. The progress of the swelling could be accurately read on the scale. With a slight modification swelling either in vapors or in liquids could be detd. Expansion and contraction as well as substances in the form of ribbons or fibers could be investigated.

H. M. McLAUGHLIN

Pipets for potash work. C. M. BIBLE. *Ind. Eng. Chem.* **18**, 143(1926). E. J. C.

A rapid balance for weighing pills and tablets. HÅKAN SAN. *Svensk Farm. Tids.* **29**, 466-7; *Svensk Kem. Tids.* **37**, 284-5(1925).—A Becker-type instrument with a long pointer and long scale with a capacity of 5 mg. to 10 g. Illustration from a photograph.

A. R. ROSE

A small resistance thermometer. GEO. F. TAYLOR. *Phys. Rev.* **26**, 841-50 (1925).—The thermometer described consists of a Pb filament 1.5 cm. long and 2×10^{-3} mm. in diam. in a glass wall 4×10^{-6} mm. thick, embedded in a typemetal which makes contact with one end of the filament. It fits in a sheath 6.4 cm. long and 0.24 cm. diam. and has a temp. lag of 10 sec. Its resistance is 448 ohms so that a portable galvanometer gives a sensitivity of 0.005°. Full details of its construction are given.

D. C. BARDWELL

Improved salt-bridge. HANS T. STERN. *J. Phys. Chem.* **29**, 1583-4 (1925).—The salt bridge for electrometric work, customarily H-shaped, can be of wider use if a stopcock is applied and one paper plug is omitted.

JOHN T. STERN

Note on the capacity and graduations of dispensing bottles. W. S. STANNARD. *Pharm. J.* **115**, 469-70 (1925).—Detns. of capacity of 42 bottles in 7 groups (1-12 oz.) showed variations from -5% to +15%; only 12 had the indicated capacity. In a set of graduated bottles, 114 intervals were tested, of which 66 were accurate; yet not a single bottle was graduated accurately throughout. In dispensing, total vols. as well as doses should therefore be measured only by means of properly graduated glasses.

S. WALDBOTT

A simple form of gas circulating apparatus. A. R. PEARSON AND J. S. G. THOMAS. *J. Chem. Soc.* **127**, 2450-1 (1925).—A closed side bulb in a Hg U-tube is heated until there is a difference in pressure of 2-3 in. in the Hg, whereupon the Hg is set in oscillation by quickly opening and closing a valve at the top of the side of the U-tube with the side bulb. The pressure in the bulb is thereby reduced to that on the other side of the U-tube and the Hg then oscillates as long as the bulb is heated. By connecting suitable glass ball valves in each arm of a T-tube (in the system and connected by its stem with the top of the second side of the U-tube) gas is forced through the system.

C. C. DAVIS

Regulators for continuous gas sampling apparatus. FRIEDRICH PLENZ. *Gas u. Wasserfack.* **68**, 810-2 (1925).—In the usual form of Mariotte bottle a small tube may be used, closed at the bottom but open at the top, and into which the gas inlet tube dips. A siphon connects the H₂O in the tube with the main body of liquid in the bottle, so that the action of the aspirator is as usual save that the gas comes in contact only with the small quantity of liquid in the tube. Other devices for obtaining a const. head during the sampling period are described.

W. B. PLUMMER

Ultrafiltration under pressure. B. BRUKNER AND W. OVERBECK. *Kolloid-Z. Special No.*, Apr. 1, 1925, 192-6.—The app. consists of a bell-jar-shaped brass vessel with walls 1 cm. thick, fastened to a smooth perforated base plate bolted to a tripod, and at the top a valve housing with manometer. A magnetically operated stirrer is provided. The current cycle is opened and closed automatically by a special form of circuit breaker. The app. can be used with 100 atms. pressure. The time required to filter 300 cc. of a satd. soln. of Congo red without stirring was 14 days. With stirring an equal vol. of the same soln. was filtered in less than 2 days. H. M. McLAUGHLIN

Discharge in rarefied gases and a modified McLeod gage. E. PERUCCA. *Nuovo cimento* [N.S.] **2**, 287-94 (1925).—A modified McLeod gage has been developed which depends upon the variation in elec. cond. of air at different pressures and at high voltage. With this modification it has been possible to increase the limit of measurement from the usual value of $1-2 \times 10^{-6}$ mm. of Hg to a value of 1×10^{-7} mm. of Hg. L. T. F.

Laboratory apparatus for the wet grinding of plant tissues out of contact with air. W. A. ROACH. *Biochem. J.* **19**, 783-6 (1925).—An inverted glass bell-jar is suspended by its rim through a circular hole in a table and is cushioned by a ring of rubber. The bell-jar is held in position by the brass plate which is attached to the table by bolts and thumb screws. A second ring of rubber placed between the brass plate and the bell-jar serves to make an air-tight joint between them. Passing through the brass plate is a shaft carrying an alundum grinding wheel of just slightly less diam. than the bell-jar. Potatoes to be ground up are inserted through a cylindrical brass tube which is fitted tightly into a hole in the brass plate so that its basal end almost touches the grinding wheel. A second but much shorter brass tube of the same diam. is soldered into a second hole in the plate lying just to the side of the first. A cylinder of strong rubber is attached to the short brass tube and is closed at its free end with a block of wood into which is fitted the handle of a steel wire brush to remove the material from the grinding wheel. There are rubber-tube connections between the brass cylinder and the rubber cylinder and between the brass cylinder and the lower end of the bell-jar. Inert gas enters through the lower end of the bell-jar.

BENJAMIN HARROW

Laboratory mixing machine for solids. R. M. HIXON. *Ind. Eng. Chem.* **18**, 138 (1926).

E. J. C.

Special tool for packing condenser tubes. M. C. COCKSHOTT. *Chem. Met. Eng.* 32, 881-2(1925).—An adaptation of an ordinary brace carrying a packing tool and a spoon of packing instead of a bit.

An instrument for the rapid production of Laue photographs. J. T. NORTON. *J. Optical Soc. Am.* 12, 27-9(1926). W. L. McCABE E. J. C.

An X-ray spectrometer with which wave lengths are read directly on an ordinary micrometer screen. W. W. NICHOLAS. *J. Optical Soc. Am.* 12, 45-6(1926). E. J. C.

A new intensimeter for ultra-violet rays. A. GYEMANT. *J. Optical Soc. Am.* 12, 65-8(1926). E. J. C.

Crystal orientation apparatus for X-ray photographs. K. HERRMANN. *Z. Krist.* 62, 218-22(1926).—H. describes a theodolite goniometer modified for X-ray analysis of crystals. Patented. I. S. RAMSDELL

A new self-registering spectrothermograph. J. W. ELLIS. *J. Optical Soc. Am.* 11, 647-52(1925).—An improved app. with greater dispersion and resolution for infrared measurements is described. H. R. MOORE

Apparatus for the volumetric determination of small quantities of O and CO in N, etc. (GEISSLER) 7.

Acetylene generator. D. H. DANLEY U. S. 1,563,722, Jan. 12.

Acetylene generator. D. A. MILAM. U. S. 1,568,988, Jan. 12.

Thermostat for controlling gas heaters, etc. L. MOMBARUZZO. U. S. 1,570,446, Jan. 19.

Thermostat controlling flow of hot and cold liquids to a mixing chamber. H. H. SQUARE. Brit. 234,563, March 5, 1924

Thermostat mounting. A. J. OTTO and C. A. OTTO. U. S. 1,569,782, Jan. 12.

Filter for water, etc. R. H. L. PENNELL U. S. 1,570,523, Jan. 19.

Filters for acids and other liquids. D. M. GOETSCHEUS and L. F. VOGT. U. S. 1,569,627-8, Jan. 12.

Filter for liquids. R. SELIGMAN. Brit. 234,155, Jan. 21, 1924.

Filtering tank for liquids. I. B. TANNER. U. S. 1,569,896, Jan. 19.

Apparatus (with rotating disks) for washing and cooling gases. E. THEISEN. Brit. 234,109, May 15, 1924.

Apparatus for filtering metallurgical, sugar or other solutions. P. H. CRAWFORD and J. F. ABBEMA. U. S. 1,570,374, Jan. 19.

Oxidation, reduction or destructive distillation of different materials. H. G. FLODIN and E. G. T. GUSTAFSSON. Swed. 59,982, Dec. 8, 1925. The materials are treated with hot, whirling gases passed in counter-current through a system of two combined furnaces of suitable types. Mech. features.

Drying and sorting apparatus for materials of different grain sizes. O. NORDSTROEM. Swed. 59,860, Nov. 10, 1925.

Apparatus for determining the mechanical composition of pulverulent materials. S. L. A. ODÉN. Swed. 59,794, Nov. 3, 1925. The content of the different grain sizes is detd. by prepg. a suspension of the material in a suitable liquid and measuring the sp. gr. of the suspension at certain intervals after the beginning of the sedimentation. Mech. features.

Furnace for enamelled articles, etc. H. H. DODGE. U. S. 1,570,340, Jan. 19.

Gas-fired shaft-kiln for burning limestone, silica, etc. DOWSON & MASON GAS PLANT CO., LTD., J. PATON and E. W. MAWBY. Brit. 234,310, July 3, 1924.

Hardness-testing apparatus. H. HENKEL. U. S. 1,570,249, Jan. 19.

Annealing pot surrounded by inert gas. F. GIESECKE. Brit. 234,779, May 30, 1924.

Thermionic valves. E. Y. ROBINSON and METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Brit. 234,565, March 7, 1924. A cathode coated with oxides of Ba and Sr or the like is further provided with a protective coating of a gum, resin, cellulose or cellulose deriv. to protect the oxides from H₂O vapor and CO₂. The oxide coating may be applied to a Pt Ir strip contg. 10% Ir by electrodeposition in a bath consisting of a mixt. of Ba and Sr iodides dissolved in acetone with a trace of H₂O. Cf. C. A. 19, 911.

Thermionic valves. DEUTSCHE GLÜHFADENFABRIK R. KURTZ and P. SCHWARZKOPF GES. and P. SCHWARZKOPF. Brit. 234,435, May 21, 1924. In forming filaments, a mixt. of molybdic acid with Th oxide or nitrate is reduced in H to obtain a powd. mixt. of reduced Mo with unreduced thoria. The powder is formed into bars, sintered at about 2000° and drawn. Part of the Th oxide is reduced by the Mo.

Composition for radio bulb filaments, etc., of high electron and light emission. C. A. LAISE. U. S. 1,569,095, Jan. 12. An alloy of W, Th and V has finely divided particles of Yt oxide interspersed through it and comprises W 90% or more, Th 0.5-5.0%, V 0.5% or less and Yt oxide 0.55-2.50%.

Absorption and diffusion photometer. A. VERNES, R. BRICQ, M. L. A. JOBIN and G. G. J. YVON. U. S. 1,569,342, Jan. 12.

X-ray apparatus. R. POHL. Brit. 233,837, March 28, 1924.

The science museum, South Kensington, London. H. W. DICKINSON. *Mech. Eng.* 48, 104-8(1926). E. J. C.

Nuclear numbers. DIAZ DE BARROS. *Compt. rend.* 181, 719-22(1925).—The following 2 properties of at. wts. are presented without comment. (1). The nuclear no. of an element is defined as $N = (M - N)/2$, M and N being the at. wt. and the at. no., resp. The elements and their nuclear no. are arranged in a Mendelyeev-Moseley table of 16 vertical columns, each of which contains 5 spaces. Each space contains 1 and sometimes 2 or 3 elements, e. g., (Fe, Co, Ni). This table of nuclear nos. is shown to be almost identical with a table contg. the totals of the periodic series of Mayer, which express certain relations between the configurations assumed by floating magnets in a magnetic field. (2). If the spaces of a vertical column in the above table are numbered from 1 to 5, and if α represents the no. of the space occupied by an element, then, for the elements in the same column, $M_\alpha = 2N_\alpha + N_{\alpha-1}$. Substituting for N its value as defined above gives $M_5 = 2N_5 + (9N_4/2) + (N_3/4) + (N_2/8) + (N_1/16)$; $M_4 = 2N_4 + (N_3/2) + (N_2/4) + (N_1/8)$; and similarly for the other elements of the same column. As an application of this relation between the at. wt. and the at. no. there are calcd. the values of certain controverted at. wts., and those of the at. wts. of the undiscovered elements of known at. no. R. H. LOMBARD

The triumph of carbon. ALFRED STOCK. *Naturwissenschaften* 13, 1000-3(1925).—The singular position of C among the elements is discussed. B. J. C. VAN DER HOEVEN

Note on the hypothesis of molecular aggregation. Y. ROCARD. *J. phys. radium* 6, 198-201(1925).—Viscosity data do not agree with an expression deduced from the mol. aggregation theory. When van der Waals' $RT/v-b$ is modified by taking into account the general facts of cohesion and internal pressures, a satisfactory equation of state is evolved. H. R. MOORE

Molal volume and molal refraction in liquid mixtures. W. HERZ. *Z. anorg. allgem. Chem.* 149, 270-2(1925).—Previous calcns. (C. A. 19, 1515) have shown the

ratio of molar refractivity to molar vol. at zero abs. (MR/V_0) for "common" org. compds. to be about 3. (The calcd. values vary between 2.5 and 3.5.) The same ratio is now calcd. for mixts. of org. liquids. The molar refractivity is evaluated from existing refractivity and d. data with the mean mol. wt. as calcd. by the rule of mixts. The ds. at zero abs. of the mixts. are calcd. from existing data in a similar manner. The generalization previously made for the individual liquids holds for the following mixts.: benzene-acetone, benzene-acetic acid and aniline-ethyl alcohol. The relationship ($V_0 P_k/T_k = 5.7$, where $T_k =$ abs. crit. temp., $P_k =$ crit. pressure in atm., and $V_0 =$ mol. vol. at zero abs., holds for mixts. of ether-benzene and ether-diethylamine.

R. L. DODGE

A new method for the determination of molecular weights. G. RASTELLI *Gazz. chim. ital.* **55**, 552-4(1925).—The vapor tension of 2 solns. of different substances in the same solvent but of the same concn. are proportional to the mol. wt. of the dissolved substances. By the use of this principle mol. wts. are detd. in an app. the construction and use of which are fully illustrated and described.

E. J. WITZEMANN

Molecular weight determination in mixed solution media. C. DRUCKER. *Z. Elektrochem.* **31**, 409-12(1925); cf. *C. A.* **17**, 3825.—A study of the system CS_2 -MeOH with the solutes diphenylamine, azobenzene, naphthalene and acetanilide has shown the invalidity of Nernst's theory of mixed solvents. The vapor compn. is changed by different amts. and in different directions depending on the substance added. It is closely related to the effect of the added substance on the critical mixing temp.

H. R. MOORE

The molecular volumes of salts at their melting points. RICHARD LORENZ AND W. HERZ. *Z. anorg. allgem. Chem.* **145**, 88-94(1925).—The mol. vols. of salts at their m. ps. have been detd. and tabulated for 49 salts, mostly halides. In general, the ratio of the mol. vols. of the crystd. salts at room temp. to the mol. vols. at the m. p. is const. and equal to 0.8. $AlCl_3$ and AgI are exceptions. There is a linear relation between the mol. vols. of the different halides of the same alkali metal at the m. p. The mol. vol. of the alkali halides increases with increasing wt. of either the metal or halide. The mol. vols. of the carbonates, sulfates and nitrates of the alkali metals at the m. p. and in the cryst. state increase with the at. wt. of the alkali metal.

A. W. KENNEY

The influence of crystal lattice spaces on molecular mobility and solidity. ADOLPH SMEKAL. *Physik. Z.* **26**, 707-12(1925).—Brief discussion of contemporary work in this field (cf. *Wien Akad. Anz.*, June 25, 1925).

W. H. STRAIN

Paracrystalline and stressed substances. FRIEDRICH RINNE. *Naturwissenschaften* **13**, 690-4(1925).—A review.

B. J. C. VAN DER HOEVEN

Structure of crystals. H. MARK. *Naturwissenschaften* **13**, 1042-5(1925); cf. *C. A.* **19**, 3424.—The mosaic structure of crystals (even the best-formed, optically perfect, large crystals usually are built up from small (10^{-4} cm.), almost identically orientated crystals) can be demonstrated by means of X-ray reflection expts. The intensity ratio of reflected and incident ray is generally larger than expected from Ewald-Darwin theory, the reflection image broadens noticeably at larger distances from the crystal, the intensity of reflection from different lattice planes is proportional to the square (Laue), rather than to the first power (Ewald) of the structural factor. Whereas the divergence of the reflected ray from an ideal crystal is about 5 seconds, it was found to be for a diamond sample 3 min.; from the distribution of blackening over the broadened lines (10 m. distance) the av. orientation of the subcrystals can be estd.; the max. error in orientation for normal diamond is about 2 min., for rock salt crystals up to 15 min.

B. J. C. VAN DER HOEVEN

Lattice arrangements in deformed metal crystals and crystal agglomerations. G. SACHS AND E. SCHIEBOLD. *Naturwissenschaften* **13**, 964-8(1925).—Photographs are given of Debye-Scherrer diagrams obtained under different angles from drawn Al wire and rolled Al sheet. The "texture" of the deformed metal, i. e., orientation of the constituent crystal particles, is discussed and results obtained are reviewed (Ettisch, Polanyi, *C. A.* **16**, 1063; Mark, *C. A.* **17**, 2208, 3264; Glocker, *C. A.* **19**, 2581). It is shown how a highly symmetrical texture can be obtained by pressing an Al cube in the direction of the different crystallographic axis.

B. J. C. VAN DER HOEVEN

X-ray investigations of palladium-silver alloys containing hydrogen. F. KRÜGER AND A. SACKLÓWSKI. *Ann. Physik* **78**, 72-82(1925).—The system Pd-Ag forms a continuous series of solid solns. X-ray measurements with a Bohlin-Seemann spectrograph show that the lattice const. of the solid solns. obey Vegard's rule of additivity. Pd and Pd-Ag alloys were saturated with H electrolytically. For pure Pd, the absorption is greatest, and it decreases regularly with increasing Ag content to 70 mol. %.

when H_2 is no longer absorbed. The lattice const. of pure Pd and of Pd-Ag is increased by saturation with H_2 to a const. value of 4.00 A. U. ($Pd = 3.89$), regardless of the composition of the alloy. This value of the lattice const. is that of the Pd-Ag alloy contg. 70% Ag, which no longer absorbs H_2 . The H_2 is probably in the interstices of the space lattice. There is no evidence of a new compd. R. J. HAVIGHURST

X-ray interference in mixed crystals. M. v. LAUE. *Ann. Physik* 78, 167-76 (1925).—Tammann's theory (*C. A.* 14, 671) of a regular distribution of solute ats. over the lattice points in a mixed crystal is not confirmed by X-ray measurements on solid solns. If there is a regular arrangement of solute ats., new lines should appear on the X-ray diffraction patterns. Tammann claims that a slight departure from complete regularity in the substitution of solute ats. for solvent ats. would cause the intensity of these new diffraction lines to become too small for measurement. The author calcs. the structure factor for the intensity of these reflections, and shows that even if no more than one-half of the solute ats. in a 50 mol. % solid soln. are regularly distributed in the space lattice, the new diffraction lines should be observable. The fact that X-ray analysis of solid solns. has failed to find these new lines indicates that the solute ats. are distributed at random over the lattice points. R. J. HAVIGHURST

Elasticity. A. SCHÖR. *Gummi-Ztg.* 40, 624-5 (1925).—To obviate the confusion and errors current in the meaning and significance of elasticity in a material, it is proposed to define elasticity as the ratio: *work recovered/work expended*, when a material is subjected to deformation. For *complete elasticity* the ratio is 1, and for *complete plasticity* it is 0. Neither limit is reached, however, by any material. This definition does not involve the extent of the deformation, the latter depending merely on the sp resistance against deformation. Deformation thus presupposes elasticity but is not a measure of it. On this basis rubber is a relatively inelastic material, compared, e. g., with steel. Elasticity as thus defined can be measured directly by the relative height of rebound of a falling body. C. C. DAVIS

Pyrophorous bismuth. L. VANINO AND A. MENZEL. *Z. anorg. allgem. Chem.* 149, 18-20 (1925).—Pyrophorous Bi is a black powder which oxidizes spontaneously at room temp. in the presence of air. It is prepd. by reducing basic $Bi(NO_3)_3$ with H_2 . H. R. MOORE

The composition of a precipitated aluminium hydroxide. JITARŌ SHIDEI. *Mem. Coll. Sci. Kyoto Imp. Univ.* 9A, 42-73 (1924).—(In English.) Expts. have been made to det. whether pptd. Al hydroxide kept in H_2O for a long time undergoes such a transformation as to bring about a change in its compn. The method employed was to measure its vapor tension and also to observe the mode of its dehydration in a vacuum at const. temp. The manometer used consisted of 2 glass cylinders 8 cm. in length and 5 cm. in diam. connected with each other by 2 Y-tubes, the one at the lower ends extending to a Hg supply and the one at the upper ends connecting with a vacuum pump. A micrometer screw through the top of each cylinder was adjusted with the aid of a telescope to contact with the Hg. The difference in levels of the Hg (vapor tension) could be read with an accuracy of 0.01 mm. The Al hydroxide was pptd. with NH_4OH from a soln. of alum, then dissolved in HCl and again pptd. with NH_4OH . The ppt. was thoroughly washed by decantation and finally freed from electrolytes by a hot dialysis. After being kept for 17 months under H_2O , the ppt. was subjected to the expts. carried out at 30°. The dehydration of the hydroxide contg. 5.639 H_2O per mol. of Al_2O_3 was continuous, without any sudden change in its velocity in a vacuum at least until the compn. had been reduced to 2.494 H_2O per mol. of Al_2O_3 . Further dehydration would have taken a very long time and was not continued. The increase of the pressure of the aq. vapor from the hydroxide placed in a vacuum was rapid at first and then gradual, taking a long time to reach equil. The vapor tensions decreased continuously with the diminution of the H_2O content of the substance. S. concluded that the pptd. Al hydroxide which was kept for 17 months under H_2O still remained as an oxide absorbing H_2O , not as a definite hydrate. H. M. McLAUGHLIN

Uranyl oxalate (reply to M. Colani). A. RAYNAUD. *Bull. soc. chim.* 37, 1375-6 (1925); cf. Colani, *C. A.* 19, 3183.—R. points out that the results of work published later than that to which Colani refers agree perfectly with those of Ebelen, Courtois and Colani. The conclusions from this later work were: (1) uranyl oxalate crystd. with 3 mol. H_2O , loses 2 of them when heated to 100-120° for 10 hrs. The 3rd is lost only by heating to 250° for 4 hrs. (2) The anhyd. salt is hygroscopic and quickly regains 2 mols. H_2O but the 3rd is absorbed very slowly. P. B. PLACE

Hydroxides of aluminium and of trivalent iron. F. HABER. *Naturwissenschaften* 13, 1007-12 (1925).—Report on work partly published previously (*C. A.* 16, 3243; Boehm, *C. A.* 18, 1406). All mineral cryst. forms of Al and Fe hydroxides have one

metal at. to the mol. $(\text{Al}(\text{OH})_3, \text{AlO}_2\text{H}, \text{FeO}_2\text{H})$. It follows from the low heat of formation of $\text{Fe}(\text{OH})_3$ as compared with that of $\text{Al}(\text{OH})_3$ that an iron hydroxide of this compn. has too high a $p_{\text{H}_2\text{O}}$ to be stable. Data are given on the temp. at which a noticeable water loss occurs for several minerals. This temp. is always higher for the hydroxide of the α series: bauxite 300° , diasporite 420° , hydrargillite 200° . The compds. of the γ series are the less stable ones; at high temps. (above 400°) they are converted into α forms. Very likely an artificial hydroxide $\text{Al}_2\text{O}_3\text{H}_4$ exists, this is in agreement with Willstätter's observations. The mechanism and energetics of the hydration are quant. discussed.

B. J. C. VAN DER HOEVEN

The effects of dyes upon the crystallization of calcium carbonate. V. KOHL-SCHÜTTER AND CARLA EGG. *Helvetica Chim. Acta* 8, 697-703(1925). (In German.) Cf. C. A. 20, 132.—In order to det. the mechanism of the formation of "somatoid" forms (C. A. 20, 131), K. and E. study the crystn. of CaCO_3 in the presence of Congo red, gallacetophenone, ponceau, alizarin, Bismark brown, eosin, crystal violet, fuchsin, tropaeolin and chrysoidine. No direct relationship exists between the observed effects and the physical or chem. properties of the dyes. However those dyes seem to have an effect which either alone or in solns. with Ca ions can be observed with the ultra-microscope. The regular growth of the lattice of both calcite and aragonite is repressed probably because of an adsorbed film on the crystal faces which mechanically passivifies them. Excellent half-tone reproductions of the crystal forms are included.

GEORGE L. CLARK

The conditions and fundamentals of the formation of somatoid forms. V. KOHL-SCHÜTTER, M. BORTEL'SKY AND CARLA EGG. *Helvetica Chim. Acta* 8, 703-23(1925). (In German.)—A more detailed treatment of C. A. 20, 131, as to production of the disk-shaped, a - and b -forms. The crystn. process of the a -form from calcite seeds is influenced by the changed diffusion in the colloidal hull zone and the mechanical action of the limiting layers, but it det. finally the development form of the substance. In the formation of the b -form the growth is more directly dependent upon the colloidal substance from the beginning. The a -form is studied as decompn. in air streams of bicarbonate solns. contg. varying amts. of Co salts, the slow neutralization of bicarbonate solns. with NH_3 , the decompn. of $\text{Ca}(\text{HCO}_3)_2$ solns. in free atm., decompn. of hydrate crystals, decompn. of $\text{CaCO}_3 \cdot \text{Na}_2\text{CO}_3 \cdot 5\text{H}_2\text{O}$ (Gay-Lussit) crystals, and for other cases.

GEORGE L. CLARK

The compression and decomposition of nitric oxide. R. BRINER, H. BIEDERMANN AND A. ROTHER. *Helvetica Chim. Acta* 8, 923-8(1925). (In French.)—The compressibilities of NO are measured in the temp. interval from -80° to $+10^\circ$ and up to 160 atm. and the isotherms plotted in the usual way, p against v where p is fractionally related to $p_0 v_0 = 1$ (where p_0 is unit pressure and v_0 is the corresponding vol. at the temp. considered). When compared with the isotherms of N_2 , O_2 , C_2H_4 and CO_2 , there is no indication of an abnormal polymerization of NO. Decompn. with formation of N_2O_3 is studied at 700 atm.

GEORGE L. CLARK

Investigation of ozone. HANS V. WARTENBERG AND GEORG V. PODJASKI. *Z. anorg. allgem. Chem.* 148, 391-6(1925).—Phys. methods are not satisfactory for detg. small quantities of O_3 in the air (0.1 to 1.0 mg./cu.m.). Small quantities of KI in soln. are sufficient completely to remove all traces of O_3 from air bubbled through it however rapidly. The authors tried to use this as a basis for a colorimetric detn., but found it unsatisfactory except in daylight. The following method was found to be reliable. The air contg. O_3 is drawn through a tube contg. about 2.5 cc. KI soln. (2 g. in 100 g. H_2O) at a rate of 1 to 2 l. in 5 to 15 min. Then to the soln. is added 1 drop 2% HCl soln., 1 drop of starch soln. and a small quantity of NaHCO_3 and the liberated I is titrated with very weak As_2O_3 soln. (about 0.0004 N). This method was found to be reliable, the O_3 concn. which could be detd. being independent of current velocity and vol. of air. O_3 was found to be more sol. in org. solvents than in H_2O and reaches a higher concn. in these than in air. Thus when air contg. 101 g./cu.m. is passed through vinegar a concn. of 249 g./cu.m. is reached at 18.2° , 157 g./cu.m. at 30.2° and 138 at 38.8° . Figures are given for dichloroacetic acid, Ac_2O , EtCO_2H (EtCO_2) $_2\text{O}$ and CCl_4 . Solns. in these solvents do not decompose as quickly as H_2O solns. H. S.

Densities and inner friction of glycerol solutions. W. HERZ AND A. WEGNER. *Z. deut. Oel-Fett-Ind.* 45, 401-2(1925); cf. C. A. 19, 1519.—H. and W. report results of d. detns. of the higher concns. of glycerol and calc. the inner friction from Ostwald's formula $st/\sigma\tau$ in which s and σ denote the densities of two substances and t and τ the times of flow from a capillary pipet. The abs. inner friction is calcd. by multiplying the relative friction by the H_2O value.

P. ESCHER

The distillation of amalgams. A. MIETHE AND H. STAMMREICH. *Z. anorg. all-*

gem. Chem. **149**, 263-9(1925).—Pb, Zn, Cd and Na were separately dissolved in Hg in the proportions 1:100, 1:500, 1:2000, 1:5000 and 1:10,000. The amalgams were then distd. at various pressures from 26 mm. to 1 mm. Particular care was taken in the construction of the distn. app. to prevent spattering of the amalgam and mech. contamination of the distillate. The amalgam was heated uniformly to avoid bumping, the distn. furnace temp. being maintained at 300°. The distn. was stopped when 98% of the Hg had been distd. The residue was analyzed by the usual analytical methods. Except with the Cd amalgam, the loss of base metal from the distn. flask never exceeded 1/10 mg. per 200 g. amalgam. The vapor pressure of Cd at 210-110° is sufficient to account for the loss observed in this case. There is no amalgam of the above metals that has a vapor pressure very close to that of pure Hg. Tiede's expts. with Au amalgam (cf. *C. A.* **19**, 3209) were repeated, with particular care to avoid transfer of amalgam by spattering. No Au could be detected in the distillate. The analytical method would have detected 1/1,000,000 mg. of Au. By a single distn. the concn. of Au in the distillate was reduced to at least 1/3,000,000 of the concn. in the original amalgam. Colloidal Au dissolved in Hg gave the same results.

R. L. DODGE

Pressure-temperature charts. Extended ranges. GEORGE CALINGAERT AND D. S. DAVIS. *Ind. Eng. Chem.* **17**, 1287-9(1925); cf. *C. A.* **19**, 2430.—An extension of Cox's empirical method (*C. A.* **17**, 2359) to much higher temps. than reported previously. Graphs are shown for normal paraffin hydrocarbon series, C_6H_6 series, alcohol series, silicon hydrides and a metal series.

W. C. EBAUGH

Some remarks on viscosity measurements. J. DUCLAUX AND J. ÉRREIRA. *J. phys. radium* **6**, 202-4(1925).—Ostwald's viscometer is not suitable for liquids of high fluidity. When the capillary is replaced by a porous clay cup, detns. are made rapidly.

H. R. MOORE

Dehydration of alcohol by purification in the presence of benzene. J. BARBAUDY. *Compt. rend.* **181**, 911-3(1925).—Young (*J. Chem. Soc.* **81**, 707(1902)) detd. the compn. of the water-alc.-benzene eutectic and showed how abs. EtOH could be prepd. B., on studying boiling and compns. of vapor of this system attempts to explain in part the principle of Y.'s method. B. gives a phase diagram and traces the changes in concn. starting with a given water-alc.- C_6H_6 mixt. The effect of adding C_6H_6 to an EtOH- H_2O mixt. is discussed.

D. H. POWERS

Influence of adsorption on the color of sols and of precipitates. N. R. DHAR. *J. Phys. Chem.* **29**, 1394-9(1925).—Several cases have been reported where the color of the positively charged sol is different from that of the negatively charged sol of the same substance or from that of the electrolyte from which the sol is prepd. The color of freshly pptd. MnO_2 , $Fe(OH)_3$, $Co(OH)_2$ and $Cu(OH)_2$ depends a great deal on the nature of the substance adsorbed by the ppts. in the course of their formation. The blue color of adsorption compds. of I_2 with starch, dextrin, cholic acid, basic La acetate, etc., seems to be due to the existence of I_2 in the colloidal condition in such compds.

H. M. McLAUGHLIN

Adsorption of acids by filter paper. S. G. MOKRUSHIN. *Kolloid-Z.* **37**, 144-6(1925).—In explanation of the const. k in Holmgren's equation and of z in Schmidt's equation, $z = c(R^2 - r^2)/r^2$ (cf. *C. A.* **8**, 642), M. has assumed a monomol. layer of acid on the capillary walls of the filter paper in agreement with Langmuir's adsorption theory. The const. was independent of the degree of dissociation, i. e., acid mols. were adsorbed (cf. Schilow and Lepin, *C. A.* **14**, 1775). Expts. with HCl, HNO_3 , H_2SO_4 , $H_2C_2O_4$ and tartaric in concns. from 0.25 M to $M/1024$ supported this theory.

H. M. McLAUGHLIN

Absorption of iodine by casein. F. LIEBMAN AND D. LÁSZLO. *Biochem. Z.* **159**, 110-25(1925).—Casein (Na salt) is treated with KI_3 and dialyzed free of I . AcOH then is added to ppt. the iodinated casein. The amt. of I taken up by casein varies with the amt. of I used, much being adsorbed. The adsorption is not attributed to the presence of any one amino acid.

W. D. L.

Adsorption of iodine by starch. E. ANGELESCU AND J. MIRESCU. *Bul. soc. române științe* **27**, 59-64(1924).—Study of the adsorption by maize starch of I in 2, 5, 10 and 15% KI solns. showed that with 1 solns. having an initial concn. of 1% or over it takes place according to the exponential formula $C_a = K \cdot C^p$ in which C_a is the I adsorbed by 1 g. starch, C the concn. of I remaining in soln. after adsorption, and K and p are consts. K and p are independent of the concn. of KI . KI itself is not adsorbed by the starch. The equil. formula for hydrolysis, $x/(a-x)(n-x) = K$ does not hold.

A. PAPINEAU-COUTURE

The bases of the static and dynamic exclusion theory. D. REICHSTEIN. *Z.*

Elektrochem **31**, 593-613(1925).—An extended exposition of the hypothesis that the total no. of mols. adsorbed on any surface is const. In the case that the rate of absorption is infinite compared with the rate of reaction on the surface, a surface film should be formed which accounts for passivity and the related phenomena of catalytic poisoning and galvanic polarization. If the concn. of the adsorbed material in the adsorbed layer is proportional to its concn. in the outer phase, the hypothesis of const. sum leads to R's well-known equation for the absorption isotherm. In certain cases the rate of diffusion into the solid must be taken into account; if so a general theory can be given for electrode potentials, chem. reactions on surfaces, thermal cond. of surfaces and viscosity.

F. R. B.

The composition of soap films. MARY EVELYN LAING. *Proc. Roy. Soc. (London)* **109A**, 28-34(1925).—Criticism of previous work on the chemistry of soap films is based on the possibility of reaction between the film and the O_2 and CO_2 of the air. The films in this study were produced by shaking a pure soap soln. in an atm. of pure N_2 . The foam was sepd. from the liquid and analyses were made by chem., and by elec. cond., and refractive index methods. There is an increase of concn. of soap in the film, and the film contains not free fatty acid, but an acid sodium oleate, contg. 0.61 mol. oleic acid to 1 mol. Na oleate, probably hydrated. This result is in accordance with the suggestion that the black spot in soap films is due to the actual contact of the 2 adsorbed layers. The stability of soap films is much more readily understood if they are made of colloidal material, like the acid soap, rather than of a pure liquid, such as oleic acid.

A. W. KENNEY

Brownian movement of very large particles. JITSUSABURO SAMESHIMA. *Nagaoka Anniv. Vol. 1925*, 203-12; *Japan J. Physics* **4**, 12A - A suspension of large granules of mastic was made by diffusion of EtOH soln. of mastic into 36% aq. soln. of $CO(NH_2)_2$. The suspension was put in a hemocytometer of Thomas and the movements of the particles were observed with an ordinary microscope projecting on a screen of translucent paper. The diams. of the granules varied from 0.0002 to 0.002 cm. The Avogadro no. was calcd. by means of Einstein's formula: $N = 63.6 \times 10^{24}$. The Brownian movements of rotation were observed upon a particle of 0.001039 cm. diam. and it was shown that the Einstein formula for the rotational Brownian movement can probably be applied to this case.

C. J. WEST

The Brownian movement of rotation. FRANCIS PERRIN. *Compt. rend.* **181**, 514-6 (1925).—A mathematical paper.

MARIE FARNSWORTH

Peptization. A. V. SLATER. *J. Soc. Chem. Ind.* **44**, 499-506T(1925); 56 references. —A general theory of peptization is presented as follows. The definition accepted is deduced from Graham's use of the term. "True peptization is the transformation of a gel to a sol by the addn. of a small quantity of a dispersing agent." Increased elec. charge and lowered interface tension are not sufficient in themselves to cause actual dispersion. Chem. action between the colloid and the peptizer is essential. A substance in gel form whose particles are not above colloidal dimensions can be peptized. The peptizer should be easily adsorbed by reason of primary or secondary valence forces and one part of the peptizer mol. should unite with a part of the colloid mol. to form a non-ionized mol. This keeps the concn. of the flocculating ion low. The colloid particles are drawn into soln. by the soln. pressure exerted by the peptizer. In general, substances capable of forming sol. compds. with the colloid in high concn. will peptize easily at low concns. Raising the temp. and increasing the pressure enable some substances to peptize a colloid, which at lower temps. and pressures are unable to overcome the cohesion of the colloid. Peptizations are classified: (1) "peptization" by protection prior to formation of the colloid substance, e. g., adding KOH to a soln. of $CuCl_2$ contg. sugar; (2) reversible coagulation; (3) peptization by dissoln. of non-colloidal substance, e. g., $BaSO_4$ and $MgCO_3$ treated with $SeOCl_2$. True peptizations come only under (2).

H. M. McLAUGHLIN

Organophile colloids. G. S. WHITBY. *Can. Chem. Met.* **9**, 265-7(1925).—The best known organophile colloids are the cellulose esters and rubber. W. brings out the fact that with all the common classes of org. compds. those that dissolve the cellulose esters do not swell or dissolve rubber at all, or do so very slightly and *vice versa*. There are very few exceptions to this generalization. Furthermore, the lower members of any homologous series are the better solvents for cellulose esters, the higher members for rubber. W. considers the most satisfactory explanation of this lies in the polarity of the compds. concerned. Cellulose nitrate and acetate are polar substances and in general imbibe and yield sols and gels with polar org. substances, while rubber is non-polar and in general imbibes most freely non-polar liquids. E. g., AcH is a solvent for cellulose acetate, but produces scarcely any swelling with rubber. On going up the

aldehyde series to heptaldehyde, however, the position is reversed. This aldehyde is a non-solvent for cellulose acetate, but dissolves raw rubber. Presumably, increase in the size of the hydrocarbon residue from CH_3 to C_6H_{11} has reduced the polarity of the aldehyde, so that it no longer attaches itself readily to the polar cellulose acetate, but does to the non-polar rubber.

E. G. R. ARDAGH

The applications of colloids to electrotechnology and radiotechnology. P. HARMARDINQUER. *La nature* [ii] 53, 329-33(1925).—An illustrated description of the properties of colloidal solns., dealing particularly with the *colloidal commutator*.

C. C. DAVIS

Colloidal manganese oxide. ANASTASIE ANARGYROS. *Compt. rend.* 181, 419-21 (1925); cf. Witzemann, *C. A.* 9, 1567.—The method of prepn. was based on that of Deiss (cf. *C. A.* 4, 1583). Different reducing agents such as glycerol and HCHO gave unstable colloids. By mixing the KMnO_4 soln. with a stabilizing agent (Na protalbate) and then adding 1 of the reducing agents, stable colloidal solns. of deep brown color were obtained. Satisfactory results were obtained with solns. of NaAsO_2 which served at the same time as protecting and reducing agent. The analysis of 3 samples of the colloid corresponded to Mn_2O_3 .

H. M. McLAUGHLIN

Mechanism of the Liesegang phenomenon. A. STROPOR. *Bul. chim. soc. romând stiinte* 27, 51-8(1924).—Under the microscope Liesegang rings obtained with very thin films of gelatin are seen to consist of series of fine bands, those in the middle of a given ring being heavier and better defined than those at the edges. S. puts forth a theory explaining the mechanism of their formation based on the difference between the rates of diffusion of the pptg. ions, and on the variation in viscosity of the gelatinous mass, which is due mainly to the heat of the reaction by which the ppt. is formed and to a slight extent to the H_2O introduced by adding the pptg. soln. He shows how this results in a discontinuous, but recurring, reaction between the ions.

A. PAPINEAU-COUTURE

The behavior of silica gel towards alkalis and salts in aqueous solution. W. A. PATRICK AND E. H. BARCLAY. *J. Phys. Chem.* 29, 1400-5(1925).—The removal of NaOH from aq. soln. by silica gel and the subsequent replacement of the "adsorbed" Na^+ by Ag^+ , Cu^{++} and Fe^{+++} have been studied by: (1) shaking at 20° a known wt. (about 5 g.) of silica gel of known (8-11%) H_2O content (cf. *C. A.* 14, 1776) with solns. of NaOH of known vol. and known, but varying, concns. for sufficient time to reach equil.; (2) after rinsing the gel with distd. H_2O it was similarly treated with solns. of AgNO_3 (0.1 *M*), $\text{Cu}(\text{NO}_3)_2$ (0.1036 *M*) and $\text{Fe}_2(\text{SO}_4)_3$ (0.178 *M*). NaOH was removed from soln. by silica gel to a greater extent the greater the concn. of alkali in the surrounding soln. Na^+ ions were replaced by other ions in accordance with stoichiometric laws. The removal of NaOH could be accounted for by Freundlich's adsorption equation. It is proposed to subdivide adsorption phenomena into 3 classes: (1) chem.; (2) mol. layer; (3) capillary.

H. M. McLAUGHLIN

Jelly strength of pectin jells. GEO. L. BAKER. *Ind. Eng. Chem.* 18, 89-93(1926).—The new *jelly-strength tester* consists of a piston actuated by air pressure produced hydrostatically and measured by a connected manometer. Considering quantity of acid, the pectin jelly optima follow Tarr's 1:2:3 ratio for H_2SO_4 , tartaric and citric acids, the relative jelly strengths varying, as also do the p_H points of the optima. With 1% pectin, jelly was strongest with 69.44% sugar; with 2% pectin, with 66.66% sugar. At a certain p_H , a definite pectin-sugar ratio is essential for max. jelly strength. The optimum pectin concn. is 0.97%, beyond which clouding and poor texture appear. The injury to jelly strength caused by boiling while acid, is inhibited on addn. of sugar. Increased concn. of pectin and lower temp. of boiling both increase jelly strength.

JEROME ALEXANDER

The kinetics of swelling and shrinking of gels. II. S. LIEPATOV. *Kolloid-Z.* 37, 146-50(1925); cf. *C. A.* 19, 2436.—The velocity of the swelling was a function of the thickness of the gel. The amt. of surface of the gel and its wt. played a secondary roll. The temp. conditions, the presence of acids and the thickness exerted a strong influence on the velocity. The principle of the mobility of H_2O in colloids first proposed by van Bemelen could be used for explanation of the swelling phenomena. Swelling seems to be the first step of soln.—transformation of the gel into sol. H. M. MCL.

Is there a relationship between solubility and the stability of crystal-water binding? Tests on salts of aromatic sulfonic acids. FRITZ EPHRAIM AND ERNST SEGER. *Helvetica Chim. Acta* 8, 724-39(1925). (In German).—It would be predicted that those salts which hold mols. of H_2O with strongest bonds, so that a central metal atom would be surrounded by a hull of water, would be most sol. in H_2O . Of the hexahydrate salts of Cu , Cd , Mn , Zn , Ni , Mg and Co with benzenesulfonic and 2-naphthalenesulfonic

acids tested in the order of decreasing soly., however, it is established that the most difficultly sol. salts hold the crystal water most firmly. The salts of 1-naphthalene-sulfonic acid are most easily sol. which are least so in the case of the 2-acid. The influence of the at. vol. of the central metal upon the stabilizing NH_3 complexes is not observed with these closely related hydrates in which both cation and anion are concerned in a complicated fashion. Detailed directions are given for prepn. of the salts, many here produced for the first time.

GEORGE L. CLARK

The influence of electrolytes on the solubilities of some organic acids. N. A. VAYNIK, M. P. JAIN AND DINA NATH. *Quart. J. Indian Chem. Soc.* 2, 115-28(1925); cf. *C. A.* 8, 2292.—The effects were studied of small concns. (to about 0.01 *M*) of the chlorides and nitrates of NH_4 , Na, K, Ca, Sr and Ba and of the sulfates of NH_4 , Na and K on the solubilities at various temps. of the 3 isomeric nitrobenzoic acids and of $p\text{-NH}_2\text{C}_6\text{H}_4\text{SO}_3\text{H}$ and $p\text{-OHC}_6\text{H}_4\text{SO}_3\text{H}$. The solubilities of the 3 nitrobenzoic acids in H_2O at 25°, 35° and 42° were found to be as follows (in g./100 g. H_2O): *o*-acid, 0.750, 1.30, 2.28; *m*-acid, 0.344, 0.418, 0.515; *p*-acid, 0.028, 0.025, 0.022. The solubilities of $p\text{-NH}_2\text{C}_6\text{H}_4\text{SO}_3\text{H}$ at 20°, 30° and 40° were 1.00, 1.45 and 1.94. The conclusions drawn were as follows: (1) with increase of temp. the influence of alkali nitrates and chlorides in increasing or decreasing the solubilities of the acids decreases, but that of the alk. earth nitrates and chlorides and of the alkali sulfates increases; (2) with increase in concn. of the salts used, the solubilities of the *o*- and *p*-acids passes through a max., while that of the *m*-acid decreases first rapidly and then slowly and regularly; (3) the effect of cations (either to increase or decrease the solubilities) increases in the order NH_4 , Na, K, Ca, Sr, Ba (*i. e.*, in the order of their at. wts.); (4) the effect of anions increases in the order SO_4 , Cl, NO_3 . The effect of small quantities of salts was surprisingly great. at 35° the relative soly. (pure H_2O = 100) of *p*-nitrobenzoic acid in 0.0008 *M* $\text{Ba}(\text{NO}_3)_2$ was 152 and of *m*-nitrobenzoic acid in 0.0012 *M* $\text{Sr}(\text{NO}_3)_2$ was 56.

DONALD W. MACARDLE

The relationship of salts in dilute aqueous solution as determined by their influence on the critical solution temperature of the system, phenol-water. J. H. CARRINGTON, L. R. HICKSON AND WM. H. PATTERSON. *J. Chem. Soc.* 127, 2544-9(1925).—The investigation of Duckett and Patterson (cf. *C. A.* 19, 1519) on the elevation of the crit. soln. temp. of the system, $\text{PhOH-H}_2\text{O}$, due to the addn. of a salt sol. only in the aq. phase is continued. When hydrolysis and complex formation are absent, the elevation, e , for a mixt. (36.0-36.1% PhOH) is nearly proportional to the concn. C (g. mols. solute per 1000 g. total mixt.). When hydrolysis occurs, there is a lowering. The mol. lowering, ($-E = -e/C$) becomes greater with increasing concn.; it would remain const. if the lowering were due to soly. of the salt in both of the phases. Anions and cations may be arranged qual. in order of diminishing e : SO_4 , hydrogen tartrate, Cl, Br, BrO_3 , NO_3 = 1, ClO_3 , HCOO ; and Ni, Mg, Cd, Co = Ba = Sr = Ca, Zn, Cu, Be, Pb, Na, Li, K, NH_4 , H. The effect of the anion is in general greater than that of the cation. Definite values cannot be attributed to the ions since the value is modified by the other ion in the compd. The effect in general decreases with increasing at. wt. of the elements in the various groups of the periodic system, the first member being out of place. The relation, $e = aC^b$ is found to hold, where b is a const. characteristic of the $\text{PhOH-H}_2\text{O}$ (= 0.83-0.87) and a is a sp. const. of the salt. This equation holds also for salts which are sol. in both phases but b has a different value. D. S. V.

Vanadium oxytrichloride as a solvent. F. E. BROWN AND J. E. SNYDER. *J. Am. Chem. Soc.* 47, 2671-5(1925).—The solubilities of about 125 substances in pure VOCl_3 were tested. Of these (1) nearly all inorg. compds. were insol.; (2) most non-metals were sol.; (3) metals were unaffected; (4) all of the org. compds. either dissolved, reacted or both; (5) org. liquids were miscible in all proportions; (6) liquid aldehydes reacted vigorously. The soly. of S was detd. quant. for temps. between 0° and 65°.

H. M. McLAUGHLIN

Solubility experiments with boiler metals and the determination of the dissolved metal. K. K. JÄRVINEN. *Z. Nahr. Genussm.* 50, 221-5(1925).—Reproducible results were obtained. Sheets of metal, 0.05 to 0.1 cm. thick and 7 cm. square, were rolled up and placed in glass cylinders 2 to 3 cm. in diam. The liquid was added and the cylinders were placed in a bath of boiling H_2O for 3 hrs., evapd. H_2O being replaced. The dissolved metal was detd. colorimetrically in most cases. Tables are given showing the soly. of various metals and alloys in the following solns.: (1) 5% NaCl, (2) 1% HCl, (3) 400 g. sugar and 15 g. citric acid per l.

WILLIAM J. HUSA

The colorimetric dissociation constants of 3,5-dinitrocatechol and 4,6-dinitroresorcinol. F. C. LAXTON, E. B. R. PRIDEAUX AND WM. H. RADFORD. *J. Chem. Soc.* 127, 2499-2501(1925).— p_m (p_H of halfway change to yellow) is 3.25 for 3,5-dinitro-

catechol; p_{k2} (p_H of halfway change from yellow to reddish brown) is 10.39. For 2-nitroresorcinol, p_{k1} is very low; p_{k2} is 6.47. For 4,6-dinitroresorcinol, p_{k1} is 4.22.

B. H. CARROLL

Decomposition potentials and polarization of certain heavy metallic chlorides dissolved in anhydrous pyridine. R. B. MASON AND J. H. MATHEWS. *J. Phys. Chem.* **29**, 1379-93 (1925).—In a search for suitable reference electrodes for use in anhyd. C_5H_5N the decompn. potentials, total polarization and anode and cathode polarization e. m. f.'s against an amalgam of the metal under consideration were measured for increasing values of applied e. m. f. for the following salts in satd. anhyd. C_5H_5N soln.: $ZnCl_2$, $CdCl_2$, Cu_2Cl_2 , $CuCl_2$, $HgCl_2$, $PbCl_2$, $HgSO_4$. The rotating commutator method was employed for measuring the potential of the single electrodes. The Hg - Cd , $CdCl_2$ and Hg - Zn , $ZnCl_2$ reference electrodes were found to be the most satisfactory. The behavior of these 2 salts was very much the same as in aq. soln. $CuCl_2$ gave trouble on account of its low soly. and cond. and its behavior depended on its previous history. In the case of Cu_2Cl_2 a compl. formed at the anode obscured the issue. The solns. of $PbCl_2$, $HgCl_2$ and Cu_2Cl_2 acted as if there were present a depolarizer for small amts of Cl_2 .

R. S. GIBSON

Cryoscopic measurements with benzene. E. R. JONES AND C. R. BURY. *J. Chem. Soc.* **127**, 1947-51 (1925); cf. *C. A.* **19**, 2439.—The object of the work was to compare $PhNO_2$ and C_6H_6 as solvents for cryoscopy. The importance of control of the H_2O content of the C_6H_6 is emphasized and the use of Al_2O_3 for this purpose recommended. The use of Brown and Bury's formula (cf. *C. A.* **19**, 2439) instead of the van't Hoff formula is preferred at higher concns. Several solutes were tried and 66.95 was taken as the value of k in the B. and B. formula, corresponding to 29.53 cal. for the latent heat of fusion of C_6H_6 . No definite evidence was obtained for solvation. Substances tend to be abnormal in C_6H_6 more than in $PhNO_2$. Reproducibility is more difficult with C_6H_6 .

A. W. KENNEY

Molecular attraction and velocity of reactions. O. MAASS AND C. SIVERTZ. *J. Am. Chem. Soc.* **47**, 2883-91 (1925); cf. *C. A.* **19**, 766.—The velocity of reaction of propylene and HCl in the liquid state was detd. at 0° and 20° by methods similar to those used in the previous investigation. The main product of the reaction was isopropyl chloride, but a chlorohexane formed from a side reaction. The hydrogen halide acts as a catalyst though no ionization could be detected. The initial rate of reaction with HBr is about 200 times that with HCl . In the gaseous phase, no reaction was detected at room temp. in a period of 400 days. The absence of reaction in the gas phase shows that concn. alone does not det. the reaction rate, and it is suggested that the 3 forms of heat energy have different effects on the reaction rate. The kinetic energy of translation and of rotation of the mols. hinders the chem. combination, whereas the kinetic energy of vibration furthers it.

A. W. KENNEY

The velocity of decomposition of a few esters and its relation to the hydrogen-ion concentration. K. G. KARLSSON. *Z. anorg. allgem. Chem.* **145**, 1-57 (1925).—The velocities of sapon. of $AcOMe$, $AcOEt$ and monoacetin were detd. at 25° as a function of the H -ion concn. Care was taken to use highly purified materials, and expts. were conducted in the presence of varying amts. of HCl and of different salts, e. g., $AcONa$, $CaCl_2$, $BaCl_2$, $SrCl_2$, Na_2SO_4 , $NaCl$, etc. If it is assumed that the org. acid esters are amphoteric, giving both H and OH ions, it follows mathematically that if the log of the velocity const. is plotted against p_H , the curve should be symmetrical. The exptl. results indicate this to be the case, there being a sharply defined p_H of minimum velocity. The velocity const. is detd. chiefly by the p_H in the case of acid hydrolysis, and the alc. has little influence; but in alk. hydrolysis, the alc. plays a more important part. Neutral salts also exert a secondary action and increase somewhat the velocity of sapon. Assuming the org. acid esters to be amphoteric, it was possible to calc. the velocity const. except in the region of max. stability. Expts. were also conducted on sapon. of the ethyl benzenesulfonate. The soly. of this ester in pure H_2O was detd. as 0.00739 ± 0.00002 mole per l. at 25° . The soly. in solns. of $AcONa$ and other salts of different concns. was also detd. The rate of sapon. may be expressed by an equation having the form $dx/dt = K.C_E + K_2.C_E.C_{NaOH}$, where C_E denotes concn. of the ester, etc. The consts. detd. by the author are: $K = (6.46 \pm 0.08) \times 10^{-4}$; $K_2 = 0.0070$. It is evident that this hydrolysis has an entirely different mechanism from that of the esters first studied. Bibliography attached.

A. W. KENNEY

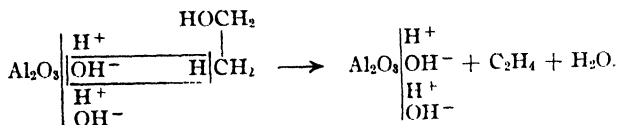

The action of silica on the sulfates of barium and magnesium. Mlle. GERMAINE MARCHAL. *Compt. rend.* **181**, 784-6 (1925); cf. *C. A.* **18**, 509.—The decompn. temps. of Ba and Mg sulfates are lowered by heating with an intimate admixt. of SiO_2 , the lowering being related to the heat liberated by the formation of the silicates of Ba and Mg from

the respective oxides. BaSO_4 alone breaks up at 1510° . With SiO_2 , gas is liberated at 1025° the pressure in cm. increasing as follows: 1100° , 2.3; 1190° , 5.0; 1240° , 8.2; 1270° , 12.0. MgSO_4 in a vacuum breaks at 880° and this is lowered to 680° by SiO_2 . Pressures are 700° , 0.6; 800° , 4.4; 900° , 15.0; 1000° , 61.5; 1012° , 76.0. P. B. PLACE

Reaction between potassium ferricyanide and morphine. R. A. BERETEVIDE. *Rev. facultad ciencias* 3, No. 2, 89–124 (1925).—The oxidation of morphine by $\text{K}_3\text{Fe}(\text{CN})_6$ is promoted by heat, excess $\text{K}_3\text{Fe}(\text{CN})_6$, alk. medium and pptn. of $\text{K}_3\text{Fe}(\text{CN})_6$ as soon as it is formed. The duration of contact between the 2 substances has no notable influence. The proportion in which they react is neither equi-mol nor const. M. J.

Comparative investigations on the activity of contact catalysts. III. The catalytic synthesis of water at elevated temperatures by metals and binary alloys of the eighth group of the periodic system that are inactive at room temperature. H. REMY AND H. GÖNNINGEN. *Z. anorg. allgem. Chem.* 149, 283–96 (1925); cf. *C. A.* 20, 5.—The lowest temp. at which some catalysts made of Ru, Fe, Co, Ni and alloys of Ir-Fe, Rh-Fe, Rh-Co, Os-Fe, Os-Co, Os-Ni, Ru-Fe, Ru-Co, Ru-Ni, Fe-Co, Ni-Fe, Ni-Co would initiate the reaction $2\text{H}_2 + \text{O}_2 \longrightarrow 2\text{H}_2\text{O}$ was measured. The temp. was detd. by gradually heating a sample of the catalyst material in a closed system filled with the gas mixt. The temp. of initial action was considered as that temp. at which the vol. increase of gas in the system, due to thermal expansion, gave place to a vol. decrease due to reaction. The activity temp. so measured was found to depend on rate of heating, form of catalyst, and previous treatment of the catalyst with H or O. No attempt was made to establish abs. values, but the relative activity temps. were evaluated in arbitrary units by conducting the expts. according to a uniform procedure. In general the Fe alloys were more active when previously treated with O, while the Ni alloys were more active after H treatment. Pure Fe, however, was more active after H treatment. R. L. DODGE

The mechanism of catalysis by aluminium oxide. M. C. BOSWELL AND H. M. DILWORTH. *J. Phys. Chem.* 29, 1489–1506 (1925).—Partially reduced oxides have an interior O content which may be drawn upon for the maintenance of the surface film. Al_2O_3 , in addn. to this interior O content (which, on account of the great stability of the oxide, is not available), has a surface layer of charged H^+ and OH^- . This film, in a state of tension due to the opposite charges, affords a remarkable protection for the underlying O. The great stability of the H_2O film is evidenced by the fact that it is still present after heating for 20 hrs. at 500° followed by 2 days' heating with a Meker burner. Another marked difference in the 2 types of catalysts (partially reduced oxides and Al oxide) is the fact that the former has a reduced metal layer over the unreduced oxide layer, and this reduced oxide layer probably carries charged H^+ and OH^- , whereas in Al_2O_3 the catalytic film of dissociated H_2O is wholly on the outside of each particle. The great stability of the H_2O film on the oxide indicates that the H^+ and OH^- are in alternate layers and completely envelope each oxide particle. The effect of heating the oxide to progressively higher temps. is progressively to remove the outer layers of the dissociated H_2O . Upon studying the reactions of $\text{C}_2\text{H}_5\text{OH}$ and Al_2O_3 , the authors conclude that the following constitution is most satisfactory:

The adsorption of electrolytes by Al_2O_3 also supports the theory of the layer of charged H^+ and OH^- on the surface of the oxide. The adsorption of C_2H_4 and C_2H_2 on Al_2O_3 for several partial pressures, and as a function of the temp. have been detd. When the water content of an Al_2O_3 catalyst is reduced, the activity is decreased. The catalyst has its max. activity at $350\text{--}400^\circ$. The catalytic action of Al_2O_3 on $\text{C}_2\text{H}_5\text{OH}$ at 350° has been studied in some detail. In addn. to formation of C_2H_4 , the 2 following reactions occur: (1) $2\text{C}_2\text{H}_4 \longrightarrow \text{C}_2\text{H}_6 + \text{C}_2\text{H}_2$, and (2) $\text{C}_2\text{H}_4 \longrightarrow 2\text{C} + 2\text{H}_2$. The C_2H_2 in (1) is polymerized and adsorbed on the Al_2O_3 together with the C formed in (2). C_2H_6 is formed entirely by reaction (1), there being none formed by a reaction of C_2H_2 with C_2H_4 . Al_2O_3 catalyzes the union of C_2H_4 and H_2O to give $\text{C}_2\text{H}_5\text{OH}$; $\text{C}_2\text{H}_2 + \text{H}_2$ with C_2H_4 . Al_2O_3 catalyzes the simultaneous dehydrogenation of C_2H_4 and $\text{H}_2\text{O} = \text{CH}_3\text{CHO}$ and $\text{H}_2 + \text{O} = \text{H}_2\text{O}$, the simultaneous dehydrogenation of C_2H_4 to C_2H_2 (which is adsorbed in a polymerized state on the catalyst), and the hydrogenation of C_2H_4 to C_2H_6 . The adsorptions of C_2H_4 at 24° and C_2H_2 at 25° on Al_2O_3 have been studied. Data on the adsorption of C_2H_4 on Al_2O_3 as a function of the temp. are included. J. H. PERRY

The poisoning of catalysts. F. B. MAXTED. *Ind. Chemist* 1, 449-52(1925).—

The criteria that enable one to predict the broad principles that govern the susceptibility of a system to poisoning can, in many cases, be defined. In general, a homogeneous system cannot be poisoned, while many heterogeneous systems can be. In this classification, a system is heterogeneous if the catalyst is a distinct phase. Purely chem. heterogeneous reactions like ordinary chem. reactions which differ only in that the former are cyclic, cannot be poisoned. Processes which are accelerated by general or non-specific adsorption, as by the action of the walls of the contg. vessel, cannot be poisoned. The preferential adsorption of a poison by a catalyst and the tenacity with which the adsorbed mols. are held, is briefly discussed. An infinitely small amt. of a poison cannot inhibit the activity of an infinitely great quantity of catalyst. The amt. of poison required to inhibit the activity of unit wt. of a catalyst to an equal degree varies with the state of subdivision of the catalyst. For catalytic hydrogenation in a liquid system the activity of a partially poisoned catalyst is linearly proportional to the concn. of the poison in the reacting system. The revivification of poisoned catalysts is briefly discussed.

J. H. PERRY

The chemical equilibrium between lead sulfide and its roasting products. III.

RUDOLPH SCHENCK. *Z. anorg. allgem. Chem.* 148, 351-68(1925); cf. *C. A.* 19, 1981—The data given in the previous papers are revised theoretically and a complete system for both cases: the roasting with an insufficient amt. of O (PbS present) and with excess O (PbS absent) is established.

JOHN T. STERN

Studies of equilibrium in systems of the type $Al_2(SO_4)_3-M''SO_4-H_2O$. II. Aluminum sulfate-nickel sulfate-water at 30°. R. M. CAVEN AND T. C. MITCHELL. *J. Chem. Soc.* 127, 2549-50(1925); cf. *C. A.* 19, 3440.—There is no evidence of double salt formation between $Al_2(SO_4)_3$ and $NiSO_4$ in soln. at 30°. To avoid the tendency for false end points in the *estn.* of *Ni* in the presence of *Al*, the $NaAl_2O_4$ soln. (cf. Sutton, *Vol. Analysis* (1924), p. 278) was added to an aliquot portion until the ppt. first formed began to redissolve. The ppt. was then completely dissolved by an excess of ammonia, and the soln. dild. to working vol. Dil. H_2SO_4 was added almost to neutralization and the titration was then carried out in the usual manner.

D. S. VILLARS

The lattice energy of the ammoniates. WILHELM BILTZ AND H. G. GRIMM. *Z. anorg. allgem. Chem.* 145, 63-87(1925).—The lattice energy of the ammoniates is equal to the lattice energy of the NH_3 -free salts plus the heats of formation of the ammoniates. On this basis, the lattice energy of a no. of ammoniates has been calcd. With equal nos. of added NH_3 's, the lattice energy decreases with increasing radius of the cations or of the anions. The lattice energy of the ammoniates of salts whose cations have 18 or 20 external electrons is higher than that of the corresponding ammoniates of the same period which have 8 external electrons. The lattice energy of different ammoniates of the same salt increases with the no. of NH_3 's attached, the increase per NH_3 diminishing with the no. of NH_3 's already attached. The increase in the lattice energy for the same no. of NH_3 's in different salts of cations having the same no. of external electrons is greater the higher the charge and the smaller the radius of the cation. The differences between the lattice energy of ammoniates with the same no. of NH_3 's and the same cation but 2 different halides decreases with increasing NH_3 if the cation has 8 external electrons but increases if it has 18 or 20. The stability of the corresponding ammoniates with different halogen ions depends on the lattice energy of the ammonia-free salt, whether the heat of formation from the chloride to the iodide increases or decreases. With the aid of the lattice theory of Born and Landé, the work of adding or removing NH_3 may be calcd. With $KI \cdot 6NH_3$, the work is about 14 Cal. per NH_3 . With the hexamines of the alk. earth metals, it is about twice that. For $CaF_2 \cdot 6NH_3$, a negative result is obtained which is in agreement with the fact that this compd. cannot be made by the direct combination of NH_3 gas and cryst. CaF_2 .

A. W. K.

The chemistry of complex natural substances. HANS PRINGSHEIM. *Naturwissenschaften* 13, 1084-90(1925).—A review with bibliography. Abundant evidence is given for the theory that naturally occurring substances, starch, cellulose and proteins are built up by secondary valence polymerization from (often labile) simple substances.

B. J. C. VAN DER HOEVEN

Oxidation potentials and equilibria in the system: chlorine, iodine, hydrochloric acid, water. G. S. FORBES, S. W. GLASS AND R. M. FUOSS. *J. Am. Chem. Soc.* 47, 2892-903(1925).—Oxidation potentials at 25° for Cl_2 , for $ICl_3 + Cl_2$, for ICl_3 , and for ICl , have been measured in HCl 4, 5, and 6 *N* against H electrodes in the corresponding acids throughout a wide range of concn. The results are expressed by linear equation involving the normal (molal) potential. The following consts. were detd. and are

independent of the acid concn. within the limit of error: $(\text{ICl})(\text{Cl}_2) = 7.2 \times 10^{-14}$ (ICl_3); $(\text{I}_2)(\text{Cl}_2) = 7.8 \times 10^{-16}(\text{ICl})^2$; $(\text{I}_2)(\text{ICl}_3) = 1.1 \times 10^{-11}(\text{ICl})^3$. The systems can be titrated electrometrically with great accuracy. All relations could be explained on the basis $\text{Cl}_2 + 2\ominus = 2\text{Cl}^-$ and scarcely any on the basis $\text{ICl} = \text{I}^+ + \text{Cl}^-$. There does not appear to be any evidence in support of the ion I^+ .

A. W. KENNEY

The condensed ternary system phenol-water-salicylic acid. C. R. BAILEY. *J. Chem. Soc.* 127, 1951-65(1925).—The ternary system has been studied by both analytical and synthetic methods, the latter being of particular value in studying metastable regions. PhOH was estd. by the bromide-bromate method. Salicylic acid, even in the presence of PhOH, was titrated with $\text{Ba}(\text{OH})_2$ using *p*-nitrophenol. H_2O was detd. by difference. In the binary system PhOH- H_2O , the crit. soln. temp. is 65.3° , corresponding to 36.5% PhOH; and the eutectic is at 1.2° with 6.5% PhOH. The ternary diagrams, as detd. by points of crit. opalescence, differ somewhat from those detd. by analysis or by the points of sudden thickening, the last two methods giving concordant results. No compds. or mixed crystals were observed. The binary system H_2O -salicylic acid gives 2 liquid layers in the metastable region. The system PhOH- H_2O has 2 liquid layers in the stable region and the phenomenon of "melting under the liquid" occurs at easily accessible temps. and in accordance with Schreinemaker's generalization. Salicylic acid has very slight soly in H_2O but a much higher soly. in PhOH and still higher in mixts. of PhOH and H_2O . Detailed data are given and different ternary and binary systems and isotherms are illustrated by diagrams.

A. W. KENNEY

The system water and the nitrates of potassium and ammonium at 25° . KINJI ANDO. *Mem. Coll. Sci. Kyoto Imp. Univ.* 8, 284-6(1925). (In English), cf. Rutgers, *Z. physik. Chem.* 4, 622.—Roughly calcd. proportions of KNO_3 and NH_4NO_3 were dissolved in H_2O by warming and the soln. was brought to equil. at 25° . The liquid and the solid phases were sep'd and analyzed. The transition points (1) for the 2 series of solid solns. were for solid KNO_3 satd. with NH_4NO_3 at 13.5% NH_4NO_3 and for solid NH_4NO_3 satd. with KNO_3 at 65% NH_4NO_3 ; (2) for the liquid phase satd. with both salts at 79.41% NH_4NO_3 . The H_2O content in the liquid phase decreased to 2.18% with the addn. of NH_4NO_3 and then became const. All values are expressed as mol. fractions %.

H. M. McLAUGHLIN

The equilibrium in the system consisting of potassium sulfate, potassium nitrate and water at 25° . RYOHEI INOUE. *Mem. Coll. Sci. Kyoto Imp. Univ.* 8, 287-90 (1925). (In English).—The method was the same as used by Ando (cf. preceding abstr.). The solid phases were K_2SO_4 and KNO_3 only (cf. Massink, *C. A.* 11, 3181). Transition points occurred for the liquid phase at 14.89% K_2SO_4 with 26.49% H_2O and for the solid phases at 87.82% K_2SO_4 and 1.74% K_2SO_4 . All values are expressed as mol. fraction %.

H. M. McLAUGHLIN

The system silver sulfate-aluminium sulfate-water at 30° . R. M. CAVEN and T. C. MITCHELL. *J. Chem. Soc.* 127, 2550-1(1925).—It was decided that Ag_2SO_4 and $\text{Al}_2(\text{SO}_4)_3$ do not form a cryst. alum from mixts. at 30° . This is in disagreement with Kern (cf. *Chem. News* 31, 209(1875)) and Church and Northcote (cf. *ibid.* 9, 155 (1864)).

D. S. VILLARS

A method for the investigation of binary systems. I. The "thaw"-melting-point diagram. HEINRICH RHEINBOLDT, KURT HENNIG and MARINETTE KIRCHHEISEN. *J. prakt. Chem.* 111, 242-72(1925).—In the study of binary systems in which (I) components do not form compds. with each other, (II) components unite to a homogeneous melting compd., (III) components form a non-homogeneous melting compd. the authors suggest that the temps. at which melting begins, "Auftaupunkt," be plotted as well as the usual m. p. The "Auftau" curve coincides with the m. p. curve at the m. p. of the pure components and the eutectics. In this way it indicates maxima in the m. p. curve which are sometimes indistinct because of the extreme flatness of the curve. The values obtained agree with those of other investigators. The diagrams of the following systems are given and discussed: (I) naphthalene-*p*-nitrophenol; α -naphthol- β -naphthylamine; pyrocatechol-naphthalene; (II) β -naphthylamine-1,3,5-trinitrobenzene; β -naphthylamine-nitrosodimethylaniline; naphthalene-picric acid; phenol-picric acid; urea-phenol; benzamide-nitrosodimethylaniline; *m*-hydroxybenzaldehyde-picric acid; antipyrine-hydroquinone; (III) acetamide-salicylic acid; anthracene-picric acid; *p*-dinitrobenzene- α -naphthylamine; *p*-dinitrobenzene- β -naphthylamine.

J. R. SCHIERZ

The supposed isomorphism of compounds of uranyl with those of the isomorphogenic metals of the magnesium group. G. CAROBBI. *Gazz. Chim. Ital.* 55, 406-10 (1925).—See *C. A.* 18, 2655.

E. J. WITZEMANN

The study of the relations of isomorphism between compounds of beryllium and those of magnesium. F. ZAMBONINI AND G. CAROBBI. *Gazz. chim. ital.* **55**, 330-5 (1925); *Atti accad. Lincei* [5] **33**, II, 218-22 (1924).—The isomorphic relations between Be and Mg in chem. preps. and in minerals are fully reviewed. These data show that Be can substitute for Mg isomorphically in some minerals at least but the miscibility of Be compds. with the corresponding Mg compds. in the solid state is quite limited. Z. and C. have investigated this subject further with double nitrates of the Ce group of the type $Mg_3X_2'''(NO_3)_{12} \cdot 24H_2O$. Attempts to obtain a double nitrate between Be and La failed. It was then attempted to stabilize the compd. $Be_3La_2(NO_3)_{12} \cdot 24H_2O$ in mixed crystals with $Mg_3La_2(NO_3)_{12} \cdot 24H_2O$. To a soln. contg. 5.25 g. $La(NO_3)_3 \cdot 6H_2O$ and 4.2 g. $Be(NO_3)_2 \cdot 4H_2O$ a large excess of the Mg-La salt was added. The 1st fractions were nearly pure $Mg_3La_2(NO_3)_{12} \cdot 24H_2O$ (nearly free from Be). The final fractions contained 5.4-7.6% $Be_3La_2(NO_3)_{12} \cdot 24H_2O$. To the mother liquors 2 g. each of the Be and La nitrates were added. The solns. were concd., cooled rapidly and seeded with crystals of the previous fraction. They gave mixed crystals contg. 18.9% of the Be-La salt; this could not be increased by successive attempts. Z. (C. A. **19**, 1529) has recently discussed the relation of the isomorphism to at. structure as proposed by Bohr. The structure of Be and Mg is quite different.

	1 ₁	2 ₁	2 ₂	3 ₁
Be	2	2		
Mg	2	4	4	2

The marked difference is sufficient to explain the rather scarce isomorphic relations.

E. J. WITZEMANN

Investigations on the acid nature of some derivatives of sulfur, selenium and tellurium. D. D. KARVE. *Quart. J. Indian Chem. Soc.* **2**, 128-41 (1925); cf. C. A. **19**, 3203.—The acid nature of a compd., as regards its existence as a "true" acid or a "pseudo-acid," might be investigated by considering (1) the effect of the compd. on an indicator (dimethylaminoazobenzene), (2) the absorption spectra of solns. of the compd., (3) the effect of the compd. on the rate of inversion of cane sugar, and (4) the effect of the compd. on the velocity of decomn. of diazoacetic ester. The use of some or all of these methods led to the following conclusions: (1) In the pure state or in aq. soln., $MeSO_3H$ and $EtSO_3H$ exist as true acids ($ROSO_3H$); in dil. $EtOH$ solns. and even in concd. H_2O solns. the acids are present as pseudo-acids ($ROSO_2OH$). (2) H_2SeO_3 in aq. soln. is present partly as the true monobasic acid ($OHSeO_2H$) but chiefly as the pseudo-acid ($SeO(OH)_2$); in dil. $EtOH$ soln. it is present entirely as pseudo-acid. (3) H_2SeO_4 , like H_2SO_4 , exists in water either as true acid or as its oxonium salt; the addn. of $MeOH$ causes partial formation of pseudo-acid. (4) $C_6H_5SO_2H$ and $C_6H_5SO_3H$ are present as true acids in aq. solns. and as pseudo-acids in the pure state or in org. solvents. (5) $C_2H_5SeO_2H$ exists as pseudo-acid even in aq. soln. (6) H_2TeO_3 is a pseudo-acid of the formula $OTe(OH)_2$. (7) Ordinary telluric acid ($H_2TeO_4 + 2H_2O$) (I) is actually $Te(OH)_6$; allotelluric acid (prepd. by heating I in a sealed tube to 140°) is a true acid of formula " $(OH)_3TeO_2 \cdot H_2O$ "; anhyd. telluric acid should be represented as $O_2Te(OH)_2$.

DONALD W. MACARDLE

The thermal decomposition of some chloro salts of the platinum metals. I. Contribution to the study of monovariant systems. G. GIRE. *Ann. chim.* **4**, 183-221 (1925).—The dissociation pressures of several metallic chloroplatinates have been studied. $\frac{1}{2} K_2PtCl_6 \rightleftharpoons \frac{1}{2} Pt + KCl + Cl_2$ gives the following data: 607° , 4.4 mm.; 708° , 39.2, 801° , 245; 854° , 681; 921° , 1750 mm. For $\frac{1}{2} Na_2PtCl_6 \rightleftharpoons \frac{1}{2} Pt + NaCl + Cl_2$: 503°, 6 mm.; 601°, 64.4; 651°, 252; 720°, 848; 758°, 1450 mm. For $\frac{1}{2} BaPtCl_6 \rightleftharpoons \frac{1}{2} Pt + \frac{1}{2} BaCl_2 + Cl_2$: 428°, 4.6 mm.; 556°, 80.3; 607°, 210; 655°, 531; 721°, 1600 mm. For $\frac{1}{2} K_2IrCl_6 = \frac{1}{2} Ir + KCl + Cl_2$: 574°, 9.2 mm.; 651°, 30.7; 706°, 83.0; 751°, 189; 808°, 541; 844°, 933. For $2K_2IrCl_6 + 2KCl \rightleftharpoons 2IrCl_6K_3 + Cl_2$: 480°, 3.8 mm.; 552°, 24.3; 603°, 67.9; 705°, 437; 795°, 1610 mm. For $\frac{2}{3} Na_3RhCl_6 \rightleftharpoons \frac{2}{3} Rh + 2NaCl + Cl_2$: 609°, 14.0 mm.; 712°, 73.3; 751°, 120; 800°, 274; 825°, 460 mm. Additional data for each salt are given in the original. Each of the above reactions is reversible. At about 700° , K_2PtCl_6 goes to K_2PtCl_4 as: $K_2PtCl_6 \rightarrow Pt + 2KCl + Cl_2 \rightarrow \frac{1}{2} Pt + KCl + \frac{1}{2} K_2PtCl_6$. With an excess of KCl, the formation of chloro-iridate is limited by the reversible reaction: $2K_2IrCl_6 + 2KCl \rightleftharpoons 2K_3IrCl_6 + Cl_2$. At the m. p. of KCl, the tangents to the dissocn. curves of K_2PtCl_6 and K_2IrCl_6 undergo a sudden change which gives the mol. heat of fusion of KCl of about 5 Cal. From the break in the curve for Na_3RhCl_6 , the heat of fusion of $NaCl$ is calcd. to be 5.67 Cal. II. Calorimetric researches on the chloro salts studied. *Ibid* 370-409.—The following

heats of soln. and reaction have been measured (kg. Cals.): K_2PtCl_6 soln. + Aq. = -12.15 ; Na_2PtCl_6 soln. + Aq. = $+7.10$; BaPtCl_6 soln. + Aq. = $+9.05$; $\text{BaPtCl}_6 \cdot 6\text{H}_2\text{O}$ + Aq. = -1.06 ; Na_3RhCl_6 soln. + Aq. = $+7.70$; $\text{Na}_3\text{RhCl}_6 \cdot 12\text{H}_2\text{O}$ + Aq. = -20.56 ; K_2IrCl_6 soln. + Aq. = -13.12 ; K_2IrCl_6 soln. + Aq. = -7.90 ; K_2PtCl_6 soln. + Co = $+100.90$; Na_2PtCl_6 soln. + Co = $+99.10$; BaPtCl_6 soln. + Co = $+100.90$; Na_3RhCl_6 soln. + Aq. = $+56.50$. The Thomsen-Pigeon hypothesis that "The heats of formation of all the dissolved chloroplatinates, starting from the dissolved chlorides, is the same," has been verified, but, for the reaction $\text{Pt} + \text{MCl}_2 + 2\text{Cl}_2 = \text{MPtCl}_6 + Q$, Q has been found equal to 89 Cals., a new value. It has been shown that the reduction of K_2IrCl_6 by Co and by CrCl_2 takes place in 2 steps: $2\text{K}_2\text{IrCl}_6 + 2\text{KCl} = 2\text{K}_3\text{IrCl}_6 + \text{Cl}_2 - Q$ and $2\text{K}_3\text{IrCl}_6 = 2\text{Ir} + 6\text{KCl} + 3\text{Cl}_2 - Q'$, the second step being much the slower. The soly. of K_2IrCl_6 in H_2O was detd. to be at 0° , 0.66 g. and at 20° , 1.12 g. per 100 g. H_2O . The existence of the hydrate $\text{Na}_3\text{RhCl}_6 \cdot 12\text{H}_2\text{O}$ has been proven. From the heats of dissociation as a function of the temp. the ratio of the heat of reaction to the abs. temp. is 0.0325. For ammoniacal chlorides, this ratio is 0.032; for hydrides, oxides, carbonates and chlorides, it varies from 0.028 to 0.034. AuCl_3 gives a ratio of 0.0326. J. H. PERRY

Thermochemistry of beryllium. C. MATIGNON AND G. MARCHAL. *Compt. rend* **181**, 859-61 (1925).—The following heats of reaction have been measured: BeO (prepd. at 1000°) + 30% HF, $Q = 23.3$ kg. cal. at 17° ; $\text{Be}(\text{OH})_2 + 2\text{HCl}$ (aq.), $Q = 13.65$ kg. cal.; $\text{BeSO}_4 \cdot 4\text{H}_2\text{O}$ + aq., $Q = 1.5$; $\text{BeSO}_4 \cdot 2\text{H}_2\text{O}$ + aq., $Q = 8.0$; $\text{BeSO}_4 + \text{NaOH}$ (111.8 g. per l.), $Q = 34.5$; $\text{BeSO}_4 \cdot 2\text{H}_2\text{O} + \text{NaOH}$ (111.8 g. per l.), $Q = 17.5$; $\text{Be} \cdot \text{SO}_4$ aq. + BaCl_2 , $Q = 6.95$; BeCl_2 + aq., $Q = 51.1$ kg. cal. F. R. BIGNOWSKY

The temperature of the vapor evolved from a solution. E. REISSMANN. *Z. anorg. Chem.* **38**, 1040-4 (1925); cf. *C. A.* **19**, 917. In order to eliminate different possible sources of error the app. previously used was further improved. The results reported in the first paper agree with those of the 2nd communication. In addn. indirect expts. were carried out based on the following idea: Vapor which has the temp. of the boiling solvent is introduced into a soln. boiling at a higher temp.; then there should be an equil. according to Faraday, while a condensation of the vapor should take place according to Gay-Lussac, accompanied by a lowering of the temp. of the boiling soln. On the other hand if the temp. of the vapor is higher than that of the solvent, but lower than that of the soln., part of the soln. should evaporate and the b. p. should rise according to Faraday, while this should not take place according to Gay-Lussac; the temp. of the soln. will rise according to the latter only if the temp. of the vapor is higher than that of the solvent. The expts. prove the correctness of Gay-Lussac's opinion. Thus the vapor evolved from a soln. has the temp. of the soln. and not that of the solvent, as demanded by Faraday. EMIL KLARMANN

The latent heat of vaporization of liquid oxygen-nitrogen mixtures. L. I. DANA. *Proc. Am. Acad. Arts Sci.* **60**, 241-67 (1925).—This research deals with the detn. of the latent heat of vaporization at atm. pressure of liquid O_2 , N_2 and of mixts. of the 2 in all proportions. A new calorimeter is described which is designed for the detn. of the latent heats at low temps. of pure liquids and their binary mixts. The calorimetric method adopted is the continuous-flow method at const. pressure. A latent heat is defined and measured which involves the change in heat content from the liquid state to the vapor state vertically above it on the vapor line in the temp.-compn. diagram. The latent heats of vaporization of liquid O_2 and of liquid N_2 are 50.01 cal. (15°) per g. and 47.74 cal. per g., resp. The values of the latent heats of the mixts. read from a smooth curve drawn through the exptl. points, are tabulated and the accuracy is estd. to be within 0.2%, and in most cases within 0.1%. W. H. BOYNTON

The thermal dissociation of sodium carbide. E. W. GUERNSEY AND M. S. SHERRMAN. *J. Am. Chem. Soc.* **48**, 141-6 (1926).—An app. and techniq. for the prepn. of Na carbide from C_2H_2 and molten metallic Na are described. The dissocn. pressure of Na vapor from solid carbide is represented approx. by the equation, $\log p = 9059 - 6609/T$. The dissocn. pressure becomes 1 atm. at about 800° . It follows that any Na carbide which is formed as a step in the fixation of N as cyanide can exist only in the gas phase, since considerably higher temps. are required for the fixation. At 700° , Na carbide in the gas phase is largely dissocd. the partial pressure of gaseous Na carbide over solid Na carbide being about 0.6 mm. Hg as compared with 191 mm. dissocn. pressure of Na. F. R. B.

The chemistry of calcium cyanamide. I. The heat content of calcium cyanamide. H. H. FRANCK AND FRITZ HOCHWALD. *Z. Elektrochem.* **31**, 581-90 (1925).—The heat of combustion of almost pure CaCN_2 is 163.1 ± 0.4 kg. cal. The directly measured heat of nitrogenation of CaC_2 is 72.0 ± 2.0 kg. cal. The heat of combustion of MgCN_2

is 179.5 kg. cal. The heat of combustion of Mg is 146.1 kg. cal. These values are all for const.-vol. processes. The calcd. heats of formation for CaCN_2 and MgCN_2 are 84.0 and 61.0 kg. cal., resp.

Absolute critical temperatures. MAURICE PRUD'HOMME. *Bull. soc. chim.* **37**, 1330-40 (1925).—(1) *Relationships in groups of 2, 3 and 4 compds.* P. shows by many examples, that the difference between the abs. crit. temps. (T_c) of 2 compds. of a group, made up of binary or tertiary compds. of any 3 elements, is equal to the difference between some other 2. Thus, $\text{CS}_2 = 550$, $\text{CO}_2 = 304$, $\text{CO} = 132$, $\text{COS} = 378$; $\text{CS}_2 - \text{CO}_2 = 246 = \text{COS} - \text{CO}$, or $\text{CS}_2 + \text{CO} = \text{COS} + \text{CO}_2 = 682$. Similar associations are possible with derivs. of N, cyanogen, nitriles, ethers, etc. T_c for $\text{H}_2\text{O} = 647$ is twice that for $\text{HCl} = 324$. (2) *Addns. of T_c .*—P. states that the T_c for an inorg. compd. is equal to the sum of the simple multiples or fractions of the T_c of the constituent elements. T_c for metallic elements, when present, is ignored except in the case of Si, when a const. is required. Thus $\text{SO}_3 = 606 - \frac{3}{2}\text{O} + \frac{1}{3}\text{S} = 600$; $\text{PH}_3 = 324 - \frac{1}{3}\text{P} + \text{H} = 322$; $\text{TiCl}_4 = 631 - \frac{3}{2}\text{Cl} = 628$; $\text{SiCl}_4 = 501 - \text{Cl} + 82 = 501$. The no. of ats and the no. of valences in the mol. appear to be the guide in such calcs. but the general rule is not clear. P. illustrates the idea structurally as follows: $\text{O}=\text{S}=\text{O}$, $\frac{1}{2}\text{O}-\text{S}/3-\frac{1}{2}\text{O}$. (3) *Substances contg. 1 C atom.*—The T_c of C as with

the metals is ignored although it plays a part in compds. with more than 1 C atom. Thus, $\text{CS}_2 = 550 - \frac{1}{2}\text{S} = 550$; $\text{CH}_2\text{Cl} = 518 - \text{Cl} + 3\text{H} = 515$. (4) *Org. compds. of more than 1 C atom* may be split into groups contg. 1 or 2 C atoms and possessing 1 or 2 free valences. The sum of the T_c for these groups gives the T_c of the compd. in question. The principal groups are CH_3 , CH_2 , CH_3CH_2 , CH_2OH (alcs.), HCO_2 (esters), COOH (acids), etc. Thus, $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH} \cdot \text{CH}_2 = 474 = 185 + 52 + 52 + 185$; $\text{HCO}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3 = 551 = 323 + 22 + 22 + 185$. Hydrocarbons having the same no. of valences have the same T_c and in general T_c is an exponential function of the no. of valences. $T_c = \text{CV}^n$. For hydrocarbons, $n = 0.489$, $\log C = 2.0391$ and for alcs. $n = 0.1462$, $\log C = 2.5366$. Detd. values for T_c and for alcs., hydrocarbons, org. salts, acids, nitriles, etc., agree well with values calcd. either by addn. of group values or by use of the valence equation. Thus, for Pr alc. 537, 538 and 540, resp., butane 423, 422 and 424, Me formate 485, 475 and 474. The values given for some of the common groups are $\text{CH}_3 = 152$, $\text{CH}_2\text{CH}_2 = 185$, $\text{CHCH}_2 = 185$, $\text{CH}_2\text{CH}_2 = 52$, CH_2CH_2 (alcs., salts and fatty acids) = 22, $\text{OH} = 331$, $\text{HCO}_2 = 323$, $\text{CO}_2 = 192$, $\text{H} = 31$, $\text{N} = 127$.

A derivation of Saha's equation for temperature ionization. W. F. G. SWANN. *J. Franklin Inst.* **200**, 591-4 (1925).—Saha's equation is derived in a simple manner by equating the variation of Boltzmann's expression for the entropy of monat. gases. to $\delta S = Q_p/T$, where Q_p is the heat necessary for ionization of δn ats. B. J. C. v. H.

Remarks on the statistical definition of entropy of an ideal gas. E. SCHRÖDINGER. *Sitzb. preuss. Akad. Wissenschaften* **1925**, 434-41.—There are 4 definitions of entropy which are often confused: (1) $S = k \ln W_{\text{max}}$, where W_{max} is the max. no. of permutations at const. energy which can define a given state. $S = k \ln \Sigma W$, where ΣW is the sum of the no. of permutations for all possible states consistent with const. energy. (3) This definition is formally the same as (2) but is derived from (1) by a faulty application of Stirling's formula (4) $S = k \ln T$, where T is the total no. of all possible arrangements consistent with the total energy. All of these formulas give results consistent with the Nernst's law. S. prefers the fourth.

F. R. BICHOWSKY

The statistical definition of entropy. MAX PLANCK. *Sitzb. preuss. Akad. Wissenschaften* **1925**, 442-51.—The entropy is defined as proportional to the log of the total no. of stationary states consistent with the total energy E . This definition leads to a simple proof of the Planck law for a system of oscillators.

F. R. B.

A mass-action equation for compressed gases with application to the Haber equilibrium data. L. J. GILLESPIE. *J. Am. Chem. Soc.* **48**, 28-34 (1926).—The rule of Lewis and Randall that the fugacity of any component of a mixed gas is proportional

to its mol. fraction is tested with the best data for the equation of state of H_2 , N_2 and NH_3 and the equil. const. for the Haber reaction. Close agreement is found up to 100 atms.; above that, systematic variations occur due presumably to faulty equations of state. F. R. B.

Polonium and bismuth as amphoteric elements. FRITZ PANETH and BENJAMIN HEINZ. *Z. Elektrochem.* 31, 572-6(1925).—Po, like Tc, may be electrolytically dissolved and deposited both at anode and cathode, in KOH soln. Results in acid soln. were less conclusive. The cathode potential is between that of Au and Ag. Thorium C was used as a radioactive indicator for Bi; it gives similar results in alk. soln. With both elements, the ratio of anodic to cathodic dissolution decreases with increasing KOH concn., approaching 1. B. H. CARROLL.

Solubility measurements on ampholytes. H. EULER and K. RUDBERG. *Arkiv. Kemi Mineral. Geol.* 9, No. 18, 1-6(1924); *Z. anorg. allgem. Chem.* 145, 58-62(1925).—The sp. change in soly. AS of nonelectrolytes by neutral salts is expressed by the formula $AS = -(1/n)[(l_w - l_s)/l_w]100$ where l_w is the soly. of the nonelectrolyte in water, l_s its soly. in salt soln. and n the concn. of the salt. The increase in soly. of amino acids is dependent on the distance between the 2 elec. charges in the mol; hence glycylglycine should have a greater AS than tyrosine or leucine. Expts. confirm this theory. In accordance with the Bjerrum theory of ampholytes the soly. of methyl orange at definite pH is greater in a glyccoll soln. than in water. W. F. GOEBEL.

Electrical conductivity of phosphorus pentachloride. G. W. F. HOLROYD, HARRY CHADWICK and J. E. H. MITCHELL. *J. Chem. Soc.* 127, 2492-3(1925); cf. *C. A.* 18, 28.—This preliminary communication, for priority purposes, announces the intention of studying PCl_5 ions and soln. of PCl_5 in C_6H_6 . A method of prepg. pure PCl_5 and PCl_3 is given. R. E. GIBSON.

Electrical resistance of tungsten wire. JUN TSUKAMOTO. *Nagaoka Anniv. Vol.* 1925, 409-12; *Japan. J. Physics* 4, 22A.—The variation in elec. resistance of W was detd. when the rectangular sintered rods, contg. 1% of thoria, were swaged and drawn down to thin wires. The av. sp. resistance of the sintered rod, about 0.47 by 0.47 cm.² in section, is 6.1 microöhm at 20°. It decreases rapidly with the swaging operation and reaches a min. value of 5.7 microöhm at 4.5 mm. diam. By further swaging it increases gradually and attains a value of 5.9 at 0.75 mm. As this is drawn down to 0.35 mm. the sp. resistance increases steadily, attaining 6.0 microöhm at 0.35 mm., below which the rate of increase becomes more rapid and reaches 7.1 at 0.015 mm. The sp. resistance of sintered rods depends upon the fineness of W powder from which they have been made and also upon the time of heating. For wires it depends on the drawing temp. C. J. WEST.

On the work of Bernhard Neumann and Helmut Richter: "The potentials of fluorine, determined by measurements of the decomposition potentials of molten fluorides." OTTO RUFF and WERNER BUSCH. *Z. Elektrochem.* 31, 614-5(1925).—Cf. Neumann and Richter (*C. A.* 20, 141). B. H. CARROLL.

Investigations of electrolyte filaments. I. The behavior of streaming electrolyte filaments traversed by an electric current and their deviation by a magnetic field. E. MANEGOLD. *Z. anorg. allgem. Chem.* 145, 181-92(1925).—The effect of a magnetic field on a soln. contg. electrolytes has been utilized in analytical chemistry but little investigation made of this phenomena. An app. is described in which a thin stream of dyed salt soln. passes through a chamber contg. pure H_2O . Electrodes are inserted so that a current may be passed through this filament, and the filament may also be subjected to the action of a magnetic field. It was found that without a magnetic field, the filament could be thickened or broken by changing the intensity of the current flowing through it, and it was sharply deviated from its rectilinear position by the action of the magnetic field, the direction of deviation following the same law as for a metallic conductor. The preliminary expts. described are to be followed by a more comprehensive study. A. W. KENNEY.

Ionic mobilities in solid cuprous sulfide and silver sulfide. H. BRAUNE and O. KAHN. *Z. Elektrochem.* 31, 576-81(1925).—Continuation of the expts described in *C. A.* 19, 3196. The diffusion const. of the Cu ion in Ag_2S with 5% Cu_2S is expressed by $D = 40.3 e^{-(1490/T)}$. Diffusion of Se in Ag_2S contg. Ag_2Se was measured by a colorimetric detn. of Se. $D = 59.3 e^{-(10120/T)}$. These results are in agreement with the relative mobilities of cation and anion in solid salts as detd. by elec. cond. methods. B. H. CARROLL.

Dielectric constants of electrolytic solutions. H. ULICH. *Z. Elektrochem.* 31, 413-7(1925).—A review of the work of Walden and U. (*C. A.* 19, 1809, 2440, 3058). Curves are given for the dependence of the dielec. const. ϵ on the concn. of added salt,

and possible interpretations in the light of the theories of Debye and Hertz are discussed.

H. R. MOORE

The electrolytic oxidation of the quadrivalent molybdenum octacyanides. OSCAR COLLENBERG AND BJÖRN ANDERSEN. *Z. Elektrochem.* **31**, 558-65(1925).—The electrolytic oxidation of the Mo^{IV} cyanide of the type $\text{M}_4\text{Mo}(\text{CN})_8$ to Mo^{V} cyanide of the type $\text{M}_3\text{Mo}(\text{CN})_8$ has been accomplished by C. and A. and is considered a method to obtain a c. p. material for the study of the photochem. actions on this very light-sensitive compd. In the general procedure for this oxidation with KMnO_4 there is always a possibility of contaminating the material with a small amt. of Mn^{++} , which is known to act as a strong photochem. catalyst and thus may interfere with the true reactions. Expts. were carried out in acid, alk. and neutral solns. with anodes of Pt, Au, Fe and Ni, and a Pt cathode. The oxidation could be conducted without decompn. of the complex Mo^{V} cyanide in either case with anodes of Pt or Au under proper conditions. Fe and Ni were unsuitable. As anolyte was used a 0.108 *M* $\text{K}_4\text{Mo}(\text{CN})_8$ soln. On electrolysis in a 0.1 *N* H_2SO_4 soln., with a 0.1 *N* K_2SO_4 soln. as catholyte, the oxidation is quant. In the alk. oxidation with an alk., 0.5 *N*, only 92% could be oxidized in the best case, because of self reduction of the $\text{Mo}^{\text{V}}(\text{CN})_8$ ion at the end of the reaction. Comparatively high alk., as well as a sufficiently high temp. was found necessary to avoid decompn. The electrolysis in a neutral soln. could not be completed without addn. of other salts, because of decompn. of the complex cyanide ion. With the addn. of K_2SO_4 to 0.1-0.2 *N* this could be avoided and quant. results obtained. D. MIESEY

Various physical properties of rubidium and cesium and the resistance of potassium under pressure. P. W. BRIDGMAN. *Proc. Am. Acad. Arts Sci.* **60**, 385-421(1925).—New data for Rb and Cs are given as follows: cubic compressibility up to 15,000 kg./cm.², elec. resistance of the solid and liquid phases as a function of pressure and temp. between 0° and 100°, up to 12,000 kg./cm.², both for bare wires and for the metals enclosed in glass capillaries; and the complete melting data (variation of the *m. p.* with temp. and pressure and the change in vol. whence the latent heat is calcd.) from 0° to 100° and up to 12,000 kg./cm.². Extrapolating from the temp.-pressure curves for the *m. p.* B. gives 38.7° and 29.7° as the *m. ps.* at atm. pressure of pure Rb and Cs, resp. The initial compressibilities of Rb and Cs are given as 0.0452 and 0.0470. In the case of Cs the elec. resistance-pressure curve passes through a *minimum* around 4000 kg./cm.². This is shown to be an inherent property of the element and not to be due to its crystal structure. There are indications that the curve for Rb behaves similarly at very high pressures. The bearing of this phenomenon on the *theories of metallic conduction* is discussed. The elec. resistance of K and its temp. coeff. under pressure have been redetd. on bare wires instead of glass capillaries, which were shown to exert a constraining action on the metal. The temp. coeff. of the elec. resistance of K does not decrease rapidly at high pressures, as was previously stated. In discussion the above properties of all the alkali metals are compared and the "electronic volume" (at. vol./at. no.) is plotted against pressure. K. is anomalous in "electronic vol." (the anomaly disappears at 10,000 kg./cm.²), compressibility and melting data. Except in the case of Li, the fractional changes in vol. on melting and the latent heats of all the alkali metals are nearly the same, but the pressure-vol.-temp. relations of a compressible alkali element at high pressures are not similar to those of a less compressible one at lower pressures as has been supposed. *Methods of purifying Rb and Cs* are given.

R. E. GIBSON

Effect of tension on the transverse and longitudinal resistance of metals. P. W. BRIDGMAN. *Proc. Am. Acad. Arts Sci.* **60**, 423-49(1925).—A new exptl. method is given for measuring the change of resistance in a metal when the direction of the current is at right angles to the stress (transverse coeff.). The method gives the geometric mean of the transverse and longitudinal coeffs. whence, with the help of a direct detn. of the latter, the former can be found. The math. theory of the method is given in detail. Of the 8 metals examd. Ni is abnormal. The values for the softer metals, Al, Au, Ag, Cu, are doubtful. Exptl. details are given and the results are discussed with their bearing on the electron free path theories of metallic conduction. Results are given for Al, Au, Ag, Cu, Pd, Pt and Fe.

R. E. GIBSON

Points of magnetic transformation in the system sesquioxide of iron-magnesia. H. FORESTIER AND G. CHAUDRON. *Compt. rend.* **181**, 509-11(1925).—A study of the system $\text{Fe}_2\text{O}_3\text{-MgO}$ at various temps. by dilatometry and also by magnetic susceptibility. The results show the existence of $\text{Fe}_2\text{O}_3\text{.MgO}$.

S. K. ALLISON

The configuration of the ammonium ion. WM. H. MILLS AND E. H. WARREN. *J. Chem. Soc.* **127**, 2507-14(1925).—A crucial test between the tetrahedral and pyramidal configurations of the NH_4 ion is provided by the spirocyclic ammonium radicals, which

should be symmetrical on the latter and unsymmetrical on the former hypothesis. 4-Phenyl-4'-carbethoxybispiperidinium-1,1'-spiran bromide was prepared, and by fractionation of its d- α -bromocamphor- π -sulfonate, was successfully sep'd. into optical isomers with rotation $[M]_{5461} = 50.5-8^\circ$ and $[M]_{5780} = 44.9^\circ$. Prepn. of the spirocyclic comp'd. is described in detail.

Molecular asymmetry and optical activity. E. DARMOIS. *J. phys. radium* **6**, 232-40(1925).—A lecture with bibliography. The theories of optical rotatory power are briefly reviewed, in particular the one of Mallemann (*C. A.* **18**, 3527). Evidence is given for the necessity of assuming chem. combinations and elec. effects in solns. for the explanation of the optical rotation value.

Optical anisotropy of selectively absorbing substances; mechanical production of anisotropy. HANS ZOCHER. *Naturwissenschaften* **13**, 1015-21(1925).—A review is given of expts. with streaming liquids contg. nonspherical dye particles and with directionally polished surfaces of either org. dye layers or metals and metal oxides. Generally these systems show dichroism (difference in light absorption depending on direction of polarization) and consequently anomalous double refraction. From the ordinary dispersion theory these phenomena can be explained. The polish dichroism is due to slip of the dye particles; it is generally positive (helianthin negative) and is strongly dependent upon recryst. and moisture (cf. Zocher, *C. A.* **15**, 3576; *Ber. preuss. Akad.* **23**, 426(1925); Keeser and Zocher, *C. A.* **18**, 3511). B. J. C. VAN DER HOEVEN

The indices of refraction of some perchlorates in aqueous solution. ARRIGO MAZZUCHELLI AND ANGELINA VERCILLO. *Gazz. chim. ital.* **55**, 498-501(1925). The NH_4ClO_4 used was the same as that previously used (*C. A.* **16**, 1896). The NaClO_4 was prep'd., on account of its hygroscopicity, in conc'd. aq. soln. and the strength of the soln. was det'd. by evapg. a known portion to dryness. The HClO_4 was prep'd. according to Einster (*Z. anorg. Chem.* **52**, 278(1903)). From the data obtained the sp. refractive power in moderately dil. solns. was found to be 0.2479 for NH_4ClO_4 , 0.1844 for NaClO_4 and 0.2108 for HClO_4 . From these the mol. refractive power was calcd. to be 29.13, 22.58 and 21.18, resp. On subtracting the values for NH_4Cl , NaCl and HCl (22.53, 15.88 and 14.50, resp.) the values 6.60, 6.70 and 6.67 are obtained. These values are nearly const. and correspond to the difference between the mol. refractive power of perchlorate and Cl ions.

Relations between contraction, light refraction and light absorption in aqueous salt solutions. G. P. HÜTTIG AND MARTIN KELLER. *Z. Elektrochem.* **31**, 390-404(1925).—An extensive compilation of data on contraction, refraction and dispersion of Li halide solns. has shown that these properties afford a satisfactory measure of the deformability of the halide ions. In accordance with the predictions of Fajans and Joos (*C. A.* **18**, 1238, 2103), the deformation of I is greatest because of electrostatic attraction of neighboring ions and hence the change of these various properties with concn. is most marked for LiI. Hydration tendencies decrease in the order LiI, LiBr and LiCl.

Diffusion of light by methane and its gaseous homologs. J. CABANNES AND J. GAUZIT. *J. phys. radium* **6**, 182-98(1925); cf. *C. A.* **18**, 3529. The light transversely diffused by sat'd. gaseous hydrocarbons of the fatty series is not completely polarized. The factor of depolarization for CH_4 is 0.015 and increases regularly for C_2H_6 , C_3H_8 , C_4H_{10} , C_5H_{12} and C_6H_{14} . Present values are considerably greater than those obtained previously for air, Kr and Xe, and indicate an appreciable anisotropy of the C atom. Indices of refraction are criteria of the mean values of mol. polarization for all orientations. Lorentz' law of the additivity of refractions is applicable. A generalized form of Rayleigh's law is valid (*C. A.* **13**, 1184-5). For complete polarization, the depolarization factor $\rho = 0$.

Dispersion of light according to the quantum theory. L. S. ORNSTEIN AND H. C. BURGER. *Z. Physik* **32**, 678-80(1925).—The expression developed in a previous paper (*C. A.* **19**, 935) by means of which n for various compounds can be calcd. is put into a form which more nearly resembles the classical expression.

Rotatory dispersion of nicotine. T. M. LOWRY AND B. K. SINGH. *Compt. rend.* **181**, 909-11(1925).—L. and S. have studied the rotatory dispersion of nicotine to det. whether it is simple or complex. Their measurements show that the dispersion of nicotine is simple in the region they studied. Their results were calcd. by the formula $\alpha/\alpha_0 = 0.2379/\lambda^2 - 0.06$, where α_0 is the rotation for the green line of Hg. D. H. P.

Max Planck and the quantum theory. H. A. LORENTZ. *Naturwissenschaften* **13**, 1077-82(1925).—An excellent review of the trend of Planck's work around 1900, analyzing the thoughts leading to the quantum conception.

Quantum theory of the thermal conductivity in non-metallic crystals. YOSUTOSI

ENDO. *Nagaoka Anniv. Vol. 1925*, 67-75; *Japan. J. Physics* **4**, 3A.—The heat conduction through the non-metallic crystals was attributed to the at. oscillation. The thermal conds. were then calcd. on a quantum assumption and they were compared with Eucken's exptl. results in the case of rock salt, sylvite, fluorite and diamond. The variation of the cond. with temp. was also deduced and compared with his exptl. value.

A lesson in osmosis. J. V. JEWETT. *Gen. Sci. Quart.* **10**, 400-1 (1926).—An arrangement for school use. C. J. WEST
E. J. C.

The action of silica on electrolytes. A. F. JOSEPH. *Nature* **115**, 460 (1925).—A refutation of C. A. **19**, 1320, and a further explanation of C. A. **18**, 6. F. N. S.

The equilibrium of carbon dioxide with carbon monoxide and oxygen in the corona discharge. G. L. WENDT and MARIE FARNSWORTH. *J. Am. Chem. Soc.* **47**, 2494-2500 (1925).—CO₂ or a mixt. of CO and O₂ under the influence of the corona discharge reaches an equil. which corresponds to a decompn. of 28.54% of the CO₂. This decompn. corresponds thermodynamically to a temp. of 2600° K., although the actual temp. in the corona is little more than room temp. MARIE FARNSWORTH

Magnetism and the structure of the atom and the molecule. B. CABRERA. *J. phys. radium* 6, 241-58(1925).—C. has calcd. the at. radii of the noble gases, using Larmor's theorem and the values of Hector and Pascal for the at. susceptibilities with the following results (expressed in $h \times 10^8$) He, 0.57; A, 0.85; Kr, 1.03; Xe, 1.44. Ionic radii are also calcd. from magnetic data for ions of the argon type from P^{---} to Ca^{++} . These numbers are in good agreement with those deduced by Fajans, Herzfeld and Grimm from crystal lattice data using Born's theory. The nos. for the noble gases correspond to about half the resp. values obtained from kinetic theory, as they should. The moment of inertia of Sommerfeld's (cf. *C. A.* 17, 2990) H_2 mol. model from magnetic data is 1.6×10^{-40} . Expt. has shown that the nature and distribution of electronic orbits in the atom are always such that the resultant magnetic moment is a certain multiple of the Weiss magneton. This does not prevent the orbit having a magnetic moment equal to a no. of Bohr magnetons corresponding to its azimuthal quantum no. In order to explain the effect of temp. on paramagnetism, it is suggested that the orientation of the magnetic axis of the atom takes place through a reorganization of the outer electronic orbits after perturbations caused by at. collisions from thermal agitation. II. *Ibid* 273-86.—It is found that the data on paramagnetism in the iron group and the rare earths agree fairly well with the electronic distribution scheme of Stoner. The connection between the magnetic behavior of the ions and the formation of complexes of the Werner type is discussed. The const. Δ of the Curie law is made to depend on the action of neighboring atoms on the paramagnetic atom under consideration.

A theory for the excitation by collisions of atoms and molecules. M. BORN, P. JORDAN AND L. NORDHEIM. *Naturwissenschaften* 13, 969-70(1925).—The authors give a rough outline on the developments of a new theory (to be published in *Z. Physik*) for the prediction of the possibility of quantum jumps occurring on mutual collision of atoms or mols. based on the elec. charge distribution inside the particles, smallest distance of approach, etc. The orbits of the atoms are considered to be linear. By means of the Born/Jordan (*C. A.* 19, 3211) treatment of aperiodic phenomena a classical expression is developed for the energy liberated on collision of the 2 systems. From this is found the probability for a quantum jump $\varphi_{\tau\sigma}^{\pm} = 1/h^2 \sum_n (\Gamma_{\tau} \Gamma_{\sigma})_{\pm}^n G_n$, in which Γ

represents a function of the elec. dipole moments inside the atoms τ and σ , G_n depends upon the orbits of the atoms (their smallest distance and relative velocity); the summation is due to a series development, expressing the influence of elec. moments of higher order. For the translation of the classical functions into quantum rules use is made of the reversibility condition of the Maxwell distribution law (along the lines of the Klein-Rosseland theory). Those processes are most probable in which both colliding particles experience a quantum change. H and H_2 are the most active particles; noble gases are very little active, particularly the light ones.

The K absorption levels of the light atoms: A correction. H. ROBINSON. *Nature* 115, 945-7(1925).—The deduction of ν/R values from measurements of a number of "soft" X-ray absorption levels gave results which agreed very well with values deduced from spectroscopic X-ray data, but fairly wide systematic deviations were observed in the case of the K levels of the light atoms (cf. *C. A.* 19, 623). R.'s values were appreciably higher than those previously accepted. By extending the series of measurements of corpuscular spectra R. obtains 36.7 for the value of ν/R of the oxygen K level instead of the former value of 42.3. Values of ν/R K level for the light atoms are re-detd. and given. R. attributes the error in the earlier expts. to the moving of the Helmholtz coils.

Structure of the nucleus of radioactive atoms, and the emission of ray-spectra. JEAN THIBAUD. *Compt. rend.* 181, 857-9(1925).—A quantum hypothesis of nuclear constitution which involves a very condensed central part of positive charge Ne , (N at. no.), giving rise to a central force of the form $F = (Nc^2/r^2)[1 - (b(a-2)/r(a-2))]$, where r is the radial distance from the nuclear center. Around this center gravitate in quantized orbits positive particles which emit γ -ray quanta in interorbital transitions.

Using the values $a = 3$, $N = 100$, $b = 3.29 \times 10^{-12}$ and supposing the emitting particle to be a proton, T. calcs. the term energies of such a system and compares the resulting combinations with the observed γ -ray spectrum of meso-Th. The agreement is satisfactory.

NORRIS F. HALL

The structure of light. J. J. THOMSON. *Phil. Mag.* **50**, 1181-96(1925).—This paper develops further the theory of light previously outlined by T. (C. A. **19**, 211). Light is assumed to have a two-fold structure, one part consisting of waves of the same character as postulated in the electromagnetic theory. These waves may be regarded as a periodic distribution of closed lines of elec. force like those of a Hertz oscillator. The other part of the structure of light is assumed to be corpuscular, or closed lines of elec. force which travel through space without change of shape instead of expanding as do the light waves. The effects which would follow from collisions between quanta and electrons are discussed. The quanta would be deflected and lose frequency by colliding with electrons. This deflection would cause a scattering of the light made up of a great number of small deflections combined according to the theory of probability; this in addition to the scattering accounted for by the wave theory which is proportional to $(1 + \cos^2)$. The theory indicates that when the electrons are in rapid motion collisions between the quanta and the electrons will produce an increase in the frequency of some of the quanta.

S. C. L.

A new type of gaseous catalysis. S. C. LIND AND D. C. BARDWELL. *Science* **62**, 593-4(1925).—It is found that the ions of inert gases such as He, A, Ne and N_2 are effective in accelerating polymerization of C_2H_2 , HCN, C_2N_2 and the synthesis of H_2O , although they do not enter chemically into the reaction. The ions are produced by α -particles from radon (Rn). This effect is given the name "ionic catalysis" and is added to the usual polymerizing effect of the ions of the reactants.

D. C. B

The radioactivity of the mineral waters of Hammam Meskoutine (Algeria). I. POUGET AND D. CHOUGHAK. *Compt. rend.* **181**, 921-3(1925); cf. C. A. **19**, 3214.—The radioactivity of several of the hot mineral waters in this district is given. It varies from zero to 13.7 millimicrocuries per l.

MARIE FARNSWORTH

Millikan rays and the acceleration of radioactive change. A. W. C. MENZIES AND C. A. SLOAT. *Science* **63**, 44-5(1926).—The objection that the energy associated with high voltage falls far short of that associated with changes in the nucleus does not apply to the Millikan rays. It is suggested that expts. on the possible acceleration of radioactive change by these high-frequency radiations would be of great interest.

MARIE FARNSWORTH

The decomposition period of radium E. GEORGES FOURNIER. *Compt. rend.* **181**, 502-4(1925).—Ra E was prepd. from Pb contg. a mixt. of Ra D + E and its activity measured with a quartz piezoelectrometer; the period of 2 samples of Ra E was found to be 4.86 days and of one sample 4.84 days. This value agrees with 4.85 days given by Thaller in 1912 and not with the value 4.98 recently detd. by Bastings.

MARIE FARNSWORTH

The special action of the sun on the radioactivity of lead and uranium. MLLE. ST. MARACINEANU. *Compt. rend.* **181**, 774-6(1925); cf. C. A. **18**, 1812.—Pb, previously inactive, when exposed to the sun exhibits an activity which manifests itself by its effect on a photographic plate and on ZnS, and by an ionization current. The activity of U becomes very irregular after exposure to the sun.

M. F.

Absorption of beta rays by matter. (MME.) J.-S. LATTES AND GEORGES FOURNIER. *Compt. rend.* **181**, 855-6(1926); cf. C. A. **19**, 1530, 1986, 2297.—The mass coeff. of absorption μ/ρ of the secondary β -radiation produced in C, Al, Ag, Pt, Au and Pb by the primary γ -rays of Ra was found to vary with N , the at. no. of the absorbing element, according to the law $\mu/\rho = a + bN$, where for these 6 elements, $a = 5.73$ and $b = 0.0547$. It is found that a/b is const. and $= 105$, not only for these secondary rays but also for both the hard and soft primary β -rays of Ra E, although a and b have different values for these rays. It is concluded that some function of an emission potential enters as a factor into the μ/ρ for all such rays.

NORRIS F. HALL

The number of particles in the β -ray spectra of radium B and radium C. R. W. GURNEY. *Proc. Roy. Soc.* **109A**, 540-61(1925).—The β -rays emitted from Ra B + C were analyzed by deflecting them into a spectrum with a magnetic field. The deflected rays were focused on a slit over a Faraday cylinder, the rate at which it charged giving the no. of electrons passing through the slit, provided the solid angle of the beam of rays is known. The exptl. conditions were varied for the purpose of detg. whether the continuous spectrum of Ra B + C is genuine or is an unresolved line spectrum. The evidence obtained shows that both Ra B and Ra C emit a genuine continuous spectrum of β -rays attributable to the electrons ejected from the nuclei of the disinte-

grating atoms. The spectra are illustrated with curves showing the rate of charging the Faraday cylinder with varying field strengths. Superposed on the curve for Ra B are peaks corresponding to its characteristic β -ray lines. These are due to electrons ejected by the absorption of γ -rays emitted from the nucleus. By measuring the peaks the actual no. of particles in the intense β -ray lines may be obtained, from which it is concluded that the probability of a γ -ray being converted instead of escaping from the radioactive atom is 1 to 7. The heating effect of the β -rays of Ra B + C is found to be 5.6 cal. per hr. per g., of which 1.3 cal. is contributed by Ra B and 4.3 cal. by Ra C.

C. C. KIESS

Determination of the decay constant of actinium A. HAZIME IKEUTI. *Nagaoka Anniv. Vol. 1925*, 295-300; *Japan. J. Physics* 4, 13A.—It was previously shown (C. A. 16, 3433) that when An (Ac Em) is introduced into the cloud chamber of a Wilson condensation app. and the tracks of the α -rays emitted by it, and also by its product Act A, are made visible by the usual method, most of them appear in pairs having common heads. Considering that the α -rays emitted during the effective intervals τ_1 and τ_2 before and after a certain moment, resp., at which condensation begins to take place, should result in diffuse and sharp tracks, the nos. of the pairs of tracks in the 3 different modes—diffuse-diffuse, sharp-sharp and diffuse-sharp—and those of single tracks—diffuse and sharp—were shown to be given by functions of the total no. of the tracks, the tracks τ_1 , τ_2 and the decay const. λ of Act A. In the present expts., the decay const. was deduced from the nos. of tracks in the above different modes and the length of the intervals τ_1 and τ_2 . The method by which the values τ_1 and τ_2 were detd. consists essentially in registering the time, at which α -rays passed through the chambers, on a photographic plate falling at a known speed, on which the motion of the plunger at expansion was simultaneously recorded, while the appearance of the tracks was being observed visually or recorded photographically. The value of λ obtained was 474 sec.⁻¹, to which corresponds a half value period of about 1/700 sec.

C. J. WEST

Theory of the range of α -particles. LEONARD B. LOEB AND EDWARD CONDON. *J. Franklin Inst.* 200, 595-608(1925).—Fowler's (C. A. 17, 3828) and Bates' (C. A. 19, 775) measurements have shown that the theoretical values derived on the basis of the quantum theory for the range of α -ray particles by Henderson (C. A. 17, 21) are too high. The stopping power calcd. is from 0.6 to 0.8 of the observed values in He, Ne, A, Kr and Xe. L. and C., taking into consideration the second ionization of the same atom, which may occur as soon as p_R (radius of the cylinder around the α -ray path, inside which ionization can take place) becomes of the order of the at. dimensions (for He and probably for A), calc. the error introduced in Henderson's values due to this effect (cf. Rosse-land C. A. 17, 1376). Whereas the exptl. range in He is 23.6 cm., Henderson's calcd. range 33.0 cm., L. and C. find a corrected range of 58 cm. From the increased discrepancy it is concluded that the calcn. of ranges by application of quantized energy changes to classical dynamical treatment is inadequate for He, very likely also for other gases, apparently because the assumption, that the electron is at rest and responds freely.

B. J. C. VAN DER HOEVEN

H. Petterson's explosion theory of atomic decomposition. E. CHALFIN. *Naturwissenschaften* 13, 969(1925).—According to Petterson (C. A. 18, 2103) the energy of the H particles ought to be independent of the energy of the incident α -particles. From Rutherford's measurements, however, follows an almost const. difference between the two for N₂ as well as for Al. According to Petterson one may expect a velocity of the nucleus after the impact calculable from $v_{\text{nucleus}} = 4v_{\alpha}/(A + 4)$, in which A is the at. no. This equation is exptly. verifiable by taking v_{nucleus} as the difference Δv_H between the velocities of emitted H particles parallel and perpendicular to the α -ray. The agreement for Be, C, Si is fairly good, but large discrepancies are found for N, F, Na, Al and P; of the first three elements the v_H values are too uncertain to consider this as sufficient support of P's theory.

B. J. C. VAN DER HOEVEN

Theory of the luminosity of canal rays. J. PALACIOS. *Anales soc. españ. fis. quim.* 23, 477-95(1925).—A theory is developed for the phenomenon of excitation and ionization of a canal ray when passing through gas at rest. It involves the av. distance between two collisions, the time of arrest in the Bohr orbits and the probabilities of different transitions, and calcs. the no. of atoms which in the stationary state are found ionized and in the different states of excitation. A comparison with the Wien theory permits pointing out the hypotheses he made which have been criticized as regards accuracy. All possibilities regarding time of emission are considered and it is shown that the instantaneous emission (from the light quantum) is more probable. Application of this theory to the case of canal rays propagated *in vacuo*, show that the Wien measurements on amortization of spectral rays could be interpreted with the light

quantum if it is admitted that there exists in the Bohr atom some orbits whose stability is greater than others. These considerations allow prediction of the amortization of luminosity curves of some spectral rays not yet studied. It can be seen how the principle of correspondence is in accord with the very great stability of the exterior orbits.

E. M. SYMMES

The critical potential of the negative band spectrum of nitrogen. E. E. WITMER. *Phys. Rev.* **26**, 780-5(1925).—Evidence is given that the negative bands of N_2 appear at the ionization potential of nitrogen or between the ionization potential and 17.75 v.

D. C. BARDWELL

Striated discharge in hydrogen. ARTHUR BRAMLEY. *Phys. Rev.* **26**, 794-9 (1925).—A study was made of the potential distribution, electron concn., and mean electron energy at eleven points in a discharge tube, by means of Langmuir's probe method.

D. C. BARDWELL

The ionization of nitrogen by electron impact as interpreted by positive-ray analysis. T. R. HOGNESS AND E. G. LUNN. *Phys. Rev.* **26**, 786-93(1925); cf. *C. A.* **19**, 3062.—At pressures less than 10^{-6} mm., only N_2^+ was observed. As the pressure increased the % of N_1^+ increased regularly to 60% at 0.006 mm. The percentage of N_1^+ was markedly greater in the presence of He. Below 24 v. no N_1^+ ions were produced, although N_2^+ ions appeared when voltage exceeded 17 v. It is concluded that two types of N_2^+ are formed in the primary process; at potentials greater than 24 v., and an unstable type which reverts to N_1^+ upon collision with mols. at less than 24 v. and greater than 17 v. The N_2^+ formed is stable with regard to collisions. The structure of the two types of ions is suggested in accordance with the G. N. Lewis theory. N_2^- ions were found in concns. too weak to study.

D. C. BARDWELL

The low-voltage arc in oxygen. L. L. LOCKROW. *Phys. Rev.* **23**, 553-4(1924).—The lowest potential of arc maintenance in O_2 is 16.1 v. At 22 v. the spectrum shows negative bands, some triplet system lines and one singlet system line at 4368 Å. U.

F. O. A.

The discharge of electricity between equipotential plates. M. E. HUFFORD. *Phil. Mag.* **50**, 1197-214(1925).—H. has investigated the phenomena accompanying the discharge in different gases at low pressure between a plate anode and a two-plate equipotential cathode, of which the one nearest the anode has a hole in the center for the passage of positive ions. By means of a probing electrode the voltage drop was detd. at different points between the equipotential plates. The conditions found in various gas mixts. are shown in a large no. of graphs. The two most striking phenomena are the presence of a bright bead passing through the hole in the nearest cathode plate, and a glow which then fills the entire space between the two cathode plates. A magnet showed the presence of electrons in this space. Current-voltage relations were detd. When the walls are covered with sputtered metal the bead could not be produced.

S. C. L.

The diffusion back, reflection and secondary radiation excitation of slow cathode rays. A. BECKER. *Ann. Physik* **78**, 253-76(1925).—B. measures the exit velocities of electrons which leave a pure or sooted Pt surface in a definite direction when radiated with slow cathode rays (10-1100 v.). The velocity distribution curve shows 3 parts (1) there is a quick decrease, then (2) a slow decrease and (3) a quick decrease. (3) corresponds to true reflection and occurs for electrons of velocities up to 12 v. For higher velocities or greater angles, the reflection decreases and secondary radiation (1) occurs. The velocity distribution of the latter does not depend on the emission direction for primary velocities above 100 v. (2) corresponds to electrons which have penetrated the surface and diffused back, losing 5 v. on the way.

D. S. VILLARS

The velocity of secondary cathode radiation. A. BECKER. *Ann. Physik* **78**, 228-53(1925).—The velocity distribution of secondary cathode rays excited by homogeneous primary rays of 24 to 1075 v. falling on a sooted metallic surface, is the same as for δ radiation; i. e., is the consequence of an inner Maxwellian distribution overcoming a surface force on exit from the surface. The most probable exit velocity, (2 v.) is independent of the primary radiation velocity so long as this is above 24 v. Thus the secondary radiation velocity is an at. const. and the variation in this velocity with the energy of the primary cathode rays found in the older expts. is evidently due to a secondary process. This all agrees with Lenard's critique of the older literature (cf. Lenard, *Quantitatives*, p. 160).

D. S. VILLARS

The velocity loss in metals of moderately fast cathode rays, from direct measurement and absorption experiments. A. BECKER. *Ann. Physik* **78**, 209-27(1925); cf. Baeyer, *C. A.* **6**, 2576; Terrill, *C. A.* **18**, 15; and Becker, *C. A.* **19**, 931.—Homogeneous cathode rays of const. initial velocity 0.52 times that of light undergo on passing

through Al foil of thickness, 0.0045, 0.0090, 0.0135, 0.0180, 0.0224 and 0.0280 a relative velocity loss of 1.5, 3.5, 5.6, 8.2, 10.6 and 14.4%, resp. For equal masses the loss in Al and Pt is nearly the same; in Au it is smaller. The exit velocities from the thicker layers are less homogeneous. The above values were obtained directly from micro-photometric measurement of photographs of magnetic deviation of the electrons. The absorption measurements show a strong increase in absorption coeff. with increasing layer thickness. This corresponds to the slowing down in the metal and the estd. velocity loss agrees satisfactorily with the direct observations.

D. S. VILLARS

The photoelectric effect due to the total radiation from solids. A. BECKER. *Ann. Physik* **78**, 83-111(1925).—Exptl investigation of the photoelec. excitation of Al by the total radiation of W at 2100-3200° abs. leads to the following conclusions: (1) the no. of photoelectrons is $n = \text{const.} \times \theta^{\alpha} e^{-c_2/\lambda\theta}$ where θ is the abs. temp. of the radiator, α has a value of 3-4, c_2 is a const., and λ_0 is the wave length of the spectral limit of the total radiation; (2) the velocity distribution and most probable emergent velocity of the photoelectrons are the same as those of the thermionic electrons of the radiator. There is a complete parallelism between photoelec. effect and thermionic activity of a temp. radiator. Theoretical summation of the individual photoelec. processes in infinitely small spectral regions leads to no conflict with exptl. data. These individual processes are independent of one another. The photoelec. sensitivity distribution of metals, i. e., the mass of electrons set free per unit of absorbed energy of wave-length λ , may be represented by the formula: $f(\lambda) = \text{const.} \times (1 - \lambda/\lambda_0)^a$ where a is 2 or 3, depending upon the phys. condition (gas content) of the metal.

R. J. HAVIGHURST

New researches with the Crookes tube. A. DAUVILLIER. *Compt. rend.* **181**, 691-3(1925); cf. *C. A.* **19**, 3424.—Expts. are made to det. the origin of gas evolution from the walls of X-ray bulbs and the Crookes dark space. Specimens of various glasses were subjected to homogeneous cathode rays in a very high vacuum. After irradiation of 1/2 hr. the green fluorescence due to Mn disappeared and the glass assumed a violet-brown color. This color change is coincident with the release of gas which is adsorbed chem. on the walls. D. demonstrates, further, the existence of positive emission in the "secondary dark space" produced by impact of cathode rays on the glass surface.

H. R. MOORE

The compound photoelectric effect. PIERRE AUGER. *J. phys. radium* **6**, 205-8 (1925); cf. *C. A.* **19**, 2776.—Photographs obtained with C. T. R. Wilson's cloud method reveal spurs which indicate the emission by the same atom of a series of photoelectrons of diverse velocities. A beam of 20-100 kv. X-rays was projected into the gases N, O, Cl, A, Br, Kr, I, Xe of increasing at. no. White points and short tracks were obtained in all cases, showing the emission of secondary electrons. With A the length of these paths was increased by adding H₂. Tertiary rays were frequently secured. Br and Xe gave quaternary emission, and Xe showed evidence of emission of a fifth electron of relatively small energy. The process is analogous to radioactive disintegration. The energy liberated by electronic transition in a lower K level is transferred wholly to one or more electrons in the same atom.

H. R. MOORE

Soft X-rays from certain metals. C. T. CHU. *J. Franklin Inst.* **200**, 615-27 (1925).—In a vacuum tube are sealed a filament, an anode of the material (Ni, Fe and Cu), being examd., and a photoelec. disk (Ni); the last 2 elements are sepd. from each other by an ion trap, consisting of a metal cylinder with axial wire. The radiation from the anode can reach the photoelec. target only under a very small solid angle; this improves materially the sharpness of the measurements. On bombarding the anode with electrons of varying speed, electrometer readings of the charge of the target indicate the radiation emitted by the anode. Breaks in the curve, indicating voltage threshold values for certain radiations, were found to occur for Ni at 49, 75 and 98 v., for Fe at 52, 68 and 80 v., for Cu at 30, 49, 62, 79 and 90 v. The values of corrections to be applied (0.5 v.) are immaterial; the 49 and 52 v. values may all be due to the Ni target. The necessity for further work is emphasized; the existing rather unreliable and little concordant data are tabulated.

B. J. C. VAN DER HOEVEN

Some properties of Compton radiation. H. KALLMANN AND H. MARK. *Naturwissenschaften* **13**, 1012-5(1925).—A preliminary report, to be published in *extenso* in *Z. Physik*. On radiating Li powder with a pencil of ZnK α doublet light, K. and M. found that of the dispersed ray, observed under an angle of 90° with the incident ray both the waves of original frequency and of the shifted Compton effect frequency were linearly polarized. The distribution of intensity over the Compton-effect radiation in different directions does not show selective interference maxima. A bibliography is added.

B. J. C. VAN DER HOEVEN

Reflection and refraction of X-rays. M. SIEGBAHN. *J. phys. radium* 6, 228-31 (1925); cf. *C. A.* 19, 1660.—If the frequency of the X-ray used $\nu > \nu_n$, the own frequency of resonators in the reflecting crystal, the following equation holds for the n th-order reflection: $n\lambda = 2d_0[1 - 4k(d_0^2/n^2)] \sin \varphi_n$, lattice const. is d_0 , k is a const. independent of λ . S. verified this relation by plotting $\sin \varphi'/\sin \varphi = d_{\text{calcite}}/d_{\text{gypsum}}$ as a function of λ . Two marked discontinuities from a straight line, parallel to the λ axis were found, corresponding to CaK and SK radiations, i. e., an ordinary anomalous dispersion effect. Refraction and total reflection of X-rays is shown to occur also for amorphous substances. With a glass prism ($d = 2.551$), using a thin pencil of Fe, Cu or Mo radiation, values were found for δ ($= 1 - \text{index of refraction}$), $\lambda = 1.933$ A. U., $\delta = 12.38$ ($\times 10^{-6}$); 1.750 A. U., 10.00; 1.538 A. U., 8.125; 1.389 A. U., 6.648; 0.708 A. U., 1.641; 0.630 A. U., 1.220. Due to the small proper frequencies of the glass resonators δ/λ^2 was found to be const. This method of measuring X-ray reflection is completely analogous to the optical one and may become of great importance for several purposes.

B. J. C. VAN DER HOEVEN

Standard measurements of wave lengths in the X-ray range. MANNE SIEGBAHN AND ELLIS HALMAR. *Arkiv. Mat. Astron. Fysik* 19A, No. 24, 12 pp. (1925).—New measurements with very great precision give for the wave length of Cu $K\alpha_1$ 1537.259 X. U. with the vacuum spectrograph and 1537.265 X. U. with a new tube spectrograph. In order to show the accuracy by the distribution of separate measurements around av. values the detailed results of these 2 series of expts. the measurements of Leide and of Lang on the same wave length, the relative measurements of Weber on Zn $K\alpha_1$ and the various measurements of the Na D_1 line are compared graphically on vertical scales expressing the same percentage deviation. The new measurements are so precise that they far surpass all previous efforts to obtain abs. values in either the X-ray or optical regions.

GEORGE L. CLARK

Experimental research on departures from Bragg's law with mica crystals. AXEL LARSSON. *Arkiv. Mat. Astron. Fysik* 19A, No. 14, 10 pp.—Precision researches by the Siegbahn method on the reflection of Cu $K\alpha_1$ rays by mica crystals verify the Ewald formula expressing correction to the Bragg law $\log \sin \phi_n/n = C + A/n^2$, where ϕ_n is the angle in the Bragg equation $n\lambda = 2d \sin \phi_n$ and C and A are consts. The theoretical value of A derived from the characteristic frequencies of the dipole lies between 6.2×10^{-4} and 7.5×10^{-4} . The exptl. value is 6.3×10^{-4} . Calcns. of departure from Bragg's law as a refraction phenomenon are also in agreement with the exptl. results. The Ewald equation $n\lambda = 2d[1 - 5.4 \cdot \rho d^2/n^2 \cdot 10^{-6}] \sin \phi_n$ is, therefore, approx. correct.

GEORGE L. CLARK

The time lag of X-rays. FRITZ KIRCHNER. *Ann. Physik* 78, 277-304 (1925).—The time between the absorption of an X-ray of about 2 A. U. which the K radiation of Fe affords and the emission of a photoelectron is smaller than $1/\alpha = 4 \times 10^{-10}$ sec. The time between the absorption of a primary cathode ray and the release of a secondary electron has the same upper limit. The yield in photoelectrons by X-rays is independent of the subdivision of illuminating time down to 10^{-9} sec. Photoelectrons driven back by an elec. field into the metallic surface from which they came do not disappear instantaneously but there is a time lag of the order of 10^{-9} sec. These results were obtained by using an improved Wiechert method for direct detn. of cathode-ray velocities.

D. S. VILLARS

The asymmetry of the discharge of Röntgen electrons. II. W. SEITZ. *Physik. Z.* 26, 610-5 (1925); cf. *C. A.* 18, 1238; 19, 777.—Further expts. are recorded including rays from Cu produced by X-rays from Ag filtered by Pd, from Ag by X-rays from Mo and from Pb by X-rays from Ag. The rays were sepd. magnetically and received on a photographic plate. The intensity was measured by a self-registering photometer which included a thermopile and galvanometer with record on photographic paper. Certain of the maxima are interpreted in terms of various combinations of X-ray energy.

F. O. A.

A method permitting the following, by means of X-ray spectra, of certain chemical reactions (oxidation of non-saturated fatty acids). JEAN-JACQUES TRILLAT. *Compt. rend.* 181, 504-6 (1925).—Remarkably intense X-ray spectra are obtained from thin layers of fatty acids on a metal plate, by the method of the turning crystal. Oleic acid, deposited on a Pb plate first gives a spectrum corresponding to $d_1 = 29.8$ A. U. After several hrs. a new spectrum appears, $d_2 = 37.5$ A. U. The first spectra corresponds to lead oleate and the second to the satn. of the double bond by O. After about 40 hrs. the compd. polymerizes and does not give spectra. Analogous results were obtained for linoleic acid: $d_1 = 37.1$ A. U. and $d_2 = 49.2$ A. U., the 2 double bonds being satd. simultaneously. With linolenic acid 3 spectra were obtained: $d_1 = 21.2$ A. U.,

$d_2 = 28$ A. U. and $d_3 = 34.44$ A. U. In this case the spectrum of the lead salt was not obtained and the 3 spectra correspond to the taking up of O_2 at the 3 double bonds.

MARIE FARNSWORTH

The excitation of the spectra of nitrogen by electron impacts. D. C. DUNCAN. *Astrophys. J.* 62, 145-67(1925).—The band spectra of N were excited by low-voltage arcs maintained in tubes with two or three electrodes for the purpose of detg. the excitation stages of the various spectral features. The region studied extended from wave length 7000 A. U. to 2000 A. U. in the ultra-violet. Below the ionization potential the bands which appeared were the first, second and fourth positive groups, and three new groups which are designated as the fifth, sixth and seventh positive groups. The wave-length data for the new bands, all of which lie in the ultra-violet, are tabulated. The negative bands appear only above the ionization potential and increase in intensity as the no. of ionized mols. increases. A new group of negative bands was observed in the ultra-violet and has been called the second negative system. The frequency differences derived from the measured wave lengths show that these new bands are related to the first negative group of bands. The existence of additional bands in the extreme ultra-violet is indicated by the fact that in the emission of the bands just described the N mol. is not brought back to its normal state. Since, in this work which was done with very pure N, the third positive group and the cyanogen bands did not appear, it is concluded that they do not belong to N alone, but perhaps to compds. with other elements. The excitation potentials at which the different band groups appear are tabulated.

C. C. KIESS

Colored photographs of line spectra. CL. SCHAEFER AND C. BORMUTH. *Physik. Z.* 26, 697-8(1925).—A description is given of color photographs of various line spectra to be used as lantern slides for lecture demonstrations. Agfa color plates were used for the purpose and it was found that they reproduce the spectral colors very well except in the region of the yellow Hg line at 579μ , which the plate reproduces as green, although the Na line 589μ was reproduced in its true color. Spectrophotometric measurements of the red, green and blue grains of the color plate showed that in the short interval between the Na and Hg lines the red grains decreased rapidly in transparency so that for the Hg line the red and green grains were not in the correct proportion to give a true color reproduction.

C. C. KIESS

The absorption spectra of some crystals of the rare earths and their modification in a magnetic field at the temperature of liquid helium. JEAN BECQUEREL, H. KAMEKLINGH ONNES AND W. J. DE HAAS. *Compt. rend.* 181, 758-60(1925).—The absorption spectra of four uniaxial crystals, xenotime, tysonite, bastnaesite and parisite, were observed at various low temp. stages down to 4.2° K. (liquid He). These crystals, very rich in absorption bands at 80° K., exhibit much simpler absorption at 14° K. At 4.2° K. the spectra are even less complex. A few bands, appearing feebly only at low temp., increase in intensity at 4.2° K. When the crystals are placed in a magnetic field with their axes parallel to the lines of force, marked dissymmetries in intensity of the bands appear as observed with and against the lines of force.

C. C. KIESS

Interpretation of the hydrogen and helium spectra. J. C. SLATER. *Proc. Nat. Acad. Sci.* 11, 732-8(1925).—Evidence is presented to substantiate the conclusion that the spectra of H and He resemble, resp., those of the alkalis and alk. earths. For He the resemblance to the alk. earths is based on similarity of term multiplicity and term character as required by the Zeeman effect. For H and He⁺ the resemblance to the alkalis is traced through the fine structure and Zeeman effect.

C. C. KIESS

Radiation emitted by optically excited zinc vapor. J. G. WINANS. *Proc. Nat. Acad. Sci.* 11, 738-42(1925).—Light from a Zn arc *in vacuo* was passed through a heated quartz tube contg. Zn vapor and called the resonance tube. In a direction perpendicular to the exciting beam the resonance tube was observed to emit the first member of the sharp series of the singlet system, the first and second members of the diffuse series and the first member of the principal series of the triplet system, and an intersystem line. That the exciting wave lengths were shorter than 3200 A. U. was proved by the non-appearance of the resonance lines when a plate-glass screen was placed in the path of the exciting beam. In addn. to the line spectrum of the atom a system of bands is also excited in Zn vapor. Wave lengths for 12 bands between 4301 A. U. and 2952 A. U. are given.

C. C. KIESS

Complementary researches on the structure and distribution of band spectra. H. DESLANDRES. *Compt. rend.* 181, 410-2(1925).—A new and special law of force which governs at very small distances the mutual reactions between the elec. charges of an at. nucleus is supposed to be the cause of intra-nuclear oscillations represented by

the const $d_1 = 1062.5$, which has been found to be a characteristic fundamental frequency of band and line spectra (C. A. 20, 14) C. C. KIESS

The behavior of benzene in the presence of aqueous solutions; the ultra-violet absorption as a function of p_H . FRED VLÈS AND MADELEINE GEX. *Compt. rend.* 181, 506-9(1925); cf. C. A. 19, 3427.—The ultra-violet absorption spectra of aq. benzene solns. are examd. In plotting p_H against ϕ , the ratio of the absorption consts. of 2 spectral lines which vary dissimilarly, sinuous curves are obtained, showing that benzene is not inert in respect to the H-ion concn. of the soln. Several different interpretations of the curves are given. MARIE FARNSWORTH

The spectrum of rubidium at low voltages. F. H. NEWMAN. *Phil. Mag.* 50, 1276-82(1925).—By applying voltages of 1.7-4.2, N. has obtained the line-by-line spectrum of Rb. A diagram of the possible electron shifts in the Rb atom is shown, and the wave lengths are given for 8 shifts, 7 of which are doublets. Comparison is made of the voltage which has to be applied to produce each line with the theoretical one. While agreement is fair the applied voltages are uniformly higher, in some instances as much as 0.4 v (cf. C. A. 19, 3215) S. C. L.

The absorption spectra of several ketones. (Reply to J. Plotnikov.) S. L. LANDELIK. *Rec. trav. chim.* 44, 931 4(1925). (In German.) —A reply to P.'s criticisms (C. A. 19, 3427) of L.'s earlier paper (C. A. 19, 2301). E. J. WITZEMANN

The influence of the p_H upon the ultra-violet absorption spectra of certain cyclic compounds. WILHELM STENSTROM AND MELVIN REINHARD. *J. Phys. Chem.* 29, 1477-81(1925).—Spectrophotometric observations of aq. solns. of phenol, tyrosine, resorcinol, *p*-hydroxybenzoic acid, salicylic acid and *p*-hydroxybenzaldehyde showed that the positions of their ultra-violet absorption bands between 3600 and 2200 Å are dependent upon the H-ion concn. For aq. solns. of benzoic acid, phenylalanine and tryptophan the positions of the bands were apparently independent of the p_H . When the solns. are made alk. by adding NaOH or other alkalies the bands shift toward the red and become more intense when a certain alk. has been reached. The compds so affected are those with a OH group in the benzene ring. For phenol, tyrosine and resorcinol curves are given which show the shift in wave length with p_H for definite extinction coeffs. The shifts are explained as a change in the absorption of neutral mols. and of mols. ionized at the carboxyl group. C. C. KIESS

Some remarks on primed terms in the spectra of the lighter elements. OTTO LAPORTE. *J. Wash. Acad. Sci.* 15, 409-13(1925).—Recent theoretical work by Heisenberg (C. A. 19, 3064) and by Hund (C. A. 20, 18) has shown that the quantum no which is related to the term character $S = 1, P = 2, D = 3, F = 4$, etc., is not the azimuthal quantum k of the last bound electron, but is the resultant l of the angular momenta of all the valence electrons obtained by space quantization. Hund's work shows that the arc spectrum of an element is built up from the spectrum of the ionized atom, that is, only those terms appear in the arc spectrum which can be derived from those of the first spark spectrum by the addition of one more electron to the atom. These principles permit the deduction of the correct electron configuration responsible for the appearance of the ($^2PP'$) group of Si II and the similar groups (C. A. 19, 2781-2, 3217) of Bowen and Millikan for Al, P III, S IV, Cl V and C II, N III, O IV. Likewise a similar derivation gives the ($^3PP'$) groups of Mg I, Al II, etc., and of Ca I, Sr I, Ba I and the spark spectra analogous to them; and the term separations ΔP and $\Delta P'$ can be explained accurately on the basis of Heisenberg's formula. C. C. K.

Correlation of absorption spectra with ionization in violuric acid. R. A. MORTON AND A. H. TIPPING. *J. Chem. Soc.* 127, 2514-7(1925).—The disson. const. of violuric acid at 18° is 1.992×10^{-5} . Absorption was detd. photographically with a sector photometer in approx. 0.01 M soln. with varying amts. of HCl. Dissoc. was calcd. from K and the p_H measured by a quinhydrone electrode. Mol. extinction coeff. for the ion is 60. Results in alk. soln. were less accurate, but in approx. agreement. The head of the absorption band in the visible is at 538 m μ ; there are also bands at 250 m μ ascribed to the undissocd. mol. and at 312 ascribed to the ion. B. H. CARROLL

Ultra-violet absorption spectra of the butenonitriles and their analogs. P. BRUYLANTS AND A. CASTILLE. *Bull. soc. chim. Belg.* 34, 261-84(1925).—The ultra-violet absorption spectra of solid MeCH:CHCO₂H, MeCH:CHCN (b. 108°), and MeCCl:CHCO₂H (m. 94°) are all continuous, while *iso*-MeCH:CHCO₂H, MeCH:CHCN (b. 121°), and *iso*-MeCCl:CHCO₂H (m. 61°) all have spectra quite sharply inflected near the lower end, this establishing definitely the stereochem. equivalence of solid MeCH:CHCO₂H and the lower m. MeCH:CHCN isomer (for identity of their thermochem. characteristics (cf. C. A. 19, 2324). The isomerization of CH₂:CHCH₂CN to MeCH:CHCN and of CH₂:CHCH₂CO₂H to MeCH:CHCO₂H, both in dil. alk.

soln., have been studied through the absorption spectra of the alk. solns., but little new information was gained. Spectra are given for trimethylenecarboxylic acid and its nitrile, and are compared with those of the corresponding vinylacetic and crotonic compds. from the standpoint of their chem. constitution; the vinylacetic compds. lie between the other 2 as regards intensity of the absorption. WM. B. PLUMMER

Note on the $L_{II}L_{III}$ levels of the atoms silicon, phosphorus, sulfur and chlorine. S. K. ALLISON. *J. Wash. Acad. Sci.* **16**, 7-10(1926).—By application of the combination principle it is possible to calc. the energy values of the $L_{II}L_{III}$ levels in the atoms Si, P, S, Cl, in various compds. from recent X-ray data. The resulting values are compared with a detn. of these levels in the hydrides of these atoms carried out by Holweck by photoelec. methods. The results show that for Si, P, S, these levels have very nearly the same energy in the hydrides as in the elementary substance itself, but that in the higher oxides of these elements there is an appreciable difference in this respect between the elements and their oxides. S. K. ALLISON

The experimental determination of the relative intensities of some of the molybdenum and copper K-series lines and the tungsten L-series lines. S. K. ALLISON AND A. H. ARMSTRONG. *Proc. Nat. Acad. Sci.* **11**, 563-6(1925).—The following relative intensities were found. $MoK\beta/MoK\gamma = 7.7/1$. $MoK\beta_1/MoK\beta_2 = 2/1$. $CuK\beta/CuK\gamma = 42/1$. $CuK\alpha_1/CuK\alpha_3\alpha_4 = 100/1$. In the L_γ group $\gamma_1\gamma_2\gamma_3\gamma_4\gamma_5\gamma_6\gamma_8 = 100:14.0:22.3:7.0:3.0:2.3:1(?)$. In the L_β group $\beta_1\beta_2\beta_3\beta_4\beta_5\beta_6\beta_7\beta_9\beta_{10} = 100:49.3:15.0:7.7:0.47:2.0:0.4:0.68:0.60$. The relative intensities of the lines $WL\alpha_1/WL\alpha_2$ are 10/1. S. K. ALLISON

The dispersion of potassium chloride and sodium chloride. K. F. HERZFELD AND K. L. WOLF. *Ann. Physik* **78**, 35-56(1925); cf. C. A. **19**, 1223.—As would be expected, there is a close relationship between the dispersions of the alkali halides and those of the noble gases. The dispersion depends upon the absorption frequencies of the substance, as well as upon the no. of "effective electrons" per atom. The dispersions of NaCl and KCl are given by equations of the form $(n^2-1)/(n^2-2) = \sum C_i/(\nu_i^2-\nu^2)$ where $C_i = e^2N_i p_i/3\pi m$. N_i is the no. of ions per cc; ν_i is an absorption frequency; p_i is the no. of "dispersion electrons" per ion on the classical theory, and on the quantum theory it represents a transition probability. The exptl data are represented very well by an equation contg 3 members. One member belongs to the cation, and the other two to the anion. These equations give values of p for Cl^- which are very nearly equal to those for A. The two terms in the equation which are due to Cl^- mean that there are two absorption frequencies to be attributed to it. One term contains the frequency of the center of gravity of continuous absorption, and the other, the resonance frequency. Calcn. of the continuous absorption frequency shows that the work necessary to loosen an electron from a certain chloride ion is the work done against the attraction of that ion (electron affinity) plus the work done against the attraction due to other ions at the neighboring lattice points. R. J. H.

Spectrochemistry in the infra-red. VII. The absorption of some homologous ketones. G. B. BONINO. *Gazz. chim. ital.* **55**, 335-40(1925).—In a previous paper B. (cf. C. A. **18**, 3544) showed how the mol. coeff. maxima of absorption of the band lying between 3 and 3.5 of compds. contg. H bound to C depend on the no. of H atoms in the mol. From an empirical consideration of some exptl results B. then defined the relation thus: $e_2 = e_1 + C \log_{10} (n_2/n_1)$, in which e_2 and e_1 are mol. coeff. maxima of absorption of the 2 homologous compds., C is a const. and n_1 and n_2 are the nos. of H atoms per mol. This formula holds pretty well within certain limits for monohydric alcs. and aliphatic hydrocarbons. In this paper Me_2CO , $EtCOMe$, $n-PrCOMe$ and $n-BuCOMe$ were investigated, the methods previously described (C. A. **18**, 3544) being used. For these 4 compds. the values for $e_{max.}$ were detd. to be 2.617, 3.33, 3.98 and 4.47, resp., and using $C = 6.15$ three of them were calcd. with sufficient accuracy. Using data of Coblentz (*Investig. of infr. Spectra*, Carnegie Inst. **1905**, p. 15), B. calcd. $e_{max.}$ for some satd. hydrocarbons using the above formula and $C = 46$. Aliphatic ketones show an absorption band in the infra-red presumably due to oscillators constituted of H atoms bound to C atoms. The intensity of absorption varies in the same sense as the no. of H atoms so that $e_{max.}$ can be calcd. for other terms of the series. **VIII. The absorption of some halogen-substituted hydrocarbons.** *Ibid* 341-8.—In the homologous series other characteristics of the mol. change also and the mol. coeff. of absorption may also depend on some of these in the same way that it does on the no. of H atoms. B. used $EtBr$, $C_7H_4Br_2$, $C_2H_2Cl_2$, C_2HCl_3 , C_2Cl_4 , $C_2H_2Cl_4$, C_2HCl_5 and C_2Cl_6 having the same number of C atoms but a variable no. of H atoms. In these compds. (except C_2Cl_4 and C_2Cl_6) the max. of absorption was always at 3.51μ (Langley indices). For the region of the infra-red spectrum being studied these compds. that do not contain

H do not absorb the radiation. The values of the relative coeffs. for the 2 series, but for compds. having the same no. of H atoms, are not exactly equal, which is what B. expected to find true (*l. c.*). The results indicate that variations in ϵ_{\max} at 3.5μ depend on variations in the no. of oscillators constituted of H atoms that vibrate around their position of equil. imposed by the bonds of these atoms with the C atoms of the mol. **IX. The origin of the absorption band improperly attributed to the CH_3 and CH_2 groups.** *Ibid* 576-82.—The conclusion developed in the 2 preceding abstracts is contrary to the idea of Julius (*Oefversigt of Kongl. Vetensk. Akad. Stockholm* 5, 549(1889); 5, 331(1890)), usually given by other recent workers interested in this bond, namely that it is due to CH_3 and CH_2 groups present in the mol. J.'s conclusion is a rough empirical observation. In previous papers B. (cf. *C. A.* 18, 354) has shown that the absorption band at 3.4μ in the infra-red in compds. contg. CH , CH_2 and CH_3 groups may be attributed to linear oscillators formed of H atoms that oscillate around their position of equil. His principle arguments follow (a) that hydrogenated compds. that do not contain C (e. g., H_2O , hydro acids, NH_3) show an absorption band analogous to that in question that lies nearly in the same position ($3-4\mu$) (cf. *C. A.* 18, 354); (b) that the coeff. of max. absorption of this band in various compds. follows quantitatively the variations in the no. of H atoms per mol. independently of the number of C atoms present. In the remainder of the paper, B. shows in detail how the data obtained by him cannot be readily or simply interpreted by the idea of Julius.

E. J. WITZEMANN

New lanthanum rays in the arc spectrum at normal pressure between 3100 and 2200 Å. U. PINA DE RUBIES. *Anales soc. españ. fis. quim.* 23, 444-9(1925).—The arc spectrum of the elements in the rare-earth group are not well known in the extreme ultra-violet region. R. gives 184 new La rays. The salts used were oxides of rare earths purified by methods given in *C. A.* 19, 2299.

H. M. SYMMES

Anomalous dispersion and multiplet lines in spectra. C. V. RAMAN AND S. K. DATTA. *Nature* 115, 946(1925).—Measurements of the intensities of the components of multiple spectral lines made by Dorgelo (cf. *C. A.* 19, 1376) show that the intensities are represented by a simple integral ratio. This suggests that in the case of multiplet lines, a similar numerical relationship between the consts. of anomalous dispersion might be found. A study of King's photograph (cf. *C. A.* 11, 2636; 19, 933) of the anomalous dispersion due to the Cr triplet gives dispersion consts. which are in fair agreement with the intensity ratio obtained exptly. by Dorgelo. Hence a study of King's negative is suggested.

FLORENCE N. SCHOTT

Transparency of bakelite to different radiations. JACQUES RISLER. *Compt. rend.* 181, 782-3(1925).—(1) Bakelite panels 0.5 mm. thick are transparent to ultra-violet light as follows, $\lambda = 3126$, 30%; $\lambda = 2800$, 3%; $\lambda = 2750$, 0%, the resin turning yellow. Thicker panels change color to a max. depth of 0.7 mm. corresponding to the range of the ultra-violet rays. (2) Bakelite treated with a 1-1000 soln. of safranin, and a Wratten red shield transmit red rays, resp., as follows; $\lambda = 6100$, 1.5%, 1.27%; $\lambda = 6400$, 10.5%, 10.0%; $\lambda = 6700$, 11.4%, 7.1%; $\lambda = 7000$, 15.0%, 8.0%.

P. B. PLACE

The behavior of silver iodide in the photovoltaic cell. ALLEN GARRISON. *J. Phys. Chem.* 29, 1406-7(1925); cf. *C. A.* 19, 1377.—A rejoinder to the criticism of Price (*C. A.* 19, 2167).

H. R. MOORE

An attempt to excite a mercury surface by electron bombardment. H. R. MOORE. *J. Am. Chem. Soc.* 47, 2932-3(1925).—When O_2 is suddenly admitted to a Hg surface which has been bombarded by electrons of 0-240 v. velocity, a distinct indentation or crinkling of the surface is produced. Previous studies of chem. effects produced by photoelec. emission indicate that the duration of excitation is less than a second. (Cf. Moore and Noyes, *C. A.* 18, 2288.) Since positive results were frequently obtained when the gas was admitted several min. after turning off the filament, the crinkling test is not a decisive proof of activation. The presence of an atm. of electrons would seem to guarantee the occurrence of the effect.

H. R. M.

A new aspect of the photochemical union of hydrogen and chlorine. R. G. W. NORRISH. *J. Chem. Soc.* 127, 2317-34(1925).—A new theory of the *photosynthesis of HCl* is presented, consistent with the quant. data of Coehn and Jung on the catalytic action of H_2O (*C. A.* 18, 3144). The primary reaction is dissocn. of the Cl_2 mol. rather than formation of an active modification, and occurs through intermediate formation of a loose complex of H_2O and Cl_2 on the glass surface of the reaction vessel. The reaction surface has const. catalytic properties when covered with a monomol. layer of H_2O mols.; in C. and J.'s expts. this is equiv. to a H_2O pressure of 10^{-4} mm. This theory does not dispense with the "Nernst reaction centers," which are supposed to

originate in the surface H_2O film and persist in the gaseous phase until they encounter other centers (pairs of H and Cl) or the walls of the vessel. Quant. data uphold the assumption that the induction period is due to surface poisoning and removal of H_2O from the sphere of action. The anti-catalytic action of O_2 is probably due to transference of intra-at. energy from Cl_2 on collision.

H. R. MOORE

Decomposition of ozone in red light. GEORG KISTIAKOWSKI. *Z. physik. Chem.* 117, 337-60(1925).—The photochem. transformation $2O_3 \rightarrow 3O_2$ was studied at high O_3 concns., and with a very intense 1000-watt W lamp to offset thermal decompn. With a reaction chamber of suitable dimensions, less than 3% of the total pressure increase was attributed to the dark reaction. The pressure data were checked volumetrically with NH_4I soln. Max. light absorption, detd. with a thermopile, occurred at $620 m\mu$. The quantum efficiency is a direct function of the amt. of red light absorbed and the effective pressure of O_3 in the system. On gradually diminishing the intensity of the red light with a $FeSO_4$ filter, the reaction velocity const. assumed the values 1.42, 1.33, 1.22, 1.15. With increased O_2 content, the no. of mols. transformed per $h\nu$ absorbed is 1.9, 1.25, 0.65, 0.37 for O_3 absorption percents 28.8, 21, 10.3 and 4.2, resp. O_2 exerts no inhibiting action for pressures less than 10 mm. When the total pressure of O_2 and O_3 in the system is low, the relation $dp/dt = k_2 J_{abs.}$ is valid, and 2 mols. are transformed per $h\nu$ absorbed. Inert gases, such as He, were found to catalyze the decompn., in agreement with the work of Griffith and Shutt (*C. A.* 18, 789).

H. R. MOORE

Methods for studying the chemical effects of an electric discharge in rarefied gases. PIERRE JOLIBOIS. *Compt. rend.* 181, 608-10(1925).—An app. is described in which the chem. action induced by an elec. discharge in a gas or liquid under very low pressure may be followed by observation of pressure changes. Special features are the complete isolation of the gas during reaction and the elimination of dead space. R. E. GIBSON

Microbalance. II. Photochemical decomposition of silver chloride. E. J. HARTUNG. *J. Chem. Soc.* 127, 2691-8(1925); cf. *C. A.* 16, 2266, 2623.—The photochem. decompn. of $AgCl$ in air, N and H has been investigated by means of the microbalance. The max. percentage loss of Cl in thin films of $AgCl$ when insulated was found to be: in air 91.1%, in N 89.9%, and in H 94.8%. The photochem. decompn. products are Cl and Ag; O is not necessary for the reaction. The rates of chlorination of Ag and of previously insulated $AgCl$ have been studied and it was found that optimum concns. of Cl in air exist in each case at which chlorination is most rapid and above which the rate of reaction rapidly diminishes with increasing Cl concn. No evidence of the formation of Ag subchlorides has been found.

E. P. WIGHTMAN

Light absorption and emission phenomena in anthracene. N. S. CAPPER AND J. K. MARSH. *J. Am. Chem. Soc.* 47, 2847-50(1925).—Bands found in anthracene solus. at 445 and $475 m\mu$ by Taylor and Lewis (*C. A.* 18, 2468) were not the photochemically active ones, but were due to the presence of chrysogen. Hence, the deduction that dianthracene should absorb at $707 m\mu$ does not follow, and their evidence brought forward to show that light of this wave length is capable of inducing a photochem. depolymerization of dianthracene is inconclusive. Some further information concerning chrysogen is given.

E. P. WIGHTMAN

The effect of ultra-violet light on dried hydrogen and oxygen. H. B. BAKER AND MARGARET CARLTON. *J. Chem. Soc.* 127, 1990-2(1925).—Well-dried H and O do not react when exposed for a short period to ultra-violet light. A trace of moisture, however, starts the reaction, which then increases at an increasing rate as more moisture is formed.

E. P. WIGHTMAN

Constricted mercury arc as a source of light for photochemical work. GEO. S. FORBES AND GEO. R. HARRISON. *J. Am. Chem. Soc.* 44, 2449-54(1925); cf. *C. A.* 19, 1093, 2915.—The intensity, steadiness, economy, convenience, efficiency and life of the water-cooled constricted-column Hg-vapor lamp at atm. pressure are discussed in comparison and contrast with the standard vertical-sealed-electrode com. lamp. The constricted arc will furnish, per $mm.^2$ of exit slit of a monochromator, energy flux up to 30 times that available from a com. lamp run at normal rating. For quant. work the radiations of the former must be followed by a thermopile, and the energy integrated graphically. The deterioration of this arc is more rapid than that of the com. form, being 50% for the first hr. at $\lambda = 254 m\mu$.

4- ELECTROCHEMISTRY

COLIN G. FINK

Review of the electrochemical and electrometallurgical industries for 1925. C. D. J. *four élec.* **35**, 1-4 (1926). C. G. F.

American electric furnaces for melting metals. The Detroit rocking electric furnace. H. NATHUSIUS. *Z. Ver. deut. Ing.* **69**, 1470-3 (1925).—N. discusses the practical and theoretical considerations which make elec. furnaces superior to the older types of fuel-burning furnaces. He describes the *Ajax-Wyatt* furnace as an example of the induction type. If this is to be used for melting Cu-Zn alloys showing considerable range in elec. resistance, a means of varying the primary voltage must be provided. A 30 kw. furnace produces 2-3 tons in 24 hrs. The construction of the *Detroit rocking arc type* of furnace is described together with a number of installations of this type. The thermal efficiency is 75% as against 10-15% for fuel-burning furnaces, and the energy consumption is from 330 to 360 kw. hr. per 1000 kg. of metal melted. The loss of metal is always less than 1%.

Physical-chemical rapid methods for the operating control of electric furnaces. (Ferro alloys.) I. E. SCHLUMBERGER. *Chem.-Ztg.* **49**, 913-5 (1925).—Chem. analyses are not sufficiently rapid for elec. furnace control. S. describes a rapid method for a binary mixt. of solids, alloys, etc., where the sp. gr. of the constituents is widely sepd. and where no mixed crystals are formed, which is a modification of the usual method for detg. the d. of a solid body by measuring the vol. displaced in a liquid. The weighed sample is dropped into a graduated buret in a const. temp. bath, and the vol. of the volatile liquid in the buret is measured before and after adding the sample. By use of a curve and the difference in the 2 readings, the compn. of the sample is quickly detd. The method was applied to Fe-Si, Fe-Al, Fe-W and technical CaC₂, curves being shown. Extrapolation gives the low value of 2.1 for the d. of pure calcium carbide. H. STOERTZ

Analyses of basic electric furnace steel and furnace materials in Europe. JOHN HRUSKA. *Blast Furnace & Steel Plant* **13**, 490-1 (1925).—About 100 chem. and mech. analyses, comprising practically all of importance in European elec. steel making, are given. Tabulations include: analyses of C and alloy steels, comparisons of basic elec. furnace slags, compn. of the addns., refractories, etc. A. D. S.

The Nolly electric rocking furnace. ANON. *J four élec.* **34**, 230-2 (1925); 2 illus. The roof of this furnace is a movable block of graphite. The furnace is easily opened from the top by lifting out this graphite block. When the furnace is in operation the block is luted in with fireclay into a water-cooled collar of cast iron or steel. The graphite roof is not corroded as easily as one made of refractories, by arcing or by the volatilization of lime, or by very basic slags. By proper insulation the graphite roof may be divided into several electrodes. The movable electrodes are inserted as usual at an angle through the walls of the furnace. At the bottom of the furnace is an electrode plate which is connected in parallel with a second plate on the side of the furnace so that when the charge is frozen and contact cannot be made with the plate on the bottom, then contact can be made with the plate on the side by rocking the furnace. Priming is therefore not necessary. Single- or three-phase current may be used. The furnace is suitable for melting, reductions, or refining. C. J. BROCKMAN

Electrically annealed glass superior. ANON. *Elec. World* **87**, 95 (1926).—By a uniform application of heat and a close control of temp., a continuous elec. glass annealing furnace has been perfected to yield a very satisfactory product. C. J. BROCKMAN

Automatic arc furnace (electrode) control. J. A. SEEDÉ. *Blast Furnace & Steel Plant* **13**, 482-4 (1925).—In discussing automatic electrode controls for arc furnaces melting steel and Fe, S. mentions that, owing to the excessive strains to which the mechanism of the Thury regulator was subjected, a regulator was developed which moved the electrodes from the old to the new position in one movement instead of a series of steps. The functions of the different parts of this regulator are described with the aid of figures and it is indicated that the trend for improvements is for greater simplicity and reliability. A. D. SPILLMAN

The manufacture of carborundum. IAN STEWART. *Chem. Eng. Mining Rev.* **18**, 7-9 (1925).—This is an historical review and description of the manuf. of carborundum. Furnaces in the modern installations are 50 ft. long, 80 ft. wide, and 6 ft.

high, the charge consisting of a mixt. of coke, sand, sawdust and salt. A temp. of 2250° is attained. H. STOERTZ

Note on the protection of iron by cadmium. H. S. RAWDON. *Trans. Am. Electrochem. Soc.* 49, Preprint(1926).—Simple expts. in which specimens of steel and of iron, in each of which a plug of another metal had been inserted, were immersed in dil. NaCl soln. Zn and Cd behaved *alike*. This anodic behavior with respect to Fe was also clearly revealed by the etching action which took place on the surface of the inserted plugs. Al, Ni, Cd, Cu, Sn, Pb, and Zn were used. The p. d. between Zn and Fe in contact and immersed in NaCl soln. is considerably greater than that between Cd and Fe under the same conditions. No conclusion regarding the single electrode potentials of the metals used, that is, their relative position in the series, seems warranted. W. H. BOYNTON

Studies on electroplating. VI. Barrel plating. (2) Types of plating barrels. W. E. HUGHES. *Metal Ind.* (London) 27, 379–82, 403–5, 129–30(1925); cf. C. A. 19, 3223. —H. discusses in detail the main constructional features of examples of the 2 main types of plating barrels and the advantages and disadvantages of each from the practical viewpoint. More attention toward the development of a barrel with an inside anode is needed. W. H. BOYNTON

Progress of the electroplating industry. C. H. FROCTOR. *Metal Ind.* (N. Y.) 24, 20–1(1926).—A review for 1925. E. J. C.

Plating of soda fountain fittings. JOHN YOUNG. *Metal Ind.* (N. Y.) 23, 456 (1925).—Bronze, brass, Britannia metal, nickel-silver and block Sn fittings are Ag-plated. The bath used contains 3 oz. (75 g.) Ag and 4 oz. (93.4 g.) of free cyanide per gal. Where there are deep recesses 6 oz. (170 g.) of free cyanide should be present. W. H. BOYNTON

Spotting out. R. M. GOODSSELL. *Metal Ind.* (N. Y.) 23, 457(1925); *Metal Ind.* (London) 28, 14(1926).—Spotting out from cyanide solns. is more frequently found on porous metals like cast Fe, cast bronze, and steel known as pickled stocks. The trouble is prominent in heavy plating and is minimized by keeping plenty of free CN in soln., by rinsing work thoroughly, and when using water dip lacquers, keeping the hot water used free from impurities. The lacquer should be kept cold. W. H. BOYNTON

Hydrogen-ion control of nickel-plating baths with the quinhydrone electrode. H. C. PARKER AND W. N. GREER. *Trans. Am. Electrochem. Soc.* 49, Preprint(1926).—The quality of Ni deposits depends largely upon the acidity or the p_H of the bath. The quinhydrone electrode gives reliable measurements, which must be made very rapidly when the p_H is above 8, due primarily to the oxidation of the quinhydrone in the alk soln. The set-up and diagram of connections are illusd. Curves show the effect of Ni-plating constituents on the shape of the titration curve and the change in p_H upon adding H_2SO_4 or NH_4OH to the plating solns. Colorimetric measurements are shown to have an accuracy of 0.2 p_H , while the quinhydrone electrode gives greater accuracy and is easier and quicker to manipulate, and requires less-elaborate app. W. H. BOYNTON

The production of sulfuric acid by electrolysis. ROBERT SAXON. *Chem. News* 131, 385(1925).—The addn. of Mg to a soln. of NH_4 -alum or $CuSO_4$ causes a slight evolution of H_2 which is more rapid under the influence of electrolysis. It is likewise accelerated by the addn. of an equimolar amt. of $CuSO_4$. The use of easily deposited metal assists in the production of H_2SO_4 in the electrolyte because: (1) the deposited metal juts out from the cathode, enlarging it; (2) the metal being in fine state gives a greater surface for gas discharge; (3) it forms a compd. cathode-anode between the regular electrodes everywhere where there is no actual connection with the cathode. As electrolysis proceeds alum is split, liberating NH_3 , which eventually becomes $(NH_4)_2SO_4$ and $Al(OH)_3$. The addn. of fresh $CuSO_4$ results in vigorous action which is accelerated as the Cu is deposited. Using a lighting circuit a 17% soln. of acid and an abundant crop of Cu are secured. As electrolysis removes water only, a stronger current would assist in concg. the acid by this means, and by virtue of the heat generated by passage of a greater c. d. W. H. BOYNTON

Sulfuric acid form a quadruple mixture. ROBERT SAXON. *Chem. News* 131, 372–3(1925).—Ferric ammonium sulfate on electrolysis yields $Fe(OH)_3$ and H_2SO_4 , with NH_3 and H_2 liberated at the cathode and O_2 at the anode. With the same current in series through ferrous ammonium sulfate the same evolution of gas results with that salt, when the second mixt. is $CuSO_4$ and the ferrous ammonium sulfate. In the triple mixt. the deposited Cu allows greater action resulting in a 9% H_2SO_4 in the first bath and 12% in the Cu-Fe- NH_4 mixt. When a mixt. of equiv. proportions of Ni, Cu, NH_4 and Fe⁺⁺ sulfates are electrolyzed in tandem with the same strength of ferrous ammonium

sulfate, there is only a Cu deposit with no sepn. of hydrate of Ni or Fe and the production of H_2SO_4 is more rapid than in the triple mixt. The Cu deposit is smooth and tenacious. A 7-hr. run yielded 14% H_2SO_4 in the $\text{NH}_4\text{-Fe}^{\text{m}}$ mixt. and 19% H_2SO_4 in the quadruple mixt. Where Cu is in excess the evolution of gas increases in amt. and more is dissolved and broken up

W. H. BOYNTON

Theory of the autovalue arrester. JOSEPH SELPIAN. *J. Am. Inst. Elec. Eng.* 45, 3-8(1926).—The autovalue arrester for protecting power lines from excessive voltage induced by charged clouds, etc., is of the film type. The film is a thin layer of air next to a cold cathode, which is the seat of the cathode drop by a glow discharge. With the application of sufficient voltage this air becomes ionized but the discharge of these ions into the electrodes and recombination quickly restore the normal resistivity when the voltage is reduced. A mica spacer, 0.003 to 0.005 in. thick, gives the required space regulation between the electrodes. If the electrode warms up the glow, discharge changes to an arc. This heating of the cathode is due to imperfections and an uneven c. d. over the surface of the plates. The autovalue electrodes possess a high resistivity which seems to be particularly able to prevent local overheating and therefore arcing. With 0.005 inch gap-length a break-down occurs at a little more than 350 v. The low limit for resistivity in com. autovalue electrodes is now 20 ohms per cc.; therefore the area of the electrodes det. the rate of discharge. Problems of design are discussed with the discharge curves that are given.

C. J. BROCKMAN

Electrical dust precipitation in the textile industries. O. HAHN. *Siemens Z.* 5, 604-7(1925).—High tension (50,000-80,000 v.) pptn. of dust. As the air enters the precipitator (at a speed of 40 cu. m. per sec.) it contains 30-40 mg. of dust per cu. m. The purified air contains 0.6 to 1.0 mg. dust per cu. m. Details and illus. are given.

C. G. F.

The developments in pig-iron production (HOFMANN) 9. Transformer and switch oils (ONSLow) 22.

Electric batteries. M. MARKIEWICZ and W. ROMER. *Brit.* 234,701, Oct. 31, 1924. In sealed dry cells or secondary batteries with Zn and C electrodes, a MnO_2 depolarizer and NH_4Cl in the electrolyte, MgCl_2 is added to the electrolyte and only as much H_2O is used as is normally absorbed by the electrolyte. The NH_4Cl and MgCl_2 preferably are used in equimol. proportions.

Electric batteries. W. D. FOX. *Brit.* 234,257, April 29, 1924.

Composition for coating battery terminals. C. A. SEASE. U. S. 1,569,040, Jan. 12. A coating compn. for preventing corrosion comprises NH_4 stearate 1-3 lbs., $\text{C}_{10}\text{H}_{17}$, 3 lbs., NH_3 soln. 1-3 qts. and H_2O 8-10 gals.

Storage battery. C. W. HAZELETT and A. R. GOLDRICK. U. S. 1,569,125, Jan. 12. Structural features.

Storage battery. W. H. WOOD. U. S. 1,570,115, Jan. 19. Fully charged negative plates comprise spongy Pb with MgSO_4 in its pores.

Lead oxide from old storage battery plates. S. M. EVANS. U. S. 1,570,438, Jan. 19. Pb grids and a large proportion of the sponge Pb of battery plates are sepd. from associated Pb sulfate and peroxide. The sepd. sulfate, peroxide and sponge Pb, all in finely subdivided form, are treated with a hot soln. of NaOH or other alkali metal base until an exchange of bases is effected, the treated material is washed to remove sol. salts and the residue is heated in an oxidizing furnace to produce Pb oxide.

Electrolyte-level indicator for storage batteries. H. FLEISSNER. *Brit.* 234,788, May 31, 1924. Auxiliary electrodes at the top of the battery are connected with a lamp or bell serving as a tell-tale in an external circuit.

Alkali metal amides. T. EWAN. U. S. 1,570,467, Jan. 19. An elec. current is passed between an anode of alkali metal amalgam and a cathode immersed in a soln. of an inert alkali metal salt such as NaCN in liquid anhyd. NH_3 and the reaction between the NH_3 and the metal thus removed is catalyzed, *e. g.*, by use of high-C steel for the cathode and cell walls, to produce the alkali metal amide.

Treating mercury (to obtain gold, etc.). SIEMENS & HALSKE AKT.-GES. *Brit.* 233,715, May 8, 1924. Au or other precious metal is stated to be obtained by subjecting Hg to elec. treatment; *e. g.*, an arc may be formed between Hg poles to produce Au in the Hg.

Apparatus for electric precipitation of suspended particles from gases. E. ANDERSON. U. S. 1,569,529, Jan. 12.

Apparatus for electric precipitation of suspended particles from gases. G. H. HORNE. U. S. 1,569,492, Jan. 12.

Apparatus for electric precipitation of suspended particles from gases. F. H. VIETS. U. S. 1,569,595, Jan. 12.

Apparatus for electric precipitation of suspended particles from gases. C. H. WEISKOPF. U. S. 1,569,597, Jan. 12.

Apparatus for production of electrolytic iron. E. DUHME. U. S. 1,570,212, Jan. 19. An Fe anode is used having a C content sufficient to leave a coherent graphite skeleton after the anode Fe has been electrolytically consumed.

Electric arc furnace. J. L. DIXON. U. S. 1,569,463, Jan. 12. A furnace for a. c. is specified, adapted for melting and refining metals.

Electric resistance furnace. A. D. KEENE. U. S. 1,569,376, Jan. 12.

Electric resistance furnace. J. C. WOODSON. U. S. 1,569,415, Jan. 12.

Refining steel in an electric arc furnace. J. L. DIXON. U. S. 1,569,464, Jan. 12. Currents of high and low voltages, resp., are used between different electrodes of an elec. furnace.

Electric furnace for treating gases. F. H. FROELICH. Norw. 41,983, Oct. 12, 1925. The gases are given a rapid rotary motion in a forechamber and are then passed into an extended reaction chamber through a narrow axial opening connecting the two chambers.

Electrode for electric arc furnaces. OLAF JENSEN. Norw. 42,079, Nov. 2, 1925. The electrodes are made from a mixt. or alloy contg. one or more metals which are only slightly or not at all attacked by the reaction gases and one or more metals which are difficultly atomized at the cathode.

Apparatus for electrolyzing fused metal salts. E. A. ASHCROFT. U. S. 1,569,606, Jan. 12. An app. is specified adapted for producing Mg from fused $MgCl_2$.

Electrically heated still for distilling hydrochloric acid or other materials. GRASSELLI CHEMICAL CO. Brit. 234,234, March 31, 1924.

Tungsten filaments. NAAMLooZE VENNOOTSCHAP PHILIPS' GLOEILAMPENFABRIEKEN. Brit. 234,489, May 24, 1924. Helical W filaments are subjected to a recrystn. before insertion in lamps or the like, e. g., by heating to above 1500° on a mandrel. A Mo mandrel may be removed after the heating by a mixt. of H_2SO_4 and HNO_3 or Se oxychloride, and a Ta or Zr mandrel can be removed by HF.

Sheathing for electric cables. FELTEN & GUILLEAUME CARLSWERK AKT.-GES. Brit. 233,736, May 12, 1924. Sheathing for single-core a. c. cables is made of non-magnetic Fe, e. g., Fe contg. Mn or Ni. Cr also may be added to reduce the cond. of the sheathing and thus reduce eddy currents.

Electric circuit maker and breaker electroplated with chromium. V. YNGVE. U. S. 1,570,420, Jan. 19.

Photographic transfer and electroplating process for producing ornamental embossed designs in metal. O. F. HACKER. U. S. 1,570,246, Jan. 19.

5—PHOTOGRAPHY

C. E. K. MEES

The importance of dyes in the progress of photography. A. SEYEWETZ. *Bull. soc. chim.* 37, 1197-1223(1925).—An historical and descriptive résumé of the uses of dyes in photography including the following applications: color sensitizing, desensitizing, non-halation backing for plates, prepg. dichromated gelatin images, tinting and toning of silver images and direct color formation by photochem. reactions such as the oxidation of leuco bases.

Recent progress in color cinematography. A. SEYEWETZ. *Tech. moderne* 17, 798-800(1925).—A brief review of the various processes. A. PAPINEAU-COUTURE

Photographic transfer and electroplating process for producing ornamental embossed designs in metal (U. S. pat. 1,570,246) 4.

Photographs in natural colors on paper. H. DIERNHOFER. U. S. 1,570,375, Jan. 19. Dissolved colors are transferred one after the other, from several printing plates each provided with a gelatinous layer, to a sheet provided with a receiving gelatinous layer, by placing the sheet on the printing plate, layer on layer, after protecting the color of the print already applied to the sheet against being impaired and shifting the sheet into exact register of the design with that of the plate before any color transfer is effected and then printing in the usual manner.

Nonstatic photographic film. H. J. HOFFMAN. U. S. 1,570,062, Jan. 19. A film of cellulose nitrate compn. or other cellulose ester is treated with an NH_4NO_3 soln. or other electrolyte soln. in the proportion of about 2% of the electrolyte and 98% of the solvent, such as an alc. and acetone mixt., which is a solvent also of the cellulose ester of the film. Such a quantity of this soln. is used for treating the film as will, after drying, leave, with NH_4NO_3 , about 0.25% the wt. of the film as a deposit upon the latter.

Nonstatic photographic film. E. C. PITMAN. U. S. 1,570,076, Jan. 19. Films of cellulose nitrate compns. or the like are backed with a compn. comprising NaOAc which may be used with glycerol and saponin. U. S. 1,570,077 also specifies the use of glycerol, which may be associated with NH_4OAc . U. S. 1,570,078 specifies films associated with substances for reducing surface tension, *e. g.*, saponin and glycerol, as a backing for films. U. S. 1,570,079 specifies acetate of starch in backing compus. which also may contain glycerol.

Photographic sensitive layers. KALLE & Co. AKT.-GES. Brit. 234,818, May 28, 1924. Instead of using diazo anhydrides as described in Brit. 210,862 (*C. A.* 18, 1619) sensitive layers are formed by using azo dye coupling components in conjunction with stable diazo components having the property of coupling slowly and without premature formation of the dyes. Such layers keep for a long time, especially when a non-volatile acid is incorporated with them. The exposed layer is developed with an alk. reagent such as gaseous NH_3 . Metal salts may be added and various examples are given.

Built-up multi-color photographs and cinematographic films. J. E. THORNTON. Brit. 233,989-90-1, Feb. 15 and Nov. 6, 1924. Mech. features.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Residual affinity and coördination. XXV. A quadridentate group contributing four associating units to metallic complexes. G. T. MORGAN and J. D. M. SMITH. *J. Chem. Soc.* 127, 2030-7(1925); cf. *C. A.* 20, 326.—*Diaquocobaltous ethylenediaminobisacetylacetonate*, $[(\text{H}_2\text{O})_2 \text{C}_2\text{H}_4(\text{N}:\text{C}(\text{CH}_3)\text{CH}:\text{C}(\text{CH}_3)\text{O})_2 \text{Co}]$, is prepd. from 1 mol. hexaquocobaltous chloride in 20 cc. hot water and 1 mol. $\text{C}_2\text{H}_4(\text{N}:\text{C}(\text{CH}_3)\text{CH}:\text{C}(\text{CH}_3)\text{OH})_2$ to which 2 mols. 5 *N* NaOH (8 cc.) is added. The compd. ppts. on boiling in bright orange-red prismatic needles, is insol. in H_2O and readily sol. in most org. solvents. On oxidizing this compd. by the calcd. amt. of 6 *N* H_2O_2 in the presence of excess 18 *N* NH_3 and NH_4Cl , the salt $[(\text{NH}_3)_2 \text{Co C}_2\text{H}_4(\text{N}:\text{C}(\text{CH}_3)\text{CH}:\text{C}(\text{CH}_3)\text{O})_2]\text{Cl}(\text{H}_2\text{O})_2$, *diamminoethylenediaminobisacetylacetonocobaltic chloride dihydrate* is obtained in pale fawn needles, insol. in org. solvents and moderately sol. in H_2O . It is readily transformed into *bromide*, *iodide*, *nitrite*, *nitrate*, *chlorate*, *perchlorate* and *d-camphorsulfonate*. The latter allowed in a few expts. the sepn. into a *cis-dextro* and a *cis-trans-dextro* bromide, thus revealing a racemoid mixt. They invariably transformed themselves into inactive (*trans*) bromide. The constitution is discussed.

JOHN T. STERN

Chromammynes. II. Hydroxypentamminochromic salts and electrical conductivities of chromammynes. H. J. S. KING. *J. Chem. Soc.* 127, 2100-9(1925); cf. *C. A.* 18, 2699.—A study is made on the transformation of aquo into hydroxypentamminochromic (and cobaltic) hydroxide. The elec. cond. of the aquo ion is detd. as 174.3 mhos, the cond. of the hydroxo ion to 73.3 mhos at 0°, in infinite dilution by extrapolation according to Noyes and Coolidge, giving 489.3 and 283.3 mhos for the respective hydroxides. Newly prepd. analyzed and described are: *aquopentamminochromic picrate*, $[\text{Cr}(\text{NH}_3)_5(\text{H}_2\text{O})(\text{C}_6\text{H}_2\text{O}_7\text{N}_3)_2 \cdot 1/2 \text{H}_2\text{O}]$ in yellow needles; the *oxalate*, $[\text{Cr}(\text{NH}_3)_5(\text{H}_2\text{O})_2(\text{C}_2\text{O}_4)_2 \cdot 4\text{H}_2\text{O}]$ in orange plates; the *chromic* and *cobaltic 2,4-dinitrophenoxide*, $[\text{Cr}$ or $\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})(\text{C}_6\text{H}_3\text{O}_6\text{N}_2)_3 \cdot 1$ or $3\text{H}_2\text{O}]$, in a yellow powder; and the following *hydroxypentamminochromic salts*: the *sulfate*, $[\text{Cr}(\text{NH}_3)_5\text{OH}]\text{SO}_4$, in rose-red needles; the *nitrate*, $[\text{Cr}(\text{NH}_3)_5\text{OH}](\text{NO}_3)_2 \cdot 1/2 \text{H}_2\text{O}$, in red plates; the *chloride*, $[\text{Cr}(\text{NH}_3)_5\text{OH}]\text{Cl} \cdot \text{H}_2\text{O}$, in rose needles; the *bromide* and *iodide* as pink needles with $1/2 \text{H}_2\text{O}$; the *chromate*, $[\text{Cr}(\text{NH}_3)_5\text{OH}]\text{CrO}_4$, in brown plates; and the *oxalate*, $[\text{Cr}(\text{NH}_3)_5\text{OH}]\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$, in pink needles. A table of the elec. conductivities of the various complex ions, which were studied, is given.

JOHN T. STERN

Mixed aquo-ammonocarboxylic acids. I. Ammonolysis to ammonocarboxylic acid. J. S. BLAIR. *J. Am. Chem. Soc.* 48, 87-95(1926).—A certain class of compds. of which urea, carbamic acid, biuret, etc., are examples, may be regarded as mixed aquo-ammonocarboxylic acids, which are here defined. Mixed aquo-ammonocarboxylic acids, as a

class, may be ammonolyzed to guanidine, an ammonocarbonic acid. This result is attained only in systems from which H_2O is excluded. Anhydrous liquid NH_3 solns. were used in the present investigation. The ammonolytic reaction does not go to completion but results in an equil. mixt. of guanidine, urea, and probably carbamic acid. The nature of this equil. at 300° was detd. approx. **II. Salt formation in liquid ammonia solution.** *Ibid* 96–103.—Certain of the mixed aquo-ammonocarbonic acids such as urea, biuret, guanylurea, etc., are ordinarily called bases because of their forming a base by the addition of H_2O . Their acidic character, however, has been demonstrated by the prepn., in liquid- NH_3 soln., of the following K salts of a representative no. of this class of compds. *Monopotassium carbamate*, $\text{KH}_2\text{CO}_2\text{N}$, and *dipotassium carbamate*, $\text{K}_2\text{HCO}_2\text{N}$, from the reaction of $\text{NH}_4\text{H}_2\text{CO}_2\text{N}$ with KNH_2 . The K salt of *ethyl carbamate* is unstable, the reaction between KNH_2 and the latter being, $\text{H}_2\text{N}-\text{COOC}_2\text{H}_5 + \text{KNH}_2 = \text{KNCO} + \text{C}_2\text{H}_5\text{OH} + \text{NH}_3$. *Monopotassium biuret*, $\text{KH}_4\text{C}_2\text{O}_2\text{N}_3$; *tripotassium biuret*, $\text{K}_3\text{H}_2\text{C}_2\text{O}_2\text{N}_3$; *monopotassium triuret*, $\text{KH}_4\text{C}_3\text{O}_2\text{N}_4$; *dipotassium triuret*, $\text{K}_2\text{H}_2\text{C}_3\text{O}_2\text{N}_4$; and *monopotassium ethyl allophanate*, $\text{KNHCON}-\text{HCOOC}_2\text{H}_5$; each from the reaction of KNH_2 with the corresponding aquo-ammonocarbonic acid. Monopotassium ethyl allophanate decomposes at 215° giving KNCO and ethyl carbamate. The action of excess KNH_2 on ethyl allophanate eliminates the (C_2H_5) , presumably by ammonolysis, and forms cyanates; but the reaction requires further study.

R. H. LOMBARD

The group of volatile hydrides. Supplementary remarks. FRITZ PANETH AND EUGEN RABINOWITSCH. *Ber.* 58B, 2446–8(1925).—Polemical against Hantzsch and Carlsohn (*C. A.* 20, 130). As a supplement to their previous paper (*C. A.* 19, 2460). P. and R. give as a new law: The b. p. of a halide of a metal of the Si group is equal to the sum of the b. p. of the halogen plus the b. p. of the rare gas at the beginning of the period following that in which the metal occurs.

EMIL KLARMANN

The formula of cerium hydride. E. J. WEEKS. *Chem. News* 131, 245–6(1925).—Muthmann and Kraft (*Ann.* 325, 261(1902)) ascribed a formula to Ce hydride on the basis of 2.4% H in their sample. CeH_3 requires 2.09% and CeH_4 , 2.79% CeH_3 was chosen because cerous salts were formed with acids. This and the fact that CeH_2 forms CeO_2 and CeN with O_2 and N_2 , resp., may be explained by the theory that Ce hydride consists of a mixt. of CeH_4 and Ce_2H_2 , the latter dissociating to form CeH_4 and Ce, which would unite with O or N. At higher temps. CeH_4 would decompose into Ce and H_2 . W.'s theory of mixed hydrides is substantiated by the fact that Muthman and Baur (*Ann.* 325, 281(1902)) found that the dissociation pressure of the hydride was not constant.

M. O. LAMAR

Compounds of some bivalent, trivalent and quadrivalent metals with pyrocatechol. R. WEINLAND AND HELENE SPERL. *Z. anorg. allgem. Chem.* 150, 69–83(1925).—It is known that pyrocatechol forms complex compds. with many metals. The authors prepd. the following new compds: *sodium tripyrocatecholatomanganate*, $[\text{Mn}(\text{C}_6\text{H}_4\text{O}_2)_3]\text{Na}_3 \cdot 1/2\text{NaOH} \cdot 6\text{H}_2\text{O}$; *potassium tripyrocatecholatomanganate*, $[\text{Mn}(\text{C}_6\text{H}_4\text{O}_2)_3]\text{K}_3 \cdot 3\text{H}_2\text{O}$; *ammonium tripyrocatecholatomanganate*, $[\text{Mn}(\text{C}_6\text{H}_4\text{O}_2)_3](\text{NH}_4)_2 \cdot 5\text{H}_2\text{O}$; *basic manganese pyrocatecholate*, $\text{Mn}_6(\text{OH})_2(\text{C}_6\text{H}_4\text{O}_2)_8 \cdot 10\text{H}_2\text{O}$; *pyridine dipyrocatecholatomanganate*, $4[\text{Mn}(\text{C}_6\text{H}_4\text{O}_2)_2] \cdot \text{H}_2\text{py}_2 \cdot \text{C}_6\text{H}_4(\text{OH})_2$; *pyridine dipyrocatecholatomnickelate*, $4[\text{Ni}(\text{C}_6\text{H}_4\text{O}_2)_2] \cdot \text{H}_2\text{py}_2 \cdot \text{C}_6\text{H}_4(\text{OH})_2$; *pyridine dipyrocatecholatozincate*, $[\text{Zn}(\text{C}_6\text{H}_4\text{O}_2)_2] \cdot \text{H}_2\text{py}_2$; *pyridine chloropyrocatecholatosilicate*, $[\text{Sn}(\text{C}_6\text{H}_4\text{O}_2)_2]\text{Cl} \cdot \text{Hpy}$; *a pyridine pyrocatecholaluminum compd.*, $[\text{Th}(\text{OC}_6\text{H}_4\text{O})_4] \cdot \text{H}_4\text{py}$; *a pyridine pyrocatecholozirconium compd.*, $2[\text{Zr}(\text{C}_6\text{H}_4\text{O}_2)_3] \cdot \text{H}_2\text{py}$; *a pyridine pyrocatecholatoaluminum compd.*, $[\text{Al}(\text{C}_6\text{H}_4\text{O}_2)_2] \cdot \text{Hpy} \cdot \text{H}_2\text{O}$; *a bismuth pyrocatechol compd.*, $\text{C}_6\text{H}_4\text{O}_2\text{BiOC}_6\text{H}_4\text{OH}$; and *a bismuth nitrate pyrocatechol compd.*, $\text{Bi}(\text{OC}_6\text{H}_4\text{OH})_2\text{NO}_3$.

EMIL KLARMANN

Dichromates of ter- and sexivalent metals. G. CALCAGNI. *Gazz. chim. ital.* 55, 396–406(1925).—The basis of this work was the idea that in heating CrO_3 to redness Cr chromate is formed. The various oxides of Cr of interest in this connection are reviewed, but are largely rather indefinite compds. The metallic oxides and hydroxides were dissolved in CrO_3 . Numerous other ways of prepg. these compds. were tried. The products obtained were black, amorphous and hygroscopic. They decompd. above $130\text{--}40^\circ$ but most of them were analyzed in the moist condition with a correction for the H_2O present. Excess $\text{Cr}(\text{OH})_3$ was placed in CrO_3 soln. The liquid became brown and on evapn. of the clear soln. a pasty amorphous mass was obtained. This was dried in an oven below 130° and was hygroscopic and easily sol. in H_2O ; at temps. above 130° it is decompd., giving products difficultly sol. in H_2O and even in boiling HCl . When Cr_2O_3 was allowed to act in CrO_3 soln. at low temps. for some days the solns. on evapn. gave *chromium dichromate*, $\text{Cr}_2(\text{Cr}_2\text{O}_7)_3$. The product obtained with $\text{Cr}(\text{OH})_3$ was the *basic dichromate* $\text{O}(\text{Cr}:\text{Cr}_2\text{O}_7)_2$, if thoroughly dry and insol. in H_2O ,

or $\text{Cr}(\text{OH})\text{Cr}_2\text{O}_7$ if it had not been dried above 130° . $\text{Fe}(\text{OH})_3$ in CrO_3 soln. treated as above at low temps. and then finally evapd. and dried at 140° gave the *basic dichromate of iron*, $\text{O}(\text{Fe}:\text{Cr}_2\text{O}_7)_2$; the compd. $\text{Fe}(\text{OH})\text{Cr}_2\text{O}_7$ was not isolated from soln. in this case. In the same way, the *basic dichromate of aluminium* was isolated. Solns. of MoO_3 and CrO_3 were repeatedly evapd. The product formed was *molybdenum dichromate*, $\text{Mo}(\text{Cr}_2\text{O}_7)_3$. Attempts to obtain the corresponding W compd. failed. U_3O_8 is sol. in solns. of CrO_3 . The compn. of the product obtained does not resemble that of the other compds. described above.

H. J. WITZEMANN

The separation of the platinum metals. LOTHAR WÖHLER AND L. METZ. *Z. anorg. allgem. Chem.* **149**, 297-323(1925).—For most of the chem., phys. and electro-technical uses to which they are put, the metals of the Pt group should be in as pure a state as possible; hence the importance of improved methods of sepn. In a detailed study, W. and M. find that: (1) In the presence of Te or Pb, Os volatilizes as the tetroxide when distd. with acid permanganate or chromosulfuric acid, but not in the presence of Ru. (2) In the presence of Te, Ru and sulfides, Os may be volatilized in the presence of the nitrogen oxides (preferably NO_2) and a much better sepn. obtained at 275° than by volatilization in air. A satisfactory sepn. of Os in the presence of nitrate and nitrite is shown to be possible. (3) OsO_2 , formerly considered difficult to prep., results from the action of NO on Os at 520° . (4) In NO_2 at 275° Te slowly forms TeO_2 ; above 370° this decomposes into Te and TeO_2 . (5) Rh is sepd. from Ru or Ir by fusing it with more than 20 times its wt. of Bi and dissolving the melt in HNO_3 . If 10 instead of 20 parts of Bi are used, a *new cryst. alloy*, RhBi_2 , results, which is insol. in HNO_3 , though sol. in aqua regia. (6) Rh may be sepd. from Ir by transformation into the anhyd. complexes Na_3RhCl_6 or Na_2IrCl_6 . The complex of quadrivalent Ir is easily sol. in cold 1:1 acetone-ether, while that of trivalent Rh is entirely insol. (7) Molten NaOH at 550° converts Ru mostly to the sol. ruthenate, the small residue of RuO_2 being sol. in HNO_3 . Ir is not dissolved by molten NaOH (though appreciably dissolved by KOH) but is oxidized to IrO_2 insol. in HNO_3 . This furnishes a sepn. of Ru from Ir and Rh. Molten K_2CO_3 dissolves Ir, in consequence of higher temp., more than KOH while molten Na_2CO_3 dissolves only a little Ru, more, however, than does NaOH. (8) Finely divided metallic Ru (not in an alloy with Ir or Rh) can be converted directly by distn. with alkali chlorine compds., as NaClO , into the volatile tetroxide. Thus the oxidation with K_2CO_3 and KNO_3 or Na_2O_2 is avoided. But to sep. Ru from an alloy with Ir the sol. ruthenate first must be formed by oxidizing fusion. (9) By following the above methods it has been possible to obtain a satisfactory analysis of a complicated mixt. of the Pt metals. Recommended analytical procedure: (1) volatilize Os by NO_2 ; (2) extract Pt and Pd by dil. aqua regia and ppt. Pt with concd. NH_4Cl soln.; (3) fuse the insol. residue from (2) with Bi to dissolve Rh; (4) in the insol. residue separate Ru from Ir by alk. Cl_2 distn. or fusion with NaOH. Or, (3) volatilize Ru, then separate Rh from Ir by fusion with Bi. The analysis is detailed of a complicated mixture containing Os, Ru, Pt, Rh, Ag, Sb, Te, Fe, Al, SiO_2 , S, etc.

ROSALIE M. COBB

The binary bromides and iodides of platinum. LOTHAR WÖHLER AND F. MÜLLER. *Z. anorg. allgem. Chem.* **149**, 377-86(1925).—It is possible to obtain PtBr_4 by direct combination, but the yields are poor. For the prepn. of the Pt halogens, Br_2 or I_2 is heated to boiling in a retort and led at atm. pressure into a Jena glass reaction chamber, which contains Pt or a Pt compd. Const. temp. is maintained by a 1 mm. Ni or chrome-nickel coil, and the temp. recorded by a Ag-Ni thermoelement. Uncombined I_2 and Br_2 are drawn off and condensed. PtBr_4 is obtained by passing Br_2 over H_2PtBr_6 at $285\text{--}310^\circ$, while at 335° a new compd., *platinum tribromide*, PtBr_3 , results. PtBr_3 is perfectly stable at 368° , but at 410° loses 1.6% Br in 16 hrs. It is difficultly sol. in cold water, more easily in hot; its soln. is acid, on account of the probable formation of the complex $\text{H}_2\text{PtBr}_3(\text{OH})_2$. Its greenish black crystals dissolve slowly in alc. and acetic ester; complexes are formed with HBr and the alk. bromides. In all these properties its behavior is half-way between that of PtBr_4 and PtBr_2 . PtI_3 , *platinum triiodide*, may be obtained by heating PtI_4 in a current of I_2 to $262\text{--}272^\circ$, or by passing I_2 over Pt black for 4 days at 350° . Excess I_2 is removed by a CO_2 stream at $80\text{--}90^\circ$. *Platinum tetra, tri and bi iodides* are all black, insol. in water, ether and acetic ester; PtI_4 is slightly sol. in alc. They form dark reddish brown complexes with I and KI. The dissociation of PtI_4 and PtI_3 seems to be autocatalytic, and the temp. between them is so small as to make it difficult to det. the rate of dissociation. PtI_3 can be obtained only above 411° or at 3 atm. and 350° . A phase diagram is given for the Pt halides and Ir chlorides.

ROSALIE M. COBB

Lead bromate and diaceto-diplumbic bromate. E. GÜNZEL AND E. MARCUS.

Z. angew. Chem. **38**, 929–30 (1925).—One of the methods given in Gmelin-Kraut for the prepn. of $\text{Pb}(\text{BrO}_3)_2 \cdot \text{H}_2\text{O}$ is by the action of an alkali bromate upon excess $\text{Pb}(\text{AcO})_2$ in the presence of AcOH . This method led to a fatal accidental explosion. Weinland and Paul (cf. *C. A.* **17**, 3293) have prepd. an explosive diaceto-diplumbic bromate. This compd. is sometimes formed if Gmelin-Kraut's method is used for the prepn. of $\text{Pb}(\text{BrO}_3)_2 \cdot \text{H}_2\text{O}$. The formation is not limited to W. and P.'s particular conditions but may take place when one would expect to have only the bromate produced. G. and M. warn against the use of this method.

M. O. LAMAR

The equilibrium in the systems aluminium sulfate-copper sulfate-water and aluminium sulfate-ferrous sulfate-water at 25° . V. J. OCCLESIAW. *J. Chem. Soc.* **127**, 2598–602 (1925); cf. Caven and Mitchell, *C. A.* **19**, 3440.—The triple component diagrams for $\text{Al}_2(\text{SO}_4)_3$, CuSO_4 , H_2O and $\text{Al}_2(\text{SO}_4)_3$, FeSO_4 , H_2O are given for a temp. of 25° . There is no double salt formation in the CuSO_4 system. In the FeSO_4 system, a salt $\text{Al}_2(\text{SO}_4)_3 \cdot \text{FeSO}_4 \cdot 24\text{H}_2\text{O}$ exists at 25° and O. succeeded in crystg. it from an aq. soln. of equi-mol. quantities of $\text{Al}_2(\text{SO}_4)_3$ and FeSO_4 .

D. S. VILLARS

The fluoro salts of aluminium, trivalent iron and chromium. R. WEINLAND, IRMA LANG AND HEINRICH FIKENTSCHER. *Z. anorg. allgem. Chem.* **150**, 47–67 (1925).—The purpose of this paper is to establish whether the above named metals possess a varying coordination number in fluoro anions. The cations were hydrazine, pyridine, ethylenediamine and guanidine. Thus in the fluoaluminates the Al has the coordination number 6, all compds. permitting a derivation from the type of the hexafluoro- or pentafluoaqualuminate ion. In the series of fluoferrates, when guanidine or ethylenediamine was used, the formation of only the pentafluoaquoferrate ion was observed (coordination number 6) while pink tetrafluoro- and greenish pentafluoaquo compds. (coordination number 4 and 6, resp.) are formed with pyridine. The coordination number of Fe in the K and NH_4 fluoferrates is 4, while in the corresponding Ag, Tl, Cd and Cu compds. it is 6, a pentafluoaquo ion being formed with the first three as cations and a hexafluoferrate ion with the latter. The trivalent Cr shows the coordination number of 6, all known compds. allowing a derivation either from the hexafluoro- or the pentafluoaquo anion. In some cases a binuclear formulation is necessary in order to visualize the coordination number of 6, e. g., $2(\text{FeF}_3 \cdot$

$2\text{NH}_4\text{F}) = \left[\text{F}_4\text{Fe} \begin{array}{c} \nearrow \text{F} \\ \searrow \text{F} \end{array} \text{FeF}_4 \right] (\text{NH}_4)_4$. It is possible, but improbable, that there are

compds. with the coordination number of 5. The prepn. of the following compds. is described. *Hydrazinefluoaaluminate*, $[\text{AlF}_6]\text{H}_2\text{N}_2\text{NH}_2$, *pyridine fluoaaluminate*, $[\text{AlF}_6]\text{H}_2 \cdot 2\text{C}_5\text{H}_5\text{N} \cdot \text{H}_2\text{O}$; *ethylenediaminefluoaaluminate*, $[\text{AlF}_6]\text{H}_2 \cdot \text{C}_2\text{H}_4(\text{NH}_2)_2 \cdot \text{H}_2\text{O}$; *guanidine tetrafluoaaluminate*, $[\text{AlF}_6]\text{H} \cdot \text{CN}_2\text{H}_5 \cdot \frac{1}{2}\text{H}_2\text{O}$; *guanidine pentafluoaaluminate*, $[\text{AlF}_6]\text{H}_2 \cdot (\text{CN}_2\text{H}_5)_2$; *guanidine hexafluoaaluminate*, $[\text{AlF}_6]\text{H}_3 \cdot (\text{CN}_2\text{H}_5)_3$; *potassium pentafluoaaluminate*, $[\text{AlF}_6]\text{K}_2 \cdot 2\text{H}_2\text{O}$; *guanidine pentafluoaquoferrate*, $[\text{FeF}_6(\text{H}_2\text{O})]\text{H}_2 \cdot (\text{CN}_2\text{H}_5)_2$; *ethylenediaminepentafluoaquoferrate*, $[\text{FeF}_6(\text{H}_2\text{O})]\text{H}_2 \cdot \text{C}_2\text{H}_4(\text{NH}_2)_2$; *pyridine pentafluoaquoferrate*, $[\text{FeF}_6(\text{H}_2\text{O})]\text{H}_2 \cdot (\text{C}_5\text{H}_5\text{N})_2 \cdot 2\text{H}_2\text{O}$; *pyridine tetrafluoferrate*, $[\text{FeF}_4] \cdot \text{H} \cdot \text{C}_5\text{H}_5\text{N} \cdot \text{H}_2\text{O}$; *potassium tetrafluoferrate*, $[\text{FeF}_4]\text{K}$; *ammonium tetrafluoferrate*, $[\text{FeF}_4] \cdot \text{NH}_4$; *silver pentafluoaquoferrate*, $[\text{FeF}_6(\text{H}_2\text{O})]\text{Ag}_2 \cdot 2\text{H}_2\text{O}$; *thallium pentafluoaquoferrate*, $[\text{FeF}_6(\text{H}_2\text{O})]\text{Tl}_2 \cdot 2\text{H}_2\text{O}$; *hexafluocadmium pentafluoaquoferrate*, $[\text{FeF}_6(\text{H}_2\text{O})] \cdot [\text{Cd}(\text{H}_2\text{O})_6]$; *hexafluocopper hexafluoferrate*, $[\text{FeF}_6]_2[\text{Cu}(\text{H}_2\text{O})_6]_3$; *guanidine hexafluochromate*, $[\text{CrF}_6]\text{H}_3 \cdot 3\text{CN}_2\text{H}_5$. The ferric fluoride 4.5 hydrate does not contain any bivalent Fe, contrary to a statement made by Deussen and Kessler (*C. A.* **1**, 1527). Its tentative formula is $\text{FeF}_3 \cdot 4.5\text{H}_2\text{O} = [\text{FeF}_6(\text{H}_2\text{O})_3] \cdot 1.5\text{H}_2\text{O}$. EMIL KLARMANN

Decomposition of alkaline earth phosphates by means of alkali carbonates. D. RAQUET. *Bull. soc. chim.* **37**, 1548–9 (1925); cf. Colani, *C. A.* **19**, 3230.—Treatment of alk.-earth phosphates with alkali carbonates showed the following % of phosphate decomposed:

Reagent	NH_4MgPO_4	$\text{Ca}_3(\text{PO}_4)_2$	$\text{Sr}_3(\text{PO}_4)_2$	$\text{Ba}_3(\text{PO}_4)_2$
Satd. Na_2CO_3	40	30	90	95
Satd. $\text{Na}_2\text{CO}_3 + \text{NaOH}$	94.5	25	85	90
Concd. K_2CO_3 (1:1)	5	50	100	100
Concd. K_2CO_3 (1:1) + NaOH	94.5	35	95	95

NaOH interferes slightly with the decompn. of the Ca, Ba and Sr phosphates, but is necessary for the decompn. of the Mg salt. R. considers that decompn. of the alk.-earth phosphates with concd. alkali carbonate soln. is quite sufficient for use in qual. analysis.

A. PAPINEAU-COUTURE

The acetato (formato) cations of cadmium, manganese, lead and the alkaline earths.

R. WEINLAND AND HERMANN SCHLAICH. *Z. anorg. allgem. Chem.* **150**, 35-46(1925); cf. *C. A.* **17**, 3293.—A series of new compds. of Cd and Mn was prepd. which show a behavior similar to that of Pb and the alkaline earth compds. previously described. Besides, some new compds. with *p*-nitrophenol were prepd. The same method of prepn. was used in all cases, a soln. of the metal acetate or formate of HClO_4 , HNO_3 , picric acid or *p*-nitrophenol, resp., having been allowed to evap. slowly; in some instances the presence of AcOH was required. Thus the following compds. were obtained
acetatocadmium picrate, $[\text{Cd}_2(\text{AcO})_2]\text{picr}_2 \cdot 3\text{H}_2\text{O}$; *acetatocadmium p-nitrophenolate*, $[\text{Cd}_2(\text{AcO})_2](\text{OC}_6\text{H}_4\text{NO}_2)_2 \cdot 2\text{C}_6\text{H}_4(\text{NO}_2)\text{OH} \cdot \text{AcOH} \cdot 6\text{H}_2\text{O}$; *acetatodicadmium perchlorate acetate*, $[\text{Cd}_2(\text{AcO})_2](\text{AcO})\text{ClO}_4 \cdot 3\text{H}_2\text{O}$; *acetatocadmium nitrate*, $[\text{Cd}_2(\text{AcO})_2](\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$; *acetatocadmium perchlorate*, $[\text{Cd}_3(\text{AcO})_4](\text{ClO}_4)_2 \cdot 2\text{H}_2\text{O}$; *formatocadmium picrate*, $[\text{Cd}_2(\text{OOCH})_2]\text{picr}_2 \cdot 6\text{H}_2\text{O}$; *acetatomanganese picrate*, $[\text{Mn}_2(\text{AcO})_2]\text{picr}_2$; *acetatomanganese p-nitrophenolate*, $[\text{Mn}_3(\text{AcO})_4](\text{OC}_6\text{H}_4\text{NO}_2)_2 \cdot \text{AcOH} \cdot 9\text{H}_2\text{O}$; *acetatolead p-nitrophenolate*, $[\text{Pb}_2(\text{AcO})_2](\text{OC}_6\text{H}_4\text{NO}_2)_2 \cdot 2\text{AcOH}$; *acetatobarium p-nitrophenolate*, $[\text{Ba}_2(\text{AcO})_2](\text{OC}_6\text{H}_4\text{NO}_2)_2 \cdot 2\text{AcOH} \cdot 6\text{H}_2\text{O}$; *acetatocalcium p-nitrophenolate*, $[\text{Ca}_2(\text{AcO})_2](\text{OC}_6\text{H}_4\text{NO}_2)_2 \cdot 2\text{AcOH} \cdot 4\text{H}_2\text{O}$; and *acetatostrontium p-nitrophenolate*, $[\text{Sr}_2(\text{AcO})_2](\text{OC}_6\text{H}_4\text{NO}_2)_2 \cdot 2\text{AcOH} \cdot 6\text{H}_2\text{O}$. The compds. with *p*-nitrophenol probably possess a configuration similar to that of the aquo compds. *i. e.*, the connection is established by the O of the OH group of the phenol (cf. *C. A.* **13**, 1714); on the other hand the NO_2 group possibly might effect the attachment.

EMIL KLARMANN

The desulfurization of heavy metal sulfides with barium oxide. WILHELM BILTZ AND ERNST VON MÜLLENDAIL. *Z. anorg. allgem. Chem.* **150**, 1-9(1926).—The reactions between Cu_2S , CuS , PbS and BaO were studied microscopically, chemically and thermodynamically. They proceed according to the equations: $\text{M}'\text{S} + \text{M}''\text{O} = \text{M}'\text{O} + \text{M}''\text{S} + \text{Q}$, $4\text{M}'\text{O} + \text{M}''\text{S} = 4\text{M}' + \text{M}''\text{SO}_4 + \text{Q}$, and combining these $4\text{M}'\text{S} + 4\text{M}''\text{O} = 4\text{M}' + 3\text{M}''\text{S} + \text{M}''\text{SO}_4 + \text{Q}$, in which M' is a bivalent heavy metal or 2 atoms of a univalent heavy metal and M'' is an alk. earth atom. The reactions take place in the absence of C and with exclusion of air and commence between 200° and 400° . The greatest yield of heavy metal was obtained when 2 moles of BaO per mole of sulfide were used and the reaction time was 1 hr. With Cu_2S and BaO , the yield was 50-60% of the theoretical under these conditions. With Cu , the sulfide is completely decompd. at 800° , but Cu_2O remains, while with PbS the sulfide is never completely decompd. It was not possible to substitute CaO for BaO . Tables and time-temp. curves are included.

H. STOERTZ

Sulfur monochloride and sulfur. G. BRUNI. *Z. anorg. allgem. Chem.* **149**, 387-8 (1925); cf. *C. A.* **14**, 2893.—The conclusion drawn by Ruff and Golla (*C. A.* **19**, 221), that S is dissolved in S_2Cl_2 as S_8 , has been previously published by B. R. M. C.

Hypochlorous acid and the alkali hypochlorites. GEORG MÜLLER. *Z. anorg. allgem. Chem.* **149**, 401-2(1925); cf. *C. A.* **19**, 3441.—The observation of Dietzel and Schlemmer, that the reaction $2\text{NaOH} + \text{Cl}_2 = \text{NaOCl} + \text{NaCl} + \text{H}_2\text{O}$ does not go quant. as indicated, is due to confusion between equiv. and mol. wts. Where 2 mols. of NaOH is required, they seem to have used but 1; hence the apparent deficiency of titratable NaOCl .

ROSALIE M. COBB

The reaction between bismuth trisulfide and hydrochloric acid. S. RAMACHANDRAN. *Chem. News* **131**, 294-5, 386(1925).— HCl of all concns. up to 1:16 aq. acts upon Bi_2S_3 with liberation of H_2S . Bi_2S_3 dissolves easily in boiling HCl of 1:5 aq. concn. The more dil. the acid, the higher the temp. at which H_2S is evolved. With 1:5 aq. acid the H_2S begins to be evolved at 40° ; with 1:16 aq. acid at 70° . Even at 29° there is soln. of Bi_2S_3 . Mere diln. of the acid solns. does not ppt. the Bi_2S_3 . Keeping Bi_2S_3 in contact for 48 hrs. with the soln. from which it is pptd. apparently does not change its properties.

M. O. LAMAR

Reactions of the type $\text{Cl}_2 + 2\text{KOH} = \text{KCl} + \text{KClO} + \text{H}_2\text{O}$. F. W. BERGSTROM. *J. Phys. Chem.* **30**, 12-9(1926).— KNH_2 reacts in liquid NH_3 with Pb and all elements more electronegative than Pb, provided the alkali metal salts contg. these elements in homo-at. anions are sol. in liquid NH_3 . These reactions are all of the type named in the title. The reactions in aq. solns. of bases and Sn, As or P are also of this type. The H_2 , AsH_3 , or PH_3 obtained in these cases results from hydrolysis of the potassium stannide, arsenide or phosphide, resp., produced. K and Na ammonostannites ($\text{K}[\text{Sn}(\text{NH}_2)_2]$, etc.) were prepd. They are white solids, very reactive with water and derivs. of bivalent Sn.

D. S. VILLARS

A new peroxide of barium. MARGARET CARLTON. *J. Chem. Soc.* **127**, 2180-4 (1925).—If instead of adding just enough H_2O_2 to aq. $\text{Ba}(\text{OH})_2$ at 15° to form $\text{BaO}_2 \cdot 8\text{H}_2\text{O}$, excess H_2O_2 is added, a granular ppt. is formed. This becomes buff-colored on standing and on being dried over P_2O_5 in *vacuo* it becomes first deeper buff, then lighter,

finally giving a cream colored amorphous powder (cf. Schöne, *Ann.* **192**, 257(1898)). Analysis indicated it to be the previously unknown *compd.*, BaO_3 . It decolorizes neutral $KMnO_4$ faster than does BaO_2 . It does not liberate I from neutral KI even on standing but in the presence of HNO_3 I is rapidly liberated in greater quantity than from BaO_2 . It does not react with neutral KBr , but on adding a trace of HNO_3 or HF , Br is liberated, whereas only a trace is liberated with BaO_2 . Unlike BaO_2 , Cl is liberated from concd. HCl and when heated with S no SO_2 is liberated, though there is vigorous action in the latter case. The reactions in general show BaO_3 to be a very active oxidizing agent, much more so than BaO_2 . Expts. are to be continued to prep. from this a new peroxide of H.

C. C. DAVIS

Purification of phosphoric oxide. HENRY WHITAKER. *J. Chem. Soc.* **127**, 2219–21(1925).—The difficulties inherent in the method of Finch and Peto (*C. A.* **16**, 2277) for purifying P_2O_5 are overcome by using a special new type of receiver which is described and illustrated. $HgCl_2$ is more convenient than $AgNO_3$ as a reagent for detecting the presence of lower oxides of P, since with $HgCl_2$ the H_3PO_4 need not be neutralized with $NaOH$. A turbidity or ppt. of $HgCl$ on boiling P_2O_5 with aq. $HgCl_2$ indicates the presence of P_2O_3 in the P_2O_5 .

C. C. DAVIS

Compounds and alloys of titanium with aluminum. W. MANCHOT and A. LEBER. *Z. anorg. allgem. Chem.* **150**, 26–34(1926).—Al is melted in a crucible and K_2TiF_6 is added in small portions. A Ti content of more than 37.3% caused the formation of a non-homogeneous mass contg. undecomposed Ti salts and metal. The hardness of the melt increased with increasing Ti content; it becomes very hard with more than 20% Ti. Dctn. of the cooling curve shows 2 branches, one characterized by a temp. max. of 1355°, corresponding to a Ti content of 37.28% by wt and 25 at. %. Since this point represents 3 parts of Al to 1 of Ti, the compd. Al_3Ti must sep. along this branch. The other branch corresponds to a temp. of 658°, along which Al crystallizes out. There is no indication of mixed crystals of Al and Al_3Ti . Photomicrographs are shown for Ti content of 1.5, 3.0, 11.2, 26.2, 36.0 and 37.3%, needle-like crystals of Al_3Ti being plainly seen. Small bright crystals of nitride are present as an impurity. Al_3Ti can be isolated by action of 5% HCl on the alloy, but if Ti is high it is better to use 5% $NaOH$ to dissolve out Al and wash with H_2O and alc. The compd. has a d. of 2.74. For analysis it is dissolved in concd. HCl and Ti titrated with *methylene blue*. Another sample is decomposed in concd. HNO_3 , the residue after evapn. ignited and weighed as the mixed oxides of Al and Ti. These are then fused in Na_2CO_3 and K_2CO_3 , the melt is dissolved in HCl , neutralized with NH_4OH and TiO_2 pptd. with SO_2 . Al is detd. in the filtrate by pptn. with NH_4OH . The results agree with the formula Al_3Ti . The authors were unable to obtain any other compd. of Al and Ti, and repeated efforts failed to introduce more than 37.3% Ti into the alloy. This is not in agreement with the work of other investigators.

H. STOERTZ

Hydroxides of Al and of Fe (HABER) 2. Supposed isomorphism of compounds of uranyl with those of the isomorphogenic metals of the Mg group (CAROBBI) 2. X-ray investigation: of Pd-Ag alloys containing H (KRÜGER, SACKLOWSKI) 2.

7—ANALYTICAL CHEMISTRY

WILLIAM T. HALL

Points arising from the analytical standardization of British chemical standards. C. H. RIDSDALE and N. D. RIDSDALE. *Analyst* **50**, 425–40(1925).—Just as the U. S. Bureau of Standards has had various materials sampled and analyzed until the chem. compn. is established with considerable certainty to serve as standards, so in England similar materials have been analyzed and offered to chemists for the purpose of testing their methods of analysis. The evidence shows indisputably that errors are likely to arise in the work of any chemist, no matter how skilful, and that the mere checking of one's results does not prove that the method is accurate. A strong plea is made for the "mechanicalizing" and standardizing of methods of procedure and for common sense among chemists in reporting their results. One should not say that a sample contains 81.850% Fe_2O_3 when about 81.5% is present.

W. T. H.

Investigation into the analytical chemistry of tantalum, columbium and their mineral associates. IV. A new method for the separation of tantalum from columbium. V. The detection and determination of tantalum in columbium compounds. A. R. POWELL and W. R. SCHORLLER. *Analyst* **50**, 485–98(1925).—To sep. Ta from Cb advantage can be taken of the different extents to which oxalotantalic and oxalocolumbic

acids are affected by hydrolysis. The former complex acid is stable only in the presence of oxalic acid but the latter is relatively stable. Tannin favors the hydrolysis of the Ta compd. and the ppt. formed on boiling the slightly acid soln. is probably an adsorption product of tannin and tannic acid. The method is subject to 2 errors: (1) contamination of the ppt. by adsorption and (2) the danger of getting incipient pptn. of Cb because of the narrow range between complete pptn. of Ta and partial pptn. of Cb. When the ignited Ta ppt. is orange or red, the sepn. should be repeated. Fuse 0.3-0.5 g. of the mixed oxides with 3-6 g. of $K_2S_2O_7$. If the melt does not become clear, cool, add 1 cc. of concd. H_2SO_4 and again heat. Leach the cold melt with a satd. soln. of 2-4 g. $(NH_4)_2C_2O_4$ and filter if necessary. Fuse the residue again in the same SiO_2 crucible. Dil. the soln. to a vol. of about 125 cc. for each 0.1 g. of original oxide and add 10 cc. of freshly prepd. 2% tannin soln. If no permanent turbidity results after a short boiling period, add 0.5 *N* NH_4OH to the vigorously stirred soln. until a permanent ppt. forms. Now add more tannin if necessary (0.2 g. for less than 0.03 g. Ta_2O_5 ; 1 g. for 0.25 g. Ta_2O_5). Next add 5 g. NH_4Cl dissolved in as little water as possible. If the ppt. is orange to red, the soln., though sometimes of a pale straw tint, should be free from any orange color or cloudiness. If not, continue boiling and add more NH_4OH as necessary. Filter and wash with 2% NH_4Cl soln. If the filtrate is not practically colorless, again boil, add 5-10 cc. of tannin soln. and NH_4OH enough to decolorize any colloidal soln. Filter, ignite and again fuse with $K_2S_2O_7$, this time using oxalate as described below. If the first ppt. is S-yellow, filter and wash as above. Evap. the filtrate to $\frac{3}{4}$ of its original vol., add a little tannin, boil, and add NH_4OH dropwise until the orange coloration that forms around the drops dissolves only with difficulty. Add a satd. soln. of $(NH_4)_2C_2O_4$ in portions of 25-10 cc. until the yellow ppt. has coagulated and the supernatant soln. is clear and colorless. Allow to stand overnight, filter, ignite and weigh. To the filtrate add more oxalate and heat to see if pptn. was complete. In the final filtrate, the Cb can be pptd. by making ammoniacal and boiling. This ppt. yields Cb_2O_3 on ignition. By following the above procedure in 23 test analyses, the max. error did not exceed 1 mg. in 14 tests, 2 mg. in 4 tests, 3 mg. in 3 tests and 4 mg. in 2 tests. A slight modification of the above procedure is recommended for the detection and identification of Ta and Cb.

W. T. HALL

An uncommon indicator. WALTER PARRI. *Giorn. farm. chim.* **74**, 225-30 (1925).—Formaldehyde *n*-nitrosophenylhydrazone is colored red by acids, orange by the mono-salts of weak polybasic acids and yellow by alkali. It is not altered by weak bases, except NH_3 . CO_2 , CS_2 and all neutral salts of strong or moderately strong acids except K_2CO_3 give an acid reaction. It is of particular advantage for the detn. of alkali in alkaloids, of phenols, of impurities in drugs, e. g., aminophenol in phenacetin, etc. It has the disadvantage of pptg. heavy metals and of being altered by heating with acids and alkalies.

MARY JACOBSEN

Sodium sulfide as reagent. ERNST RICHTER. *Pharm. Ztg.* **70**, 1739 (1925).—An aq. soln. of $Na_2S + 9H_2O$ is preferred to one of H_2S because of the greater stability of the former.

W. O. E.

Sensitive Congo paper. F. W. HORST. *Z. angew. Chem.* **38**, 947 (1925).—For the prepn. of a sensitive paper the com. dye should be recrystd. from hot H_2O , $NaCl$ being used to salt it out, then pptd. from hot H_2O by HCl , washed and redissolved in hot dil. aq. NH_3 , this soln. being used to dye a pure filter paper. Paper so prepd. is sensitive to 0.0003 *N* HCl .

WM. B. PLUMMER

The analytical chemistry of indium. J. HEYROVSKY. *Chem. Listy* **19**, 168-72 (1925).—In deposits reversibly on the dropping Hg cathode from acid and slightly basic solns. The potential corresponding to 1 M soln. of In^{+++} is -0.503 v. and changes by approx. -0.022 v. for each tenfold diln. Traces of In in presence of certain other metals can be detd. by this method with a precision of 10% at a diln. of 10^{-4} *N*, i. e., 0.01 mg. In per 25 ml. soln. As an example, 0.0001% In in Zn can be detected. In strongly alk. solns. In exhibits a weakly acidic character. True solns. of indates formed at first are slowly hydrolyzed, depositing $In(OH)_3$. The equil. soln. in *N* $NaOH$ contains 0.25 equiv. In per l. The ion product of basic dissociation of freshly prepd. $In(OH)_3$ is 10^{-33} ; that of an aged prepn. is 10^{-35} . The ion product acid dissociation in an equil. prepn. is approx. 0.25×10^{-14} .

FRANK C. KRACEK

A method for the spectro-photometric determination of fluorescent substances. RENÉ FABRE. *Bull. soc. chim.* **37**, 1304-10 (1925).—The intensity of the fluorescence spectrum of solns. is not proportional to the concn. but reaches a max. at a certain definite concn. By measuring the intensity of a given soln. and then again after dilg. it is possible to det. its concn. In this way it is possible to est. the quantities of dissolved hydrastinine, quinine, quinidine and fluorescein, for example.

W. T. H.

Determination of silicic acid in fluorspar by treatment with sulfuric acid. H. MENDE. *Chem.-Ztg.* 49, 921(1925).—Fuse 1 g. of finely powdered mineral with 6 g. NaKCO_3 . Ext. with hot water and wash thoroughly. Neutralize the soln. with HCl , using an indicator. Add 10 g. $(\text{NH}_4)_2\text{CO}_3$ and 30 cc. of 25% ammoniacal ZnO soln. Heat in a covered Pt or porcelain dish until danger of loss by effervescence is over, then remove the cover glass, evap. to dryness and heat at 140° for an hr. Treat the residue with water and filter off the insol. Zn silicate. Ignite this residue, treat it in a porcelain dish with enough dil. HCl to decompose it, evap. with H_2SO_4 until SO_3 fumes are obtained, dil., filter and weigh the SiO_2 , correcting with HF as usual. This procedure is a slight modification of the well-known Berzelius method and gives somewhat higher values, which are assumed to be more accurate. W. T. H.

Rapid method for the determination of phosphoric acid. ROBERT F. LE GUYON AND R. M. MAY. *Bull. soc. chim.* 37, 1291-3(1925).—The method, suitable for the detn. of phosphates in urine, depends upon pptn. of Ag_3PO_4 in the presence of NaOAc , dissolving of the well-washed ppt. in HNO_3 and titration of the Ag content by the Volhard method. W. T. H.

Determination of small quantities of halogen and of sulfur. O. WAGNER. *Z. angew. Chem.* 38, 1068(1925).—Natural benzaldehyde is free from Cl but the artificial product is likely to contain it. By using the micro app. of Pregl it is possible to det. accurately a few thousandths of 1% Cl in 0.2 g. of substance decomposed with fuming HNO_3 in a Carius tube, eventually weighing as AgCl . Similarly, the S content of Texas oil can be detd. as BaSO_4 with 0.2 g. of substance. These methods are described to illustrate the advantages of micro-analysis. W. T. H.

Argentometric titration of iodide. I. M. KOLTHOFF, *Pharm. Weekblad* 62, 1309-12(1925).—To 25 cc. of iodide soln. (0.1N) add 1 drop of 0.1N KIO_3 and a few drops of 4 N H_2SO_4 . A sepn. of I imparts a yellow color to the soln. Add starch soln. and 5-10 cc. of 2 N $(\text{NH}_4)_2\text{CO}_3$ and titrate with 0.1 N AgNO_3 . The blue soln. becomes gray and the AgI ppt. is at first gray from adsorption of starch iodide. Toward the end of the titration shake vigorously after each addn. of AgNO_3 and a pure yellow ppt. is finally obtained. The end point is sharp within 0.1 cc. The advantage of this method is that practically all of the I is pptd. before the other halogens. The filtrate contains the Br and Cl . Accurate results may be obtained in acid medium even with great dilns. of iodide. More than 3% bromide or 20% chloride diminish the accuracy of the detn. A. W. DOX

Apparatus for the volumetric determination of small quantities of oxygen and carbon monoxide in nitrogen or other inert gases. J. GRISSLER. *Z. angew. Chem.* 38, 948-9(1925).—Separate samples of CO_2 -free gas are used for the O and CO detns., H being added in the O detn. while O is added for the CO detn., combustion being carried out in each case in a SiO_2 capillary elec. heated and contg. a Pt wire as catalyst. Since greater contractions for a given amt. of O or CO are thus obtained than in the ordinary procedure, and since the buret used has a capacity of approx. 380 cc., an accuracy of 0.01% is said to be obtained. WM. B. PLUMMER

A quick method for the determination of ozone. H. B. McDONNELL. *Ind. Eng. Chem.* 18, 135(1926).—The gas is allowed to flow into 30 cc. of 1% KI soln., contg. 5 cc. of 0.01 N $\text{Na}_2\text{S}_2\text{O}_3$ and starch, until a blue color develops and the time detd. with a stop-watch. The method is applicable to low concns. of O_3 in air and can be used for the detn. of small quantities of other gases such as Cl_2 which react with KI . W. T. H.

Determination of hydrogen and methane in illuminating gas. MAX PERNECKER. *Chem.-Ztg.* 49, 1073(1925); 1. Orr. *Ibid* 1073-4. WILHELM STEUER. *Ibid* 1074; cf. C. A. 20, 656.—This somewhat polemical discussion may be of interest to chemists because it represents 3 different viewpoints and opinions with respect to the best way to det. H_2 and CH_4 in the presence of considerable CO . W. T. H.

Successive potentiometric titration of copper and iron in metallurgical products. T. F. BUEHRER AND O. E. SCHUPP, JR. *Ind. Eng. Chem.* 18, 121-4(1926).—When CrCl_2 is used as the reducing agent, either by direct titration or by residual titration with $\text{K}_2\text{Cr}_2\text{O}_7$, the detn. of Cu and Fe is accurate and rapid, either singly or together. The Fe is reduced to the bivalent condition before any Cu is reduced. Then the bivalent Cu is reduced in 2 stages but the reduction of the univalent Cu starts before all the bivalent Cu is reduced so that the entire reduction has to be accomplished. With this method the time required for the detn. of Cu and Fe in metallurgical products is shortened considerably. W. T. H.

Detection of traces of gold by spectrography. PIERRE JOLIBOIS AND ROBERT BOSSUET. *Bull. soc. chim.* 37, 1297-1304(1925).—Very often in assaying for gold, tiny fragments of material are obtained which are assumed but not definitely proven

to be Au. By means of photographing the arc spectra of an alloy contg. Au and comparing the rays obtained in the ultra-violet region with similar spectra of pure C, Fe and pure Au it is possible to identify 1 mg. of Au from a mass of 50 g. of Pb. To detect Au in soln. a little HgCl_2 or Bi salt can be added and then H_2S introduced. This ppt. placed in a cavity on the C-terminal of the arc will suffice to show the characteristic Au spectrum when only 0.001 mg. of Au is present. For the examn. of minerals, it is best to add a little Ag, obtain a Pb button in the usual way, and cupel the button before applying the test. W. T. H.

Estimation of cadmium in copper. C. BLAZEY. *Chem. Eng. Mining Rev.* 17, 502-3(1925).—When Cu is heated in H_2 as in the detn. of oxides by the Ledebur method, all of the Cd distills away from the Cu and condenses in the cold part of the tube and can be analyzed easily. It requires several hrs. to remove all of the Cd from a large sample but the method may be useful. W. T. H.

Electrolytic method for the determination of zinc in ores. R. E. SULLIVAN AND H. S. LUKENS. *Chem. News* 131, 321-4(1925).—Add 10 cc. of concd HNO_3 to 0.3-0.4 g. of moistened ore powder, heat 5 min., dil. to about 20 cc. and add enough of a soln. of 20 g. KOH in 100 cc. of water, to ppt. all the Fe and leave the soln. distinctly alk. Filter and add the remainder of the KOH soln. to the filtrate. Dissolve the $\text{Fe}(\text{OH})_3$ ppt. in HCl and reppt. with NH_4OH , adding this filtrate to the former. Electrolyze the KOH soln. with 2 Pt anodes and a 40-cc. rotating Ni crucible as cathode, using a current of 0.8 amp. at 5-6 v. At the end of 45 min. test a little of the soln. for Zn with HCl and $\text{K}_4\text{Fe}(\text{CN})_6$. W. T. H.

The chemistry of basic slag. I. The determination of fluorine in basic slag. R. G. WARREN, C. T. GIMINGHAM AND H. J. PAGE. *J. Agr. Sci.* 15, 516-28(1925).—A new method for the detn. of F in basic slag is proposed. The F content and citric soly. of basic slags are compared. The method in brief is as follows: Fuse 5 g. of slag and 6 g. of NaKCO_3 . Extract the melt in the H_2O and conc. the extract to approx. 100 cc., cool, add 3-4 g. solid $(\text{NH}_4)_2\text{CO}_3$, and let stand overnight. Filter and wash with 5% $(\text{NH}_4)_2\text{CO}_3$ soln. Retain the residue. Evap the filtrate to dryness on the water bath, take up with 50 cc. H_2O , filter and again take to dryness. Next add 50 cc. H_2O satd. with phenolphthalein, and titrate hot, using 4N H_2SO_4 at first. The color of the indicator must not be allowed to fade completely as loss of HF might occur; boil after each addn. of acid in a covered beaker. When the end point is nearly reached transfer to a 100-cc. beaker and complete the titration with 0.1N acid. Then evap. the soln. to a vol. of 50 cc. To the well-stirred hot soln. add 0.6 g. of powdered Ag_2SO_4 . Set aside overnight, in the dark. Filter in the dark into a 100-cc. flask through a double 7 cm. filter paper. Twenty cc. of H_2O should suffice to wash the ppt. Add 10 cc. of H_2SO_4 (d. 1.55) and 3 cc. H_2O_2 . No brown color should develop. Finally, add 10 cc. of $\text{Ti}(\text{SO}_4)_2$ and adjust the soln. to a vol. of 100 cc. Use a standard of $\text{Ti}(\text{SO}_4)_2$ with the same quantity of reagents for comparison in a Kober instrument.

R. B. DEEMER

Determination of manganese in alloy steels rich in cobalt. KROPP. *Chem.-Ztg.* 49, 1074(1925); ERNST KLIMA. *Ibid.*—The objections to adding Mn to solns low in Mn are outlined and the difficulties when Co is present pointed out. W. T. H.

Analysis of some lithium minerals. A. GUNTZ AND F. BENOIT. *Bull. soc. chim.* 27, 1294-7(1925).—In the SiO_2 detn. the results are likely to be low unless precautions are taken to overcome the effect of F. Thus 50.4% SiO_2 was obtained by the Berzelius method using $(\text{NH}_4)_2\text{CO}_3$ and ammoniacal Zn soln. and 49.80% SiO_2 by the method ordinarily used. For the detn. of F it is advised to fuse the mineral with KOH and to titrate the resulting K_2SiF_6 with KOH soln. For the H_2O detn. it is necessary to remember that the presence of F causes evolution of HF when the mineral is heated so that CaO should be provided to remove F before absorbing the H_2O . For the detn. of alkalis, the Berzelius method of decompn. with HF and H_2SO_4 is recommended, but it is well to heat the sulfates strongly to make Fe and Al insol. For the Li detn., ppt. as LiF by means of 20% NH_4 in 2% NH_3 soln., weighing finally as LiF or Li_2SO_4 . Then after the removal of the SO_4 — the usual HClO_4 method can be used for detg. K. The wt. of Na_2SO_4 can be estd. by the weighing of the K_2SO_4 and Na_2SO_4 obtained after the Li detn. In the analysis of minerals contg. PO_4 — a similar treatment can be used after removing the PO_4 in the original soln. obtained from the HF- H_2SO_4 treatment, by means of PbO added to the slightly acid soln. Then the dissolved Pb can be removed as PbSO_4 . W. T. H.

Analysis of zinc minerals. ANON. *Bull. féd. ind. chim. Belg.* 4, 323-33(1925).—The modification of the Na_2S volumetric method as approved by the Association Belge de Standardisation is described, instructions also being given for dissolving various

Zn products. After elimination of the H_2S and Fe groups the Zn is titrated with Na_2S soln. (20 g./l. of $Na_2S \cdot 9H_2O$), spot tests on paper impregnated with basic $PbCO_3$ being used to det. the end point. The titration must be carried out simultaneously (2 burets) with one vs. a standard Zn soln. to insure accuracy. Detailed directions and discussion are given.

WM. B. PLUMMER

The titration of mercury with potassium cyanide, lead with arsenate and iron with thiosulfate in reply to a paper by E. Rupp with W. Wegner and P. Maiss. KARL JELLINEK and JOHANNES CZERWINSKI. *Z. anorg. allgem. Chem.* **149**, 359-76(1925).—When KCN is added to a boiling hot soln. of $HgCl_2$ contg. phenolphthalein the colored end point is obtained when all the $HgCl_2$ has been converted to $Hg(CN)_2$. The reaction between $HgCl_2$ and pure KCN is complete at the boiling temp. If the KCN contains, as it usually does, a little KOH and K_2CO_3 then some $Hg(OH)CN$ and some $KHCO_3$ are formed so that if the KCN has been standardized against $AgNO_3$, less of the soln. is required than corresponds to the KCN content; but if the KCN has been standardized by acidimetric titration, apparently too much of the soln. is needed in the titration of $HgCl_2$. To avoid the error due to carbonate, titrate with the KCN soln. to the end point, add a little HCl soln. to decompose $KHCO_3$ and again titrate with KCN soln., allowing for the HCl added. Further expts. in the titration of Pb solns. with alkali arsenate indicate that K_3AsO_4 is unsuitable but that the titration succeeds with Na_3AsO_4 soln. standardized against pure Pb soln. In the titration of $FeCl_3$ with $Na_2S_2O_3$, the amt. of $Na_2S_2O_3$ required varies with the H-ion concn. of the soln. Equiv. amts. of $FeCl_3$ and of $Na_2S_2O_3$ are involved if the titration is accomplished at 60-65° in a soln. contg. 2 milli-equivalents of HCl and a final vol. of 80 cc. and 0.25 cc. is deducted from the final $Na_2S_2O_3$ reading. By using methylene blue and fuchsin as indicators and finishing the titration at the boiling temp., a somewhat better titration value is obtained.

W. T. H.

Determination of metals dissolved in mercury. Rapid method of purifying mercury. A. S. RUSSELL and D. C. EVANS. *J. Chem. Soc.* **127**, 2221-30(1925).—By treating Hg contg. Zn, Mn, Cd, Th, Sn, Pb, Cu, Cr, Fe or Bi with dil. H_2SO_4 and $KMnO_4$, the Hg is freed from the foreign metals and from the vol. of $KMnO_4$ the amt. present can be estd. If a mixt. of 2 metals such as Sn and Pb is dissolved in Hg and the resulting amalgam titrated with $KMnO_4$ in dil. H_2SO_4 soln. the compn. of the mixt. can be computed from the original wt. and the vol. of $KMnO_4$ required. The end point is easy to find as bubbles begin to form on the surface of the Hg.

W. T. H.

A new and very sensitive method for detecting, separating and determining bismuth. A. GIRARD and E. FOURNEAU. *Compt. rend.* **181**, 610-11; *Bull. soc. chim.* **37**, 1669-73; *Reperl. pharm.* **36**, 353-4(1925).—It is known that BiI_3 gives red products with natural alkaloids. By substituting certain synthetic bases for the natural alkaloid it is possible to obtain highly colored products which are sol. in benzene. Several of these synthetic bases have been tested and the most promising appears to be tetraacetylammmonium hydroxide. With BiI_3 the following compd. is formed, $(C_{16}H_{32})_4NOBiI_3$. Certain oxidizing agents, such as ferric iron, interfere with the test but with Fe the difficulty can be overcome by adding a soln. contg. formic acid, NH_4 formate, KI and $NaHSO_3$. The method of prepg. the reagent and directions for applying the test will be published elsewhere.

W. T. H.

The determination of small quantities of other elements in tungsten. K. AGTE, H. BECKER-ROSE and G. HEYNE. *Z. angew. Chem.* **38**, 1121-9(1925).—Based largely on the work of Arnold (*C. A.* **8**, 3165; **9**, 422), a sample of scheelite was analyzed and found to contain besides 63.3% WO_3 , 15.04% SiO_2 , 10.72% Fe_2O_3 and 9.51% CaO , some 17 other constituents. The WO_3 and metallic W prepd. from the scheelite were tested for each of the constituents found in the mineral and for C, N, O, and S in addn. The method of analysis is outlined and the limit of sensitiveness detd. in each case. The WO_3 was 99.75% pure and the W much purer.

W. T. H.

The carbon error in the quantitative deposition of nickel and iron from complex oxalate electrolytes. P. K. FRÖLICH. *Analyst* **50**, 444-5(1925).—Reply to comments on his paper (*C. A.* **19**, 2614).

W. T. H.

The electrometric determination of iron with bromate. OSCAR COLLENBERG and KARL SANDVED. *Z. anorg. allgem. Chem.* **149**, 191-202(1925).—In studying the electrometric titration of ferrous salts with $KBrO_3$, Kolthoff came to the conclusion that the method was not sufficiently accurate, but the present studies show how the conditions can be changed so that the titration can be accomplished without undue delay and with satisfactory accuracy. The reaction between ferrous salt and bromate is very slow in dil. acid solns. but the rate of reaction can be accelerated by raising the temp. to 50°, by adding a catalyzer, best $CoCl_2$, and by carrying out the titration in

2 *N* HCl soln. To the hot soln. add a slight excess of 0.2 *N* SnCl₂ and 5 cc. of 6% CoCl₂ soln. Add 10–20 cc. of concd. HCl per 100 cc. of soln. and titrate with 0.1 *N* KBrO₃. From changes in electrode potential the end of the oxidation of the stannous Sn and the end of the oxidation of ferrous Fe can be easily detd. The change at the end point of the Fe titration is about 670 millivolts and between 120 and 180 millivolts at the end of the Sn titration. A bimetallic electrode system can be used if desired.

W. T. H.

The complete analysis of brass. IV. Magnesium, manganese, copper, arsenic, sulfur and cadmium. C. C. D. *Metal Ind.* (London) 27, 599–600(1925).—It is recommended to det. Mg as Mg₂P₂O₇ after pptn. as MgNH₄PO₄ in strongly ammoniacal NH₄Cl soln. prior to the removal of Mn, Cu and Cd. The persulfate method with a sep. sample is recommended for Mn. For the Cu, the iodide method is advocated. For As, distn. of AsCl₃ and subsequent iodometric titration are described. For S, fusion with KClO₃ and Na₂CO₃ is preferred to oxidation in the wet way. For Cd, it is advised to remove Cu by electrolysis, and ppt. all of the CdS and some ZnS in the residual soln. by means of H₂S, repeating the pptn. until pure CdS is obtained which can be converted easily to CdSO₄ and weighed.

W. T. H.

Chemical study of basic eruptive rocks. I. A. ATANASIU. *Bul. chim. soc. română științe* 27, 17–36(1924).—The method recommended for the analysis of basic rocks contg. Ti is essentially as follows: Fuse 1 g. with 7 g. Na₂CO₃ and 1 g. Na₂SO₄, evap. the melt in the dil. H₂SO₄ till the SiO₂ is granular, take up in H₂SO₄, filter, ignite, volatilize SiO₂ with HF, fuse the residue with Na₂CO₃, take up in HCl, ppt. ZrO with NH₄OH, filter, weigh and in the filtrate from the ZrO ppt. BaO with H₂SO₄. In the filtrate from SiO₂, BaO and ZrO, ppt. Ti and P by adding H₂SO₄ to the nearly neutral soln. and boiling. Filter, dissolve in concd. H₂SO₄, reduce with Zn and det. TiC₂ by titration with KMnO₄. Oxidize the filtrate from TiO₂ and P with Br and HCl, in an aliquot portion ppt. Fe and Al by means of AcONa, titrate Fe with KMnO₄ as usual, calc. Al₂O₃ by difference, and ppt. Mn in the filtrate as Mn₂O₃ by means of Br and NH₃. In another aliquot from the TiO₂ ppt., ppt. Fe and Al with NH₃ and det. CaO with (NH₄)₂C₂O₄ and MgO with Na₂HPO₄ as usual. Det. S and P on a sep. portion (2 g.) of sample as follows: fuse with 8 g. Na₂CO₃ and 2 g. KNO₃, dissolve in 150 cc. hot water, filter, acidify with HCl, remove SiO₂, add 0.5 g. FeCl₃, ppt. FePO₄ by nearly neutralizing with NH₄OH and boiling. In this ppt. det. P by a known method (preferably volumetrically), and in the filtrate ppt. S as BaSO₄. Analyses, carried out by this method, of a no. of basic eruptive rocks from the Eastern Carpathians are tabulated and commented.

A. PAPINEAU-COUTURE

Photometric methods for studying and estimating suspensions of dusts, fumes and smokes. PHILIP DRINKER, R. M. THOMSON AND JANE L. FINN. *J. Ind. Hyg.* 7, 567–76(1925).—The Tyndallmeter with Macbeth illuminometer or measurement by transmitted light or by a contrast photometer method such as that developed by Owens provides accurate, convenient and rapid methods of estg. suspensions. Although concn. cannot always be detd., the readings give reliable indices of the size and dispersion of the particles.

C. M. SALLS

Destruction of organic matter by hydrogen peroxide. Application in toxicology. C. A. GRAU. *Rev. facultad ciencias* 3, No. 2, 131–2(1925).—Na perborate is used instead of H₂O₂.

MARY JACOBSEN

An accurate general iodometric method for the quantitative determination of the carbonyl group in organic compounds. E. G. R. ARDAGH AND J. G. WILLIAMS. *J. Am. Chem. Soc.* 47, 2983–8(1925).—The method is based upon the formation of a phenylhydrazone, the excess of phenylhydrazine being detd. by titration with I₂. The hydrazone reaction is carried to completion by producing the conditions shown to be necessary in a preceding paper (*C. A.* 20, 374). Attention is also directed to the conditions to be maintained for an accurate titration of phenylhydrazine by I₂, as well as to the necessity of using air-free water and an atm. free from O to avoid oxidation of the phenylhydrazine. The general method is given in detail, also detailed calcs. for a typical compd. (acetaldehyde) and results for a number of others. Also in *Trans. Roy. Soc. Can.* 19, 73–4(1925).

J. W. SHIPLEY

Microanalytical method for the determination of lactic acid and lactates in pure solutions. KLAUS HANSEN. *Tids. Kemi Bergv.* 5, 172–4, 187–9 (1925).—The following method will give accurate results within very wide limits of concn. but is adaptable to pure solns. only. Measure out into a 100-cc. Erlenmeyer flask by means of a microburet 5 cc. of a soln. contg. 7.6237 g. K₂Cr₂O₇ per l., 1 cc. of which will correspond to 3.5 mg. of lactic acid. Add the soln. to be examd., at least 5 cc., or if necessary dil. to 5 cc. with H₂O. Add 15 cc. of 40% H₂SO₄ from a buret.

Insert a rubber stopper and keep the stoppered flask for 1 hr. at 70° in a thermostat. Dil. with 50 cc. H₂O, add 2 cc. of 10% KI and titrate with Na₂S₂O₃ from a microburet. If the amt. of lactic acid corresponds to more than 3 cc. of the K₂Cr₂O₇ soln. the amt. of the latter should be doubled. With quantities of lactic acid below 0.1 mg. the method is unsuitable.

C. A. ROBAK

Determination of formaldehyde. E. SCHULEK. *Ber.* 58B, 732-6(1925).—Two methods are proposed which are based on the KCN reaction already used by Romijn. HCHO reacts with KCN to form HCH(OK)CN which hydrolyzes forming HCH(OH)-CO₂K and (NH₄)₂SO₄. The excess of the KCN can be detd. by titration with AgNO₃. To 50 cc. of 0.1 N KCN and about 5 cc. of 30% MgSO₄ soln. (as catalyzer) add 5-10 cc. of the formaldehyde soln. contg. 10-50 mg. HCHO. Stir well and after 1-2 min. add 1 g. of NH₄Cl (to dissolve the Mg(OH)₂ formed), a little KI and 2-3 drops of 6 N NH₄OH. Titrate quickly with AgNO₃ soln. till a turbidity persists for 1-2 min. If less than 10 mg. of formaldehyde is present, it is better to proceed as follows: To 10-25 cc. of 0.1 N KCN soln. add 5-10 cc. of the formaldehyde soln. while stirring. After 3 min. make the soln. strongly acid with concd. HCl and introduce aq. Br₂ until the soln. assumes a permanent yellow coloration. Add 1-2 cc. of 5% phenol soln. to react with the excess Br. Add KI and titrate with thiosulfate soln. W. T. H.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY

Magnetic rotatory power of some paramagnetic minerals at very low temperatures. H. KAMERLINGH ONNES, JEAN BECQUEREL AND W.-J. DE HAAS. *Compt. rend.* 181, 838-41(1925).—B. showed (*C. A.* 3, 859) that the increase in magnetic rotatory power of certain Di minerals (tysonite, parisite) from lab. temps. to that of liquid air is approx. inversely proportional to the abs. temp. Combination of this with Curie's law on paramagnetic susceptibility would indicate that the rotatory power of the crystals is proportional to their susceptibility, which has been confirmed for temps. down to 20° abs. (*C. A.* 4, 861). Further expts. with tysonite showed the proportionality to hold for temps. down to 4.2° abs. (boiling He). The ratio of the rotations seems to decrease slightly from the violet to the red end of the spectrum, but the accuracy of the measurements is not sufficient to state it definitely. The susceptibility of tysonite is therefore considered to follow Curie's law, with a slight correction for Weiss's law. Parisite and bastnaesite follow the same law. Xenotime (Er spectrum) gives much more complex effects owing to numerous bands very sensitive to the magnetic field and to general absorption throughout the spectrum. There are apparently 2 essentially different polarization phenomena involved in magnetic rotation: one, generally positive, depending on the Zeeman effect, the other negative, apparent in paramagnetic substances, resulting from unsymmetrical absorption of circular vibrations in opposite directions, caused by orientation or distortion in the field. The 2 effects are additive, and either one can predominate.

A. PAPINEAU-COUTURE

Some points of relationship between artificial ferro-nickels and a nickeliferous iron of meteoric origin. MARCEL PESCHARD. *Compt. rend.* 181, 854-5(1925).—The Chinitla meteorite contains 9.05% Ni and less than 1% impurities, which consist of localized masses of schreibersite and of Fe sulfide. On etching a polished section

with HNO_3 , microscopic examn. shows a very pronounced segregation of kamacite and taenite. From magnetic measurements P. deduces the Ni contents of kamacite and taenite as 6.9–7.0% and $32.8 \pm 0.2\%$, resp. A comparison of the magnetic properties of the meteorite and of an artificial Fe-Ni having the same compn. shows that on annealing the meteorite 15 hrs. at 1000° and cooling in 40 min. it is brought to the same state as the artificial Fe-Ni, and by reheating to 1000° and cooling in 21 days it is restored to its original state. P. concludes that meteorites are in a state of physico-chem. equil., while artificial Fe-Ni's are in a state of metastable equil. A. P.-C.

The electric conductivity of the ore veins at the Kongsberg silver works. M. MORTENSON. *Tids. Kemi Bergv.* 5, 209–13(1925).—A proportionality was observed between the cond. of the surrounding rock and the Ag content of the veins, in accordance with the theory of Münster and Vogt on the genesis of the Ag. C. A. ROBARK

Zonolite: utilizing a useless mineral. E. N. ALLEY. *Eng. Mining J.-Press* 120, 819–20(1925).—The com. development of a large deposit of *altered phlogopite* in Montana brings out many uses for the treated material. The dark heavy mineral when roasted swells to about 15 times its original vol. and becomes a light flaky material of golden leaves sepd. by air spaces. It is a silicate of Mg and Al contg. a little Fe. Exptl. work indicates the following uses for the treated material: insulator for heat or cold, decorative material for plastered walls, fireproof roofing; component of wall paper, wall board, paint, cement products and pipe and boiler coverings; fireproof and insulating packing, in greases and lubricants and as a gold-bronze paint. W. H. B.

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, R. S. WILLIAMS

A review of metallurgical progress. S. B. GOODALE. *Blast Furnace & Steel Plant* 14, 37–40(1926). E. J. C.

Blast-furnace progress in 1925. H. E. McDONNELL. *Blast Furnace & Steel Plant* 14, 16–7(1926). E. J. C.

The purchasing of manganese ores. R. NAVET. *Rev. universelle mines* 8, [7], 227–40(1925).—Based on their role in the reactions of the metallurgical process, methods are derived for calcg. the value of Mn ore contg. different amts. of Mn, SiO_2 and Fe. By such calcns. an ore can be evaluated economically from the amt. of Mn and of these secondary ingredients. C. C. DAVIS

The proper use of lime to alkalize mill currents. C. T. HENDERSON. *Eng. Mining J.-Press* 120, 1016(1925).—H. shows that the proper type of milk of lime for flotation work is made by slaking high-Ca quicklime with at least 10 times the amt. of water theoretically required for hydration. Calcined dolomite is not satisfactory. The lime serves 3 purposes: It neutralizes the temporary hardness of the water used in pulp making; more is consumed in neutralizing any acidity in the ore; and the remainder creates the necessary alk. condition in the circuit. W. H. BOYNTON

Viscosity of mill solutions. F. C. BOND. *Mining & Metallurgy* 7, 15–6(1926).—Little attention has been paid in cyanide milling to the effect of the viscosity of the mill soln. on extn. speed. Viscosity varies with the amt. of dissolved salts present as impurities which build up to a max. depending on the character of the ore, the grade

of cyanide used, the lime and salts added, and the impurities in the water. Each of these factors is discussed. A viscosity detn. of sufficient accuracy is made by attaching the bottom of a 50-cc. buret with a short rubber tube, a glass tube blown to a capillary of such size that it will deliver 50 cc. of water in a steady stream in about 120 sec. The buret is filled with distd. water at a known temp., the buret cock is opened completely, and the time recorded that the water takes to drain to the 50-cc. mark. The sample is similarly treated and corrected to the temp. of the water by the formula: $\text{Time} = \text{time observed} (1 \pm 0.037t)$, where $t = \text{temp. difference}$, and Time is the time in sec. for the 50 cc. of soln. to drain from the buret. The sign is + if the temp. of the mill soln. is higher than that of the water and - if lower. The no. of sec. required by the soln. divided by the no. of sec. for distd. water = sp. viscosity of the soln. Duplicate detns. check within 2%. This method is much simpler than the detn. of the elec. cond. of the soln.

W. H. BOYNTON

New stack for ferrophosphorus. ANON. *Iron Age* 116, 1731-2(1925).—A new blast furnace at Rockdale, Tenn., for the production of ferrophosphorus is described and illusd. The gas is removed from the furnace by 2 4 ft (1 2 m.) downcome pipes lined with firebrick and extended to the brick-lined dust catcher with a diam. of 12 ft. (3.6 m.) and a height of 16 ft (4.8 m.).

W. H. BOYNTON

The developments in pig-iron production within the last decade with respect to the technical and chemical-metallurgical points of view. KONRAD HOFMANN. *Z. angew. Chem.* 38, 1058-64, 1085-8(1925).—A review of the latest theoretical and practical developments in the operation of blast furnaces. The various reactions which take place are described and illustrated. A diagram is shown from which can be detd. the amt. of CO that theoretically can be used for reduction of FeO. In actual practice the CO content of the furnace is much higher. Working methods are given by which ideal conditions in the furnace during the operation can be approached. The recent developments in the construction and operation of elec. furnaces are given in detail.

C. A. ROBAK

The reaction between manganese and iron sulfide. C. H. HERTY, JR. AND O. S. TRUE. *Blast Furnace & Steel Plant* 13, 492(1925).—Expts. were carried out to det. the reversibility of the reaction $\text{Mn} + \text{FeS} = \text{MnS} + \text{Fe}$. Electrolytic Fe is melted in a ZrO_2 crucible and in various runs Mn and MnS are added to give 1, 2 and 4% Mn with 0.5% S in each, while in others Mn and FeS are added to give a 2nd series with the same proportions of Mn and S. Results show that MnS even with an excess of Mn forms FeS. The greater the excess of Mn the lower the S, whether it is originally present as MnS or FeS. The authors conclude that the reaction is reversible, the *equil. const.* being $K = [(\text{MnS}) \text{ metal}] / [(\text{FeS}) \text{ metal} \times (\text{Mn}) \text{ metal}]$, from which it follows that as the concn. of Mn is raised the ratio (MnS) metal/(FeS) metal must increase.

H. STOERTZ

Controlling molding sand in a radiator shop. II. H. W. DIETERT AND W. M. MYLER, JR. *Foundry* 54, 9 12(1926); cf. *C. A.* 19, 2021.—The tentative tests of the Joint Committee on Molding Sand Research of the Am. Foundrymen's Assoc. are briefly discussed and a special strength test, regarded by the authors as reliable and more rapid, is described. The prepn. of the sample, the app. employed in the tests, and the advantages of the special test in connection with testing of molding sands for radiator casting are pointed out. The strength rammer with mold and bottom rammer, and the strength test machine are illusd. and comparative test values of some sands tabulated.

W. H. BOYNTON

The Swedish Institute of Metallography. ANON. *Industriidningen Norden* 54, 406-7, 418-9, 421-2(1925).—A review of the progress and development of the Institute during the 5 years since it was founded, with a brief report of some of the more important scientific results attained.

C. A. ROBAK

Pearlitic cast iron. BERNARD BUFFET AND ALPHONSE ROEDER. *Bull. soc. ind. Mulhouse* 91, 622-34(1925).—A discussion of its structure and properties. B and R. recommend the general adoption of the shock test instead of the tensile-strength detn. for this grade of Fe.

A. PAPINEAU-COUTURE

Comparative study of the corrosion of cast irons in sulfuric acid of different strengths.

G. DELBART. *Compt. rend.* **181**, 786-8(1925); cf. *C. A.* **19**, 3244.—Twenty-seven different cast irons were immersed in H_2SO_4 of the following strengths: 1.6, 80, 85 and 92.6% SO_3 . The analyses of 10 samples are given. In weak acid for 72 hrs. these showed that P up to 1.7%, 4% Si, or 3% Mn tended to increase the soly., S up to 0.2% did not have much effect, and the semi-steel, white Fe and malleable Fe dissolved least. The most resistant irons were normalized to destroy internal stresses, and compared with steels in the weak acid. The gray irons were much more sol. than the steels, but the malleable and white irons showed about the same loss as the medium-hard steels, though more than the soft steels. In acid contg. 80% SO_3 for 240 hrs. the results were similar. Acid contg. 85% SO_3 gave irregular results, but in general the less pure irons (except the sample with high Mn) showed the highest loss, while the purer irons (except malleable Fe) gave better results. With the strongest acid the differences were less, the purer irons in general being slightly better. It is concluded that steel is preferable to cast Fe for corrosion resistance in most cases. A few special irons give results similar to those obtained from steel, but they are generally weak and difficult to cast. GEO. F. COMSTOCK

Correlating gray-iron tests. J. W. BOLTON. *Foundry* **53**, 912-5, 959-61(1925).—Some common mech. tests for cast Fe, and their correlation to the structure and chem. compn. are considered. The strength varies inversely with the graphite content. The assumption of a ferrite network within the graphite seems plausible. The strength drops with increasing C content more rapidly when the C is high. Increased pearlite causes greater Brinell hardness, but the strength is affected as much by graphite and grain-size. Heat-treatment of gray Fe may increase the strength 50%. Cr and high Mn decrease graphitization; Si and high C increase it; Ni strengthens the matrix. Increase of section size weakens the Fe more in tension than in transverse loading, on account of piping of thick bars. The ratio of transverse to tensile strength depends on the type of structure. Fractures follow graphite flakes. The highest strength is found with Brinell hardness of 200 to 240, low total C and fine grain-size. High P reduces machinability but helps resistance to wear. Fluidity is not affected by P variation between 0.2 and 0.9%. GEO. F. COMSTOCK

The mechanical properties of steel. WM. H. DALBY. *Engineering* **120**, 625 (1925).—An abstract of a paper presented before the Institution of Civil Engineers, giving the results of tests made with photographic recorders by the looping-in-tension, push-pull and torque-twist methods. A push-pull or a torque-twist cycle gives a curve of characteristic shape called the plastic contour, repeated tests changing the boundaries slightly. Metal fails by slipping, but retains some elasticity even after slipping almost to fracture. The results of X-ray analyses are discussed to explain these phenomena. Reduction of load after failure by slipping gave an elastic response. The plastic contour showed that with reversal of load the elastic property almost disappears. Overstrain in manuf. may account for mysterious failures, and equal elastic properties in tension and compression should always be restored before use. GEO. F. COMSTOCK

Structural diagrams of some special steels. TSUTOM KASÉ. *Science Repts. Tohoku Imp. Univ.* **14**, 453-78(1925); *Chem. News* **132**, 18-9(1926).—The structures of Ni, Mn and Cr steels were investigated by means of the scleroscope, microscope and magnetic and expansion measurements, and the results are presented in tables, diagrams and photomicrographs. Immersion in liquid air transformed austenitic steels of about 20 to 34% Ni to martensite, increasing the hardness and producing an irreversible expansion. Magnetic tests showed that the A_1 transformation is a stepped change in most Ni steels of between 8 and 20% Ni. The structural diagram given for annealed Ni steel shows four fields bounded by lines approx. parallel to the C axis. The Mn steels gave somewhat similar results, except that alloys with over 15% Mn are non-magnetic. Steels with about 5 to 10% Mn are non-magnetic at room temp. but become magnetic on immersion in liquid air. The diagram for Mn steels is similar to that for Ni steels, except that much smaller amts. of Mn are involved. Fe-Cr alloys must contain C in order to harden by quenching in liquid air. Magnetic tests showed that the A_2 point of Fe-Cr alloys decreased with increasing Cr. Cr carbide when dissolved at high temp. in the steel does not sep. at ordinary rates of cooling, and the transformations are correspondingly affected. In steels with 0.7% C the expansion curves showed that the $Ac_{1,2}$ point is raised by increasing Cr. The structural diagram of the Cr steels shows fields bounded by sloping lines, and annealing changes the diagram decidedly. GEO. F. COMSTOCK

Silicon steel. W. E. RUDER. *Blast Furnace & Steel Plant* **13**, 473-5(1925).—R. reviews the development of Si steels and discusses their mech. and magnetic prop-

erties. *Resistivity* increases 11.4 microhms for every % Si, and the soly. of Fe for C is limited to 0.008% with Si up to 5%. The *saturation value* is decreased from $B = 22,300$ for pure Fe to $B = 20,200$ for 4% Si, and the alloy increases in brittleness. Grades of Si steels are discussed.

H. STOERTZ

Influence of some elements on the spheroidization of carbides in steel. TOMIMATU ISIHARA. *Sci. Repts. Tohoku Imp. Univ.* 14, 377-90(1925).—Previous work on the causes of spheroidized cementite is first discussed. Heating must be at least up to the A_1 point to permit spheroidization, or the sepn. of lamellar pearlite must be effected by mech. treatment. Spheroidized cementite is less likely to occur in eutectoid steel than in other steels. The temp. range above A_1 in which spheroidal cementite appears is larger if the grain-size is coarse, or if the soln. of carbide is hindered by the presence of other elements. Lamellar steel specimens were heated to different max. temps. and cooled at 2° per min. around A_{c1} to study spheroidization. The presence of Mn in steels was found to widen the spheroidizing interval of temp. With const. Mn, it increased slightly with C up to the eutectoid concn., and rapidly above that. Cr increased the spheroidizing interval more than Mn. The spheroidized structure was finer and easier to produce in Cr steels. Cu produced a coarser spheroidized structure, and its effect on the spheroidizing range was intermediate between those of Mn and Cr.

GEO. F. COMSTOCK

Variation with temperature of the resistance to tensile shocks of ordinary mild and hard steels. J. COURNOT AND K. SASAGAWA. *Compt. rend.* 181, 1065-6(1925).—Tests were carried out with an ordinary 30-kg. Charpy pendulum, fitted with a special elec. furnace so that the test bar was ruptured inside the furnace. An extra-mild (C 0.04, Mn 0.57, Si 0.005, S 0.04, P 0.11) and an extra-hard steel (C 0.97, Mn 0.41, Si 0.19, S 0.004, P 0.02) were tested, after annealing 10 min. at 830° and 800° and cooling slowly. The impact energy, T , per unit of useful vol. (in kg./cc.) and the elongation %, A , of this part of the bar were detd. for temps. of $20-800^\circ$. T has a max. at 200° and another at 625° and 700° for the mild and hard steel, resp., with corresponding min. at 500° and 600° . The "mean unitary tension," T/A , was not found to correspond to the breaking load in ordinary tensile-strength tests. Much more complex results were obtained with a steel contg. C 0.62, Ni 25.5%. A. P.-C.

Modern developments in steels resistant to corrosion. W. H. HATFIELD. *Engineering* 120, 657-60(1925).—A paper presented before the Institution of Engineering Inspection. The theories of corrosion are briefly described. The modern conception is that the nature of the first thin oxide film det. the subsequent chem. action. Corrosion tests are always disturbed by accelerating or retarding factors, such as contact of the specimen with a solid body, improper aeration, or change in compn. of the medium. Expts. were conducted with specimens 1 cm. in diam. weighing 50 g. polished with 00 emery, and totally immersed in 70 to 80 cc. of liquid. A tabular summary of the qual. action of 22 alloys in 14 liquids at a temp. of 15° is given. All ordinary alloy steels corrode in water and acids, but to different degrees. The losses of various Cr and Ni steels in acids of different temps. and concns. are given in tables. Ni and Ni steels are resistant to H_2SO_4 and Cr and Cr steels to HNO_3 . Ni also increases the resistance of Cr steels to HCl. Steel with 18% Cr and 8% Ni, called "Staybrite" is more resistant to general corrosion than 12 to 14% Cr steel, and especially so in alternate exposure to sea-water and air. It is austenitic and is not hardened like the Cr "stainless steels" but becomes very ductile when quenched, being more susceptible to cold deformation than the low-C, high-Cr "stainless iron." Staybrite steel has a high impact resistance, and retains its strength well at high temp.; its coeff. of expansion is high and it is non-magnetic. The mech. properties of the stainless steels are given in a brief table. Some illustrations are given of applications of the ductile Staybrite steel. It can be welded by fusion methods, and after cleaning the corrosion resistance at the weld is not impaired. The cost of production is bound to be high, even with a large output, because of the comparative scarcity of Cr.

GEO. F. COMSTOCK

Experience with steel-melting units. I, II. JOHN SONNENFELD. *Foundry* 53, 964-5, 1009-10(1925).—Details of good melting practice for converter and acid elec. steel castings are given. S in converter metal may be kept low by using high-Mn, easy-melting pig and as little coke as possible in the cupola. Scrap for the acid elec. furnace should contain about 0.18% C and 0.20% Mn when melted. If the furnace doors are tightly sealed, N may be absorbed by the steel. The proper use of lime in the slag is explained.

GEO. F. COMSTOCK

Zinc and the problem of corrosion. A. BILLAZ. *Industrie chimique* 12, 202-5, 440-2, 541-3(1925).—A review of the theories of corrosion and of work done on the corrosion of Zn.

A. PAPINEAU-COUTURE

Testing metals for aircraft. N. S. OTEY. *Iron Age* **116**, 1660-4, 1797-1800 (1925).—Uniformity of material is necessary in order that samples may be representative. Piping and segregation are more prevalent in Al alloys than in steel. With mild steel test specimens of $\frac{1}{2}$ in. diam. between shoulders, the tensile stress decreased and the reduction of area increased as the gage length increased from zero to 1 in.; further increase in gage length gave no change in properties. Flattened sections of steel tubing showed less elongation than full-section specimens of the same tubes. Abnormal stresses occur in tensile specimens near the shoulder, and the gage length must be kept further away from the shoulder as the shoulder radius is increased. Tests of different-shaped specimens of duralumin sheet from 0.015 to 0.25 in. thick showed that too short a gage length resulted in low values for elongation and high strength values, while too wide a specimen gave the opposite effect. Another series of tests showed that the deformation in tension increased with the width-thickness ratio. These results are presented in tables and diagrams. Loading should be accomplished with positive and even gripping through some universal socket arrangement, and at the proper speed. Specifications are given for sampling, prep. specimens of sheets, bars, tubes, castings, etc., and for testing methods in tension, bending, impact, etc., with sketches showing all important details. GEO. F. COMSTOCK

Hardness of metals. J. J. CLARK. *Iron and Steel of Canada* **8**, 107-8 (1925).—A simple description of hardness testing by the scratch, Brinell and scleroscope methods; the limitations of each are noted. Abbott's formulas for computing tensile strengths of various steels from Brinell or scleroscope numbers are given. GEO. F. COMSTOCK

Quaternary alloys. N. PARRAVANO. *Bull. soc. chim.* [4], **37**, 1485-521 (1925).—An address expounding the fundamental principles of the method of study of quaternary alloys by means of tetrahedral coordinates showing their application in the study of these alloys to date and indicating lines of further study. A. PAPINEAU-COUTURE

Relation between the color and the chemical composition of alloys. ERNEST PANNAIN. *Rass. min. met. chim.* **63**, 133-6 (1925).—Descriptive, including numerous examples. The subject combines a utilitarian and a theoretical importance. C. C. DAVIS

Effect of cold-working and annealing on some physical properties of copper, aluminium and their alloys. TSUTOMU MATSUDA. *Sci. Repts. Tôhoku Imp. Univ.* **14**, 343-76 (1925).—The effects of rolling, drawing and twisting at ordinary temp. and of subsequent low-temp. annealing on Cu, bronze, brass, Al, duralumin, etc. were studied by tensile tests and measurements of hardness, elec. resistance and expansion. Cold rolling increased the tensile strength and decreased the elongation, more in a transverse than in a longitudinal specimen. Low-temp. annealing removed all differences. The elec. resistance was increased by cold-rolling, similarly in transverse and longitudinal specimens. Cold-drawing and twisting gave similar results. The increased resistance is not due to more regular orientation of the crystals, or to the formation of minute cracks, but may be due to the straining of the space lattice. When cold-rolled plates or cold-drawn rods were heated, abnormalities in the rate of change of resistance occurred around 200° and around 320°. The latter was the temp. of recrystn. and the former marked the beginning of strain-release and was accompanied by slight changes in tensile properties but not in microstructure. Cold working has been found to cause a small decrease in density. Cold-worked specimens were heated in a tube furnace and changes of length up to 500° were compared with similar changes for annealed specimens, the results being shown by curves. Two points of abnormal change were found, at about the same temps. as the points noted above for elec. resistance and they were explained in the same way. Longitudinal specimens showed abnormal expansions, and transverse specimens contractions. In the rods the abnormal change in length began at a lower temp. and was much greater, the difference being due to internal stress. It is concluded that strain produced in the space lattice by cold working contributes to variation in elec. resistance and length. GEO. F. COMSTOCK

Mechanical tests at high temperatures on a non-ferrous alloy of nickel and chromium. H. J. TAPSELL and J. BRADLEY. *Engineering* **120**, 614-5, 648-9, 746-7 (1925).—A brief review is given of previous investigations of creep or flow of metal at high temp. under small loads. An alloy of about 80% Ni and 20% Cr was tested in the "as-rolled" condition, the results being presented in tables and diagrams. Tensile tests made at the usual speed showed that all properties are well maintained up to about 400°, but drop sharply between 500° and 800°. Creep at high temp. makes the value of the tensile strength depend on the speed of testing. Creep may persist for weeks at a low stress until fracture occurs. Creep was investigated by applying different stresses to different specimens at definite temps. between 500° and 800°, and measuring the elongation each

day with an extensometer. The limiting creep stress was detd. as the highest stress under which a continual elongation did not persist at a const. temp. This varied from about half the tensile strength at 500° to about one-tenth at 800°. Torsion tests were made at the same speed and temps. as the ordinary tensile tests, showing similar changes in strength. The angle of twist, and the Charpy impact resistance showed max. at 200°. The Brinell hardness was detd. at room temp. and correlated with results from the Edwards impact hardness test at room and high temp. The hardness decreased with slight irregularity as the temp. rose to 700°. Fatigue tests with the Haigh machine at zero mean stress showed small variations in fatigue range, which was no lower at 700° than at room temp. Comparing these results with those obtained in similar tests by others on various alloys showed that at 350° the tensile strength of the Ni-Cr alloy was about the same as that of high-Cr steel or high-speed steel, but above 350° the Ni-Cr alloy was stronger. In creep tests the Ni-Cr alloy was superior to all other alloys tested at high temp. under steady loading. In torsion strength above 300° and in impact resistance at all temp. it was superior to alloy steels, but its fatigue range was consistently lower than that of a Ni-Cr steel. GEO. F. COMSTOCK

Variation in elastic properties with chemical composition of alloys. P. CHEVENARD AND A. PORTEVIN. *Compt. rend.* 181, 780-2(1925).—Physical properties, such as hardness, thermoelec. power, resistivity and its temp. coeff., when examd. in a series of alloys as functions of the chem. compn., show different variations according as the alloys are composed of two definite phases or a solid soln. C. and P. have investigated the variations of elastic properties in such series. The modulus of elasticity varies very slightly and uniformly with chem. compn. and is not much affected by the structure, with a possible exception in the Fe-Ni alloys with over 26% Ni at temps. where their transformations are not complete. The thermoelastic coeff. varies practically as a straight line in the Fe-C alloys, but not in series of solid solns. such as Ag-Au, for which the curves are shown. The reduction of area at the elastic limit is considerable for pure Fe, but drops rapidly with C up to about 0.2%, remaining const. in annealed steels with higher C. In quenched steels it is higher, with a mix. at the eutectoid compn. In solid solns. (Ag-Au) it is lower than for the pure metals, small alloy addns. causing a rapid drop. It is concluded that the modulus of elasticity is a mol. property, and cannot be raised, like the elastic limit or hardness, by alloying or treatment. G. F. C.

Sand-cast aluminium-manganese alloys. SAMUEL DANIELS. *Ind. Eng. Chem.* 18, 125-30(1926).—The compn. and characteristics of Al-Mn alloys are discussed. The mech. properties of binary sand-cast Al alloys are not improved by heat treatment. More than 2% Mn increases the shrinkage, the unsoundness and the difficulties in machining. The Mn does not affect the normal resistance of c. p. Al to salt-spray corrosion and probably improves the resistance in ternary and more complex alloys. Al-Mn alloys are less resistant to corrosion by distd. water than to that by salt-spray. Metallographic examn. of the as-cast alloy after addn. of 0.5% Mn showed the presence of tiny blue-gray colonies of a new compd., possibly MnSi. Several tables, curves, and photomicrographs are shown. W. H. BOYNTON

Aircraft castings in aluminium alloys. SAMUEL DANIELS. *Am. Foundrymen's Assoc. Preprint* No. 471, 22 pp.(Oct., 1925); *The Foundry* 53, 1003-6(1925).—The 6 Al alloys used by the U. S. Air Service for castings are described in detail and specifications for the raw materials used are given. The methods for making the hardeners used for introducing Cu, Ni, Fe and Si into the alloys are described. The alloy with 8% Cu is most commonly used, being easy to cast and machine, though low in strength and ductility. The alloy with 10% Cu, 1.25% Fe and 0.25% Mg maintains its strength and hardness well at high temp. It may be strengthened by heat treatment, but has low ductility. The alloy with 2.5% Cu, 1.25% Fe and 0.5% Mg has a better combination of strength and ductility. The alloy with 5% Cu and 1% Si is hard to cast without cracking, but after heat-treatment has excellent strength and ductility. The alloy with 4% Cu and 3% Si is excellent for complicated or difficult castings, but is not easily machined. The alloy with 4% Cu, 2% Ni and 1.5% Mg is used for castings subjected to high temps. and has excellent strength and machinability after heat-treatment. The structures are illustrated by excellent photomicrographs. Specifications for castings and test-bars are given. GEO. F. COMSTOCK

The behavior of inhomogeneous aluminium castings on cold rolling. E. SEIDL AND E. SCHIEBOLD. *Z. Metallkunde* 17, 221-6, 320-8, 365-8(1925).—From commercial bars of Al (10 × 10 × 125 cm.) contg. 0.2% Si and 0.3% Fe small cubical samples were cut and were studied microscopically, mechanically and by means of X-rays. The castings showed a radial structure of long fibers extending from the outside towards the center, while the core consisted of a conglomerate of rounded grains. Samples

were taken from the outside (zone of nuclei), from the center and from the fibrous material in between. These three zones showed distinct differences on etching and also differed in Brinell hardness. In the center the (av.) hardness was 16.5, on the outside 20 and in the fibrous structure 18.8. Laue diagrams of these 3 zones indicated that in the outer zone considerable stresses existed as shown by the pronounced asterism of the interference points. In the fibrous zone and in the interior the stresses have largely been equalized during cooling and as a result the tendency towards asterism is much less. Annealing destroyed the phenomenon of asterism. The effect of increasing degrees of cold rolling (25, 70 and 99% deformation) on pieces cut in the direction of the fibers, crosswise and vertically, is illustrated by a series of interesting Laue diagrams. The rods cut lengthwise reach the "rolling texture" most readily as proved by the very symmetrical arrangement of the asterism in the Laue diagram while those cut vertically show the least symmetrical arrangement. A detailed macroscopic study was made, illustrated by numerous sketches and photographs, of the deformation of the castings when subjected progressively to cold rolling. H. S. v. K.

The economy in the electric arc welding of ingot iron. KARL MELLER. *Siemens-Z.* 5, 457-64(1925).—The recent increasing application of the elec. arc for welding of ingot iron is merely due to a better economy in the working method. This welding is at present only undertaken with metal electrodes, directly molten into the seams. Data in regard to technology and efficiency are given in detail, followed by a series of diagrams. For the comparison of expenses with autogenous welding an example is given in the welding of an oil tank, made from 8-mm. plate, 2 m. high and 1.3 m. diam. The elec. arc welding showed an actual saving of 50.6%. D. THUESSEN

Cooling fractures in journal brasses. R. R. CLARKE. *Metal Ind.* (N. Y.) 23, 448(1925).—Cracks in journal brass castings are not always due to cooling strains, shrinkage, or improper gating. Pressure of steam from the mold is a frequent cause of cracking while the metal is plastic and weak. A thin facing of hard impervious sand to keep the pressure of gas from the mold away from the casting prevented cracking as well as mold erosion. GEO. F. COMSTOCK

Treating ores. D. C. HARE. Brit. 234,524, May 26, 1924. Ores are roasted to form sol. compds. and volatilized substances are conveyed from the roasting furnace for recovery of their values. The residue is subjected to leaching. NaCl and S, the latter if not present in sufficient quantity in the ore itself, are used in the roasting. CaCl₂, MnO₂, vanadic acid or Ce nitrate also may be added as may also Cl (activated by ultra-violet rays). Treatment of Pb, Zn, Cu, Ag and Au ores is referred to. With Au, C is also added to the charge to prevent the formation of S chloride and AuCl₃ is then produced by the action of CCl₄ which is formed. An app. is described.

Treating iron ores. MASCHINENBAU-ANSTALT HUMBOLDT. Brit. 234,377, Nov. 11, 1924. Low-grade Fe ore contg. a large proportion of SiO₂ is roasted at a temp. insufficient to cause sintering and quenched in H₂O. The product is subjected to rub-

bing to sep. ore particles from SiO_2 and then to washing and magnetic and mech. sepn.

Treating sulfide ores. F. KRUPP AKT.-GES. GRUSONWERK. Brit. 234,826, May 30, 1924. Sulfidic ores or similar materials contg. volatilizable metals such as Zn, Pb, Sn, Bi, As and Sb are decomposed, in one operation at a high temp. without previous roasting, to effect volatilization of the metals and combination of the S with the residue. The oxidation of the metallic vapors may then be effected immediately or as a sep. operation. Raw ore is mixed with coke or other reducing material to maintain a strong reducing atm. in the material itself and a neutral atm. adjacent the particles of material so that oxidation of S is avoided. Temps. of $1250\text{--}1400^\circ$ are suitable. Alk. compds. may be added to fix the S; and refractory material such as Al_2O_3 , SiO_2 or limestone may be added to prevent liquefaction of the charge.

Briquetting ores. A. CARLSON. Brit. 233,731, May 10, 1924. "Purple ore," burnt pyrites or other material contg. Fe_2O_3 is mixed with 2-3% CaO and pressed into briquets which are hardened by steam.

Refining copper-nickel mat. R. L. PEEK and T. F. TORELL. U. S. 1,569,137, Jan. 12. In utilizing bessemerized Cu-Ni mat, Cu is sepd. from Cu-Ni sulfate solns. by cementation upon an excess of the mat, the greater part of the Cu is removed from the partially exhausted mat and from the residue there is produced Cu-Ni sulfate soln. for treatment of a further quantity of bessemerized mat.

Gas-fired furnace for blast-furnace boilers, Cowper apparatus, etc. ASKANIA-WERKE AKT.-GES. VORM. CENTRALWERKSTATT-DESSAU UND C. BAMBERG-FRIEDENAU. Brit. 234,791, May 31, 1924.

Thermostatic control device for gas supply to furnaces for melting metals, etc. C. F. H. BOHNHARDT. U. S. 1,569,312, Jan. 12.

Furnace for melting brass, type metal, etc. W. H. CHENOWITH and G. C. SCHIMPF. U. S. 1,569,314, Jan. 12.

Hardening copper. L. NEMITOF. U. S. 1,569,130, Jan. 12. Cu heated to bright redness is embedded in a mixt. moistened with mineral distillate oil or other hydrocarbon material and comprising sand or similar siliceous substance and ground bone or other material contg. Ca phosphate.

Producing aluminium, copper or other metals in powdered form. E. J. HALL. U. S. 1,569,484, Jan. 12. While disintegrating metal in a ball mill or the like it is kept covered with "varnoline" (a petroleum distillate) or with a protective lubricating liquid of similar properties with respect to facility of sepn. by evapn.

Granulating metals. HARTSTOFF-METALL AKT.-GES. (HAMETAG). Brit. 233,720, May 7, 1924. Molten metal is fed into the path of a rapidly rotating beater and the subdivided metal thus formed is projected into tetralin, paraffin or other inert material. The beater may be surrounded by CO_2 or other inert gas.

Magnetic silicon iron. V. B. BROWNE. U. S. 1,570,229, Jan. 19. A Si Fe with a sufficient Si content to adapt it for use as a magnetic alloy and a C content of not over 0.03% is made by reducing the C in refined Fe by making additions of Fe ore to the bath until no further reduction of C is effected by these additions, then causing air or other oxidizing gas to permeate the bath until substantially all the remaining C is removed and making the necessary Si additions to the metal.

Decarburizing iron or other metals. P. J. MARTIN and G. F. BERTELS. Brit. 234,434, May 23, 1924. In decarburizing Fe, Cr, Mo, U, V, etc., by CO_2 the materials are heat-treated in the presence of metallic oxides capable of transforming the CO formed during the decarburizing process into CO_2 . Oxides of Sn or Zn may be used, or ferric oxides, mixed with inert materials, e. g., SiO_2 , Al_2O_3 or lime and the CO_2 used may be pure or may contain N or other inert gases.

Casting iron. MEIER and WEICHEL. Brit. 234,106, May 13, 1924. To insure the solidification of Fe in a finely divided state, the rate of cooling the casting is varied according to the Si and C content. Fe contg. 3% Si may be cast in a chill. If white Fe or pearlite is found in the casting it is heated for a short time to convert them into ferrite.

Degassing and deoxidizing steel. S. PEACOCK and N. E. COOK. U. S. 1,570,176, Jan. 19. Molten Fe or steel is treated with anhyd. tri-Na aluminate, forming compds. with any eutectoids present that melt in the metal and liberating any compds. of O and C that are associated with the eutectoids.

Annealing sheet steel. G. H. COLE. U. S. 1,569,355, Jan. 12. Sheets of magnetic Si steel alloy are heated to a temp. not above 700° in an atm. contg. C in about the same proportion to N as in air, and then cooled.

Furnace for annealing sheet steel, etc. G. H. COLE. U. S. 1,569,356, Jan. 12.

Furnace for annealing metal plates and sheets. E. WIRZ. U. S. 1,569,444, Jan. 12.

Tellurium for refining or modifying metals. A. I. Pocock, C. T. CALVER and W. H. WATKINS. Brit. 234,547, Feb. 27, 1924. In treating Al, Al-Cu alloys or other metals (excepting Pb and alloys contg Pb) Te is introduced beneath the surface of the molten metal in powd. form or alloyed with other metals such as Cd, Ca, Cr, Cu, Au, Fe, Mg, Mn, Ni or Zn or, in some cases, Si or W. The added material may be enclosed in metal foil or sheet.

Crucibles for melting metals. A. J. JACKMAN. U. S. 1,570,064, Jan. 19. Crucibles for melting steel or other metals with accompanying slag formation comprise a graphitic body portion adapted to contact with the bulk of the metal and a portion of chromite, sillimanite, zirconia, spinel, zircon or other more resistant material adapted to contact with the slag and withstand its action.

Treating lead and other metals with phosphorus. AMERICAN MACHINE AND FOUNDRY CO. Brit. 234,618, June 19, 1924. Pb-P alloy is made by heating Pb with P at 650° in an inert gas and this alloy is used for treating additional Pb or other metals.

Magnesium. B. E. F. RHODIN. Brit. 234,074, May 13, 1924. See U. S. 1,539,955 (C. A. 19, 2184).

Alloy steel. J. I. MEE. U. S. 1,569,996, Jan. 19. An alloy adapted for making hard bearings, burglar-proof vaults, etc., is formed from W 65-68, V 2, C 4, Cr 2-5, S 0-1, Cu 3-5, Ir 0-3, Co 0-4 and pig Fe 14-18%.

Alloy for pen points. M. M. GOLDSMITH. U. S. 1,569,921, Jan. 19. Os 65-85 is alloyed with Ru 10-20 and Ni 3-10 parts.

Welding copper with zinc, tin, etc. ELECTRO-METALLURGICAL CO. Brit. 233,395, May 26, 1924. A welding rod or the like (for welding Cu or Cu alloys to Zn, Sn, etc.) is formed of an alloy of Cu with Si 0.5 or less (in no case over 4%) or with Mn 0.5-1.0 and Si 0.3-0.8%. An alloy of Cu with over 5% Si may be used for filling up holes in castings.

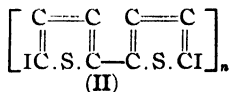

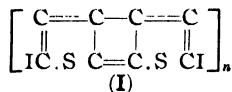

Pressure-molding of heavy fusible metals from crucibles. E. PETERSSON. Swed. 59,978, Dec. 8, 1925. A tube of refractory material, for instance SiO₂ glass, is built within the wall of the crucible communicating with the metal bath through a hole near the bottom of the crucible and provided with a nozzle for connecting it to the mold.

Ingot mold. E. GATHMANN. U. S. 1,570,473, Jan. 19.

10--ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Some substances analogous to graphite. R. CIUSA. *Gazz. chim. ital.* 55, 385-9.—Ciamician and Ciusa (C. A. 15, 2838) showed that C₆, C₈S, C₄NH can exist. Such compds. would tend to polymerize giving (C₆)_n, (C₄S)_n, (C₄NH)_n and (C₄O)_n, *i. e.*, common graphite and graphite of thiophene, pyrrole and furan, resp. Pauly and Waltzinger (C. A. 8, 127) obtained somewhat similar products. C. heated indole at 150° *in vacuo* and obtained (2C₄NH)_n, which is an intermediate compd in the prepn. of graphite of pyrrole. Tetraiodothiophene (Paolini, C. A. 10, 1972) heated 2-3 hours, *in vacuo* loses 3 I atoms at 340°, giving I or II. The I was not all eliminated even at 490° but

at 450° in a current of CO₂ (free from O₂) all I was removed. The graphite (C₄S)_n thus obtained is another sulfide of C to be added to those known: CS, CS₂, C₂S₃, C₃S₂, C₆S₂. Furan reacts easily with Hg(OAc)₂ giving the tetraacetate. The latter was converted into the chloride and this with KI gave tetraiodofuran (III), m. 145°. Heated in the sealed tube and then in a current of CO₂ III loses all of its I and some O. The pure graphite of furan was not obtained. Hexaiodobenzene heated in the sealed tube to 400° gives a product contg. 46.33% I. This product heated to redness in CO₂ lost all I and gave the graphite of benzene, which is quite similar to ordinary graphite. The conversion of ordinary C into graphite requires very high temps. while the temps. used here are relatively low.

E. J. WITZEMANN

Oxidation of ethyl ether to oxalic acid in presence of uranyl nitrate. S. W. ROWELL and A. S. RUSSELL. *J. Chem. Soc.* 127, 2900-2(1925).—Et₂O (60 g.), 60 g. UO₂(NO₃)₂ and 20-60 g. H₂O, exposed to bright sunlight for 24 hrs., give up to 12 g. of UO₂C₂O₄.

2H₂O. In certain expts. a light yellow basic oxalate, U(OH)₄·UO₂C₂O₄·2H₂O(?), was formed. When UO₂(NO₃)₂ in Et₂O is neutralized so that a ppt. is just not formed and exposed to sunlight for a few hrs., there results a black or greenish black slimy ppt. of U(OH)₄. A suggested mechanism of the above reaction is given. C. J. W.

Hydroxy and ethoxy mercaptans and their condensation products. C. A. ROJAHN AND GUSTAV LEMME. *Arch. Pharm.* **263**, 612–24 (1925).—In a study of various reactions looking to the prepn. of hydroxy and ethoxy mercaptans and certain related products of possible hypnotic nature, the following compds. were prepd. and characterized. 1,3-Bisethylmercapto-2-propanone, CO(CH₂SEt)₂, from CO(CH₂Cl)₂ and EtSH, b₁₆ 117–21° (semicarbazone, C₈H₁₇N₃S₂O, m. 98–9°; dimethiodide, C₉H₂₀S₂I₂O, m. 182°). 1,2,2,3-Tetrakisethylmercapto propane, C(SEt)₂(CH₂SEt)₂, b₁₆ 51–3°. γ -Ethoxypropyl mercaptan, EtOCH₂CH₂CH₂SH, from EtOCH₂CH₂CH₂Br and KSH, b₂₀ 52–4°. γ -Ethoxypropyl benzyl sulfide, EtO(CH₂)₃SCH₂Ph, b₁₉ 161°; γ -ethoxypropyl benzyl sulfone, EtO(CH₂)₃SO₂CH₂Ph, m. 45–6°. Acetone di- $[\gamma$ -ethoxypropyl] mercaptole, Me₂C(SCH₂CH₂CH₂OEt)₂, from AcMe and EtO(CH₂)₃SH by the action of ZnCl₂; methyl ethyl ketone di- $[\gamma$ -ethoxypropyl] mercaptole, MeEtC(SCH₂CH₂CH₂OEt)₂. γ -Hydroxypropyl mercaptan, HOCH₂CH₂CH₂SH, from Cl(CH₂)₃OH and NaSH, b₁₆ 85–90° (dibenzozate, C₁₇H₁₆SO₃, oil), yields on boiling with fuming HCl dihydrodimethylenglycol mono- $[\gamma$ -chloropropyl] ether, HS(CH₂)₃S(CH₂)₃Cl, oil (benzoate C₁₃H₁₇OS₂Cl, oil); γ -hydroxypropyl disulfide, S₂(CH₂CH₂CH₂OH)₂, (dibenzozate C₂₀H₂S₂O₄, oil); γ -hydroxypropyl benzyl sulfide, HO(CH₂)₃SCH₂Ph, b₂₀ 185–8° (benzoate C₁₇H₁₆SO₃, oil); acetone di- $[\gamma$ -hydroxypropyl] mercaptole, Me₂C(SCH₂CH₂CH₂OH)₂, (dibenzozate C₃H₂S₂O₄, oil); methyl ethyl ketone di- $[\gamma$ -hydroxypropyl] mercaptole, MeEtC(SCH₂CH₂CH₂OH)₂, oil, (dibenzozate C₂₄H₃₀S₂O₄, oil); benzaldehyde di- $[\gamma$ -hydroxypropyl] mercaptal, PhHC(SCH₂CH₂CH₂OH)₂, oil (dibenzozate C₂₇H₂₈S₂O₄, oil). Diacetate of β -hydroxyethyl mercaptan, AcOCH₂CH₂SAC, b₂₅ 118–20°; β -ethoxyethyl mercaptan, EtOCH₂CH₂SH, b₁₅ 37–40°; β , β' -di- $[\beta$ -ethoxyethyl] disulfide, S₂(CH₂CH₂OEt)₂, b₁₅ 150–2°; β -ethoxyethyl benzyl sulfide, EtOCH₂CH₂SCH₂Ph, b₁₆ 146°; methyl ethyl ketone di- $[\beta$ -ethoxyethyl] mercaptole, MeEtC(SCH₂CH₂OEt)₂.

W. O. E.

Addition of alkali alcoholate to acid esters. I. ADICKES. *Ber.* **58B**, 1992–9 (1925).—The formation of alkali alcoholate addn compds. with acid esters as intermediate products has been assumed in a no. of reactions. In all these cases the basis for such an assumption has been the addn. products of benzoates described by Claisen (*Ber.* **20**, 651 (1887)), the existence of which, however, as shown below, can as a matter of fact not be proved at all. When alc.-free NaOEt in dry Et₂O suspension is treated with somewhat less than 1 mol. (CO₂Et)₂, much heat is evolved and 1 equiv. NaOEt dissolves; after a short time the mixt. is rapidly filtered and the soln. evapd. *in vacuo*, protected from moisture. The solid product (I) so obtained has the compn. (CO₂Et)₂·NaOEt, and is very hygroscopic and unstable. It yields EtO₂CCO₂Na, not by splitting off Et₂O but as the result of the hydrolytic action of traces of moisture, even in a H₂SO₄ desiccator, when allowed to stand a long time, and is no longer sol. in Et₂O. It decomp. about 115° with formation of CO and Et·CO₂; the residue reacts strongly alk. and contains much (CO₂H)₂. It undergoes a similar decompn. in hot xylene. In Et₂O it at once gives with dry CO₂ a gelatinous ppt. of NaEtCO₃. With H₂O it gives (CO₂Na)₂ and (CO₂Et)₂ while with acids free from H₂O it yields (CO₂Et)₂ and the Na salt of the acid. With CS₂ it yields EtOCS₂Na. No hemi-ortho-oxalate can be obtained with EtBr or Me₂SO₄. The addn. product of NaOMe to (CO₂Et)₂ has the compn. C₇H₁₅O₆Na, gives with H₂O an equimol. mixt. of EtO₂CCO₂Na and MeO₂CCO₂Na and in Et₂O with dry CO₂ mixts. of NaMeCO₃ + NaEtCO₃ and EtO₂CCO₂Me + (CO₂Et)₂. The addn. product, C₆H₁₁O₆Na, of NaOEt to (CO₂Me)₂ behaves in the same way. There is therefore no evidence against the formulation EtO₂CC(OEt)₂ONa for I; that no hemi-ortho-oxalate can be obtained from it may be explained by assuming an equil., EtO₂CC(OEt)₂ONa \rightleftharpoons (CO₂Et)₂ + NaOEt, which, even if shifted almost completely to the left, would prevent the formation of the hemi-ortho-oxalate on account of the much greater reaction velocity between the NaOEt and the EtBr. Not more than 1 mol. NaOEt can be added to (CO₂Et)₂. The KOEt addn. product is markedly less stable than I; it reacts vigorously with H₂O with partial destruction of the (CO₂H)₂, and even on slower decompn. by moisture it gives no EtO₂CCO₂K. The properties of these addn. products are entirely different from those of Claisen's compds. The substance obtained from BzOEt and NaOEt on the H₂O bath, when washed with Et₂O, contains 31.6–26.1% Na, depending on the length of heating, and that it is really a mixt. of NaOEt and gelatinously pptd. NaOBz was confirmed by detg. the amt. of Na present as NaOEt by titration; calcn. then showed that the rest of the Na could be present only as NaOBz. That the substances obtained by C. from BzOMe + PhCH₂ONa,

$\text{BzOCH}_2\text{Ph} + \text{NaOEt}$ and $\text{BzH} + \text{NaOEt}$ consist of NaOBz , often mixed with some Na alcoholate, was found by A. in a series of expts. carried out before he was aware of the work of Tishchenko (C. A. 7, 777), who reached the same conclusions. C. A. R.

Transformation induced by solar light in the presence of uranic compounds. MME. J. ALOY AND A. VALDIGUIÉ. *Bull. soc. chim.* 37, 1135-40(1925); cf. C. A. 16, 1905; 17, 2705.—When various org. compds. are mixed with 5% U salt solns. in glass tubes and exposed to sunlight for a few hrs., the ease with which a violet ppt. of $\text{U}_3\text{O}_8 \cdot 2\text{H}_2\text{O}$ is formed serves as a standard of comparison of their relative stability. The discoloration of methylene blue is another test of reducing power. Substances with satd. C-C linkages in general were most resistant to catalytic decompn. by U salts. Aldehydes gave positive results, but ketones were resistant to change. Ethylenic compds. gave abundant violet ppts. This evidence supplements knowledge of stability gained from chem. behavior. H. R. MOORE

The higher methyl ketones. G. T. MORGAN AND EUSEBIUS HOLMES. *J. Soc. Chem. Ind.* 44, 491-2T(1925); cf. C. A. 19, 2807.—Behenic acid (I), m. 83°, was prep'd. by reduction of erucic acid with H in the presence of colloidal Pd. Distn. of the mixed Ba salts of I and AcOH yielded *Me n-heneicosyl ketone* (II), m. 66.5°. Oxidation of II with $\text{Na}_2\text{Cr}_2\text{O}_7$ and H_2SO_4 yielded *heneicosic acid* (III), m. 74°; Me ester m. 49.5°. Distn. of the Ba salt of III with $(\text{AcO})_2\text{Ba}$ yielded *Me eicosyl ketone*, m. 63.5°. T. S. CARSWELL

The crossed Cannizzaro reaction. III. CHUSETSU ENDOH. *Rec. trav. chim.* 44, 866-75(1925).—(In German.) Cannizzaro's reaction takes place thus: $2\text{RCHO} + \text{HOH} \rightarrow \text{RCH}_2\text{OH} + \text{RCO}_2\text{H}$. Nord (C. A. 14, 3677; 17, 1526; *Beitr. Physiol.* 2, 301(1924); (and Nakai) C. A. 19, 2807) have described a mixed or crossed Cannizzaro reaction involving 2 aldehydes: $\text{R}'\text{CHO} + \text{R}''\text{CHO} + \text{HOH} \rightarrow \text{R}'\text{CH}_2\text{OH} + \text{R}''\text{CO}_2\text{H}$ (or $\text{R}''\text{CH}_2\text{OH} + \text{R}'\text{CO}_2\text{H}$). The existing literature and views on the significance of this reaction in chemistry and biology are carefully reviewed. The aldehydes may also be considered as adding to the alcoholate used: $\text{R}'\text{CHO} + \text{R}'\text{OM} \rightarrow \text{R}'\text{CH}(\text{OM})\text{OR}^\circ$ (I); $\text{R}''\text{CHO}$ then adds to I, giving $\text{R}'\text{CH}(\text{OR}^\circ)\text{OCHR}''(\text{OM})$, which decomps. giving the mixed ether $\text{R}'\text{CH}_2\text{OC}(\text{O})\text{R}''$ and $\text{R}'\text{OM}$. 7 pairs of aldehydes have been investigated for their capacity to undergo this reaction, giving a mixed ether. In this paper the action of AcH with an unsatd. aldehyde ($\text{PhCH}:\text{CHCHO}$ (II)) was investigated. Tishchenko and Gushov (*J. Russ.-Phys. Chem. Ges.* 38, 517(1906)) and Pauly, Schmidt and Böhme (C. A. 19, 265) obtained unsatisfactory results in this condensation with Al alcoholate but E. found that the reaction goes smoothly, giving cinnamyl acetate (III) and *Et cinnamate* (IV). The formation of styracin led to the study of this reaction for the prep'n. of cinnamic alc. (V). 3.0 g. powd. $\text{Al}(\text{OEt})_3$ was added to 33 g. II in 33 cc. cold abs. Et_2O and after standing 1 day at room temp. the mixt. was warmed some days on the H_2O bath, poured into satd. NaCl, then treated with the calcd. amt. of HCl required to convert the $\text{Al}(\text{OH})_3$ into AlCl_3 and repeatedly extd. with Et_2O ; the Et_2O soln. was washed with NaHCO_3 , dried several days over Na_2SO_4 and fractionated *in vacuo*: (1) b_{10} 131-40°, 14.6 g.; (2) b_{10-11} 145-200°, 8 g. After refractionating again the portion b_{10} 138.5-41.5° was seeded in vain with V. 15 g. of this fraction in 100 cc. abs. Et_2O was treated with 30 g. powd. fused CaCl_2 . After 24 hrs. the ppt. was filtered off, washed with Et_2O and decompd. with H_2O ; the V was extd. with Et_2O , etc., and 0.5 g. III, m. 30°, was obtained. The filtrate from the CaCl_2 ppt. was fractionated after evapg. the Et_2O and found to be a mixt. of IV and V. Details of other preps. also are given. A 41% yield of cryst. V was obtained. 66 g. II + 22 g. pure dry AcH with 50 cc. Et_2O and 15% $\text{Al}(\text{OEt})_3$ were heated 3.5-5 days on the H_2O bath. When this was worked up a mixt. of III and IV was obtained. III, which was a new compd., was prep'd. from V and Ac_2O , b_{12} 142-4°. The CaCl_2 compd. with V, $\text{CaCl}_2 \cdot 1.5\text{PhCH}:\text{CHCH}_2\text{OH}$, m. 157°, was prep'd. from V in abs. Et_2O with powd. fused CaCl_2 and filtered off after standing 24 hrs. E. J. WITZEMANN

Observations on the Claisen reaction. G. T. MORGAN AND EUSEBIUS HOLMES. *J. Chem. Soc.* 127, 2891-6(1925); cf. C. A. 19, 1558.—The fatty acid was converted into its Ba salt, distd. with 3 mol. proportions of $\text{Ba}(\text{AcO})_2$, the crude product purified and subjected to the Claisen condensation with Na and AcOEt; under these conditions the ketones $\text{C}_n\text{H}_{2n-1}\text{Ac}$ (where n varies from 7 to 19) give normal reactions and a satisfactory yield of the diketone. The % below are the yields as the Cu salt. Octoylacetone, b_5 118°, $b_{7\text{HS}}$ 248°; Cu salt, pale blue, m. 118° (41-8%). Nonoylacetone, b_{11} 150°; Cu salt, m. 115.5° (69%). Undecoylacetone, m. 28°; Cu salt, m. 112° (70%). Dodecylacetone, m. 31-2°; Cu salt, m. 112.5° (50%). Tridecylacetone, m. 35°, gives a red color with FeCl_3 only on warming; Cu salt, m. 111° (64%). Tetradecylacetone, m. 39°; Cu salt, m. 112° (52%). Pentadecylacetone, m. 42°; Cu salt, m. 111° (35%).

Hexadecoylacetone, m. 49°; *Cu salt*, m. 112° (34%). *Heptadecoylacetone*, m. 51°; *Cu salt*, m. 112° (27%). *Octadecoylacetone*, m. 52.5°; *Cu salt*, m. 113° (55%). *Nona-decylacetone*, m. 55°; *Cu salt*, m. 112.5° (32%). *Eicosanoylacetone*, m. 57°; *Cu salt*, m. 114° (28.4%). All the Cu salts are blue, but the color becomes less pronounced as the series is ascended.

C. J. WESR

Hydrogenation of aldehydes and ketones in the presence of platinum blacks. M. FAILLEBIN. *Ann. chim.* 4, 156-82, 410-96(1925).—A more active Pt black is obtained from K_2PtCl_6 than from H_2PtCl_6 . Pt blacks contg. known amts. of Fe, Al and SiO_2 were prepared by reduction of mixts. of the chlorides with HCHO and NaOH. A slow reduction and a low temp. (-5°) is necessary for the most active catalysts. The catalyst is washed free from salts by decantation and by drying either *in vacuo* or by using abs. EtOH and Et_2O . Acetone with the pure Pt gives propane, while the Pt contg. Fe gives iso-PrOH. The Pt contg. SiO_2 gives propane. The velocity of hydrogenation is much slower than with the first two catalysts. With $MeCOEt$ there is the same difference between the pure Pt and that contg. Fe; pure Pt gives butane, while Pt contg. Fe gives sec-BuOH. Pure Pt gives, with $MeCOPr$, pentane, while the Pt-Fe gives pentanol. The hydrogenation of $AcCH_2CO_2Et$ in the absence of a solvent has been studied in the presence of pure Pt, Pt-Fe, Pt- SiO_2 and Pt- Al_2O_3 . Alc., ether and normal hexane have been used as solvents. With $AcCH_2CO_2Et$, the differences between the actions of pure Pt and that of the Pt contg. Fe is most marked. The action of Pt contg. Al_2O_3 is entirely comparable with that of Pt contg. Fe; Pt contg. SiO_2 has essentially the same effect as pure Pt. With pure Pt, $PrCO_2Et$ (I) is obtained. Pt containing Fe gives $MeCH(OH)CH_2CO_2Et$ (II); Pt contg. Al_2O_3 gives some I and a small amt. of II. Pt containing SiO_2 gives a result intermediate between that of pure Pt and Pt contg. Fe, the products being I and II. The hydrogenation of $AcCH_2CO_2Et$ in ether gives the following results: pure Pt, I; Pt contg. Fe, II. In normal hexane, $AcCH_2CO_2Et$ gives with pure Pt mainly I; Pt and Fe, II. In alc., pure Pt gives I and II. With Pt contg. Fe, *o*- $MeOC_6H_4CH_2CH_2COMe$ (III) in $AcOEt$ and $AcOH$ is hydrogenated to *o*-methoxy-4-phenyl-2-butanol, $MeOC_6H_4CH_2CH_2CH(OH)CH_3$, liquid with a strong odor resembling the poppy, b_{13} 144°, $b_{0.5}$ 90-1°, n_D^{18} 1.5245, d_{18} 1.044. Its benzoate, b_9 212°, $b_{0.33}$ 163°, d_{18} 1.0995, n_D^{18} 1.5500. With pure Pt, III gives a variety of substances depending in part upon the proportion of the reacting substances used, among them being cyclohexylbutane, b_{781} 176-7°, $n_D^{17.5}$ 1.4438, $d_{17.5}$ 0.8043. A detailed study of the other substances prepd. is given, among which are 4-cyclohexyl-2-butanol and 4-[2-methoxycyclohexyl]-2-butanol. The acetate of the latter, b_9 133.5-4.0°, $n_D^{21.5}$ 1.4540, $d_{21.5}$ 0.972. *p*- $MeOC_6H_4CH_2CH_2COMe$, prepared from anisalacetone in the presence of Pt contg. Fe, liquid of slight odor, m. 9°. With the same catalyst, *p*- $MeOC_6H_4CH_2CH_2COMe$ in $AcOEt$ or $AcOH$ was hydrogenated to 4-*p*-methoxyphenyl-2-butanol, $b_{0.5}$ 107°, n_D^{16} 1.5249, d_{16} 1.042. From this, two esters were prepd.: the acetate, by heating the alc. with Ac_2O at 140° for 2 hrs., $b_{0.25}$ 104°, $b_{0.16}$ 99°, b_{14} 160°, n_D^{21} 1.4956, d_{21} 1.0322; and the benzoate, from the alc. and $BzCl$, $b_{0.33}$ 172°, n_D^{28} 1.5427, d_{28} 1.080. With a pure Pt catalyst from *p*-methoxybenzylacetone, several products are possible: *p*- $MeOC_6H_4CH_2CH_2CH(OH)Me$, $b_{0.33}$ 107°, *p*- $MeOC_6H_4Bu$, b_{19} 120°, $b_{0.25}$ 55°, *p*- $MeOC_6H_{10}CH_2CH_2CH(OH)Me$, $b_{0.25}$ 84°, *p*- $MeOC_6H_{10}Bu$, $b_{0.25}$ 47°; $C_6H_{11}CH_2CH_2CH(OH)Me$, b_{14} 112°, and $C_6H_{11}Bu$, b. 176-7°. In the presence of Pt-Fe, and $AcOEt$ as solvent, veratrylacetone has been hydrogenated to 4-[3,4-methoxyphenyl]-2-butanol, $b_{0.2}$ 125°, n_D^{18} 1.5316, d_{18} 1.095; its acetate $b_{0.33}$ 132°, n_D^{18} 1.509, d_{18} 1.086. Piperonylacetone has been hydrogenated (with Pt-Fe) to *p*-[3,4-methylenedioxyphenyl]-2-butanol; b_{10} 168°, n_D^{21} 1.5340, d_{21} 1.146; its acetate and benzoate have been prepd. Pure Pt has been used in this connection but its products have not been identified. Acetone, quinone, piperonalacetone have been hydrogenated. With aldehydes, the difference between Pt and Pt-Fe is very marked. iso-BuCHO, enanthal, BzH, *p*- $MeOC_6H_4CHO$ have been hydrogenated with the above two catalysts.

J. H. PERRY

Preparation and specific gravity of mesityl oxide. C. A. YLLNER. *Svensk Kem. Tids.* 37, 227-9(1925).—Forty cc. acetone is stratified over 25 cc. concd. H_2SO_4 and carefully mixed to a completely homogeneous fluid. When deep red it is poured into ice water. The dark orange emulsion is extd. with Et_2O and washed with soda soln. The Et_2O is distd. and the residue fractionally distd. at 125-35°, treated with alc. KOH and redistd. at 128-31°. Yield, 25%; d_4 0.8634.

A. R. ROSE

The reaction of organomagnesium compounds on nitriles. Chloroacetonitrile. L. MATHUS. *Bull. soc. chim. Belg.* 34, 285-9(1925).— CH_3ClCN with $PhMgBr$ gives

95% of undistillable pitch, small amts. of Ph_3 , PhCOCH_2OH and PhCOCH_2Cl being isolated by extn. and distn.

WM. B. PLUMMER

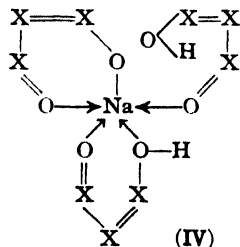

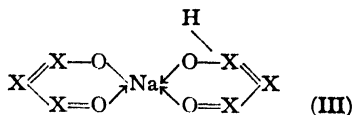

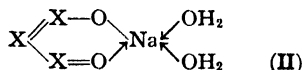

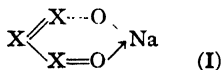

Condensation of the sodium derivatives of trimethyleneglycol and glycerol. ARTHUR FAIRBOURNE AND G. E. FOSTER. *J. Chem. Soc.* **127**, 2759-64 (1925); cf. *C. A.* **15**, 3079.— Na (1.14 g.) in 40 cc. $\text{HO}(\text{CH}_2)_3\text{OH}$ (I), treated with 10.2 g. $2,4\text{-(O}_2\text{N)}_2\text{-C}_6\text{H}_3\text{Cl}$ in 30 cc. I and heated until soln. was complete, gave 6 g. *trimethyleneglycol 2,4-dinitrophenyl ether*, m. 52° (*Ac deriv.*, m. 85° ; *Bz deriv.*, m. 95°) and 0.5 g. of the *bis-ether*, m. 180° . Either the mono- or di- Na deriv. of $\text{C}_3\text{H}_6(\text{OH})_3$, treated with an equimol amt. of $p\text{-MeC}_6\text{H}_4\text{SO}_2\text{Cl}$ in Et_2O or C_6H_6 , gives *glyceryl tri-p-toluenesulfonate*, m. 103° , mol. wt. in freezing C_6H_6 , 564; the corresponding *tribenzenesulfonate*, m. 80° . The di- Na deriv. of $\text{C}_3\text{H}_6(\text{OH})_3$ and BzCl give the tri-*Bz* deriv., m. 72° after crystn from ligroin, m. 75° after crystn from EtOH . The mono- Na deriv. and $p\text{-O}_2\text{NC}_6\text{H}_4\text{-COCl}$ yield the mono-deriv., m. 107° . *Isopropylidene ether of glycerol 3,5-dinitrobenzoate*, m. 85° (80% yield); heated with 0.5 *N* HCl at $70\text{--}80^\circ$ for 1 hr., it gives 70% of *glycerol α -mono-3,5-dinitrobenzoate*, m. 118° , also obtained from the mono- Na deriv. and $3,5\text{-(O}_2\text{N)}_2\text{C}_6\text{H}_3\text{COCl}$ in Et_2O .

C. J. WEST

d-Glucuronic acid. FELIX EHRLICH AND KURT REHORST. *Ber.* **58B**, 1989-92 (1925); cf. *C. A.* **19**, 3169.—E. and R. have succeeded in obtaining the free *d*-glucuronic acid (I) in cryst. form by hydrolyzing the paired compd. (e. g. mentholglucuronic acid (II)) with dil. H_2SO_4 on the H_2O bath, removing the H_2SO_4 with excess of $\text{Ba}(\text{OH})_2$ or BaCO_3 , pptg. the Ba salt of I with alc., decompg. in moderately warm aq. soln. with H_2SO_4 , cautiously evapg., extg. the resulting sirup with alc. and concg. the ext. The I thus obtained in needles in 50-70% yield from II, m. 151° (decompn.), neutralizes the calcd amt of 0.1 *N* NaOH (phenolphthalein), $[\alpha]_D^{24}$ in H_2O (*c* 5.626) 11.73° (initial), 36.26° (final, after 1.5-2.0 hrs.) (the acid pptd. from alc. by Et_2O shows a const. $[\alpha]_D^{21}$ 36.30° immediately in H_2O); corresponding to its p_H value of 2.5-2.8, it is not sweet but has a pronounced acid taste comparable to that of AcOH ; it reduces Fehling soln. only on boiling, gives no ppt. with $\text{Pb}(\text{OAc})_2$, yields a basic Pb salt with basic Pb acetate and a basic Ba salt with excess of hot $\text{Ba}(\text{OH})_2$; cinchonine salt, m. $199\text{--}200^\circ$, $[\alpha]_D^{24}$ 135.0° (H_2O , *c* 1.23). Heated a long time in H_2O its rotation decreases and it yields a mixt. of varying amts of I and the anhydride. By means of the above method of prep. I its presence in beet saponins has been established.

C. A. R.

Coördinated compounds of the alkali metals. II. N. V. SIDGWICK AND F. M. BREWER. *J. Chem. Soc.* **127**, 2379-87 (1925).—The discovery of 4-covalent derivs. of ψ -indoxylspirocyclopentane (cf. *C. A.* **19**, 1140) led to further study to det. whether such derivs. are formed by simpler compds. which give chelate rings with multivalent metals, such as β -diketones, β -ketonic esters, *o*-hydroxyaromatic esters and aldehydes and *o*-nitrophenols, the alk. derivs. of which have hitherto been regarded as salts. Considerable exptl. evidence was obtained to show the existence of type I of the following types ($\text{X} = \text{C}$ or N) and numerous examples of II, III and IV were prepd. Examn. of

the alk. derivs. of the simple compds. mentioned showed them to belong to 1 of 3 classes: (1) salts; (2) non-polar chelate compds. which on sepn. change to a more stable ionized form; or (3) stable non-polar compds. The majority of compds. belong to class (1), including the Li derivs. of $\text{AcCH}_2\text{CO}_2\text{Et}$, CH_2Ac , BzCH_2Ac , $\text{NCCCH}_2\text{CO}_2\text{Et}$, Me salicylate, salicylaldehyde, *o*-nitrophenol, 3-nitro-*o*-cresol, quinizarin and the *K* analogs of the Na derivs. which belong to class (2). To class (2) belong the Na derivs. of alkyl- and phenylmalonic esters, 1-ketohydrindene-2-carboxylic esters and Et picrylmalonate and to

class (3) the Na derivs. of $\text{AcCH}_2\text{CO}_2\text{Et}$, $\text{AcCHEtCO}_2\text{Et}$, $[\text{CH}(\text{CO}_2\text{Et})_2]$, the K derivs. of $\text{AcCH}_2\text{CO}_2\text{Et}$, $\text{NCCH}_2\text{CO}_2\text{Et}$ and BzCH_2Ac . The replacement of H on the middle C atom of the 3 (as in esters of alkylmalonic acids) promotes stability of the nonpolar form. Many of these metal derivs. react with excess mother-substance to form unstable addn. compds., the identity of which could be established in no case, because of decompn. *Prepn. of compds.* Na deriv. of benzoylacetone, $\text{PhC}(\text{ONa})\text{:CHCOMe}$, no definite m. p., insol. in hydrocarbons, but on recrystn. from 96% EtOH it becomes sol. in PhMe, in consequence of formation of the hydrate $\text{C}_{10}\text{H}_8\text{O}_2\text{Na}\cdot 2\text{H}_2\text{O}$, m. 115° (loss of H_2O). A corresponding Li deriv., $\text{C}_{10}\text{H}_8\text{O}_2\text{Li}\cdot 2\text{H}_2\text{O}$, was prepd., though not free of anhyd. salt. The K compd. did not form a hydrate. Et sodioacetoacetate, m. 108° . Dihydrate, $\text{C}_8\text{H}_8\text{O}_3\text{Na}\cdot 2\text{H}_2\text{O}$ (cf. Eliot, *Rec. trav. chim.* 3, 240(1884)), m. 102° , decomps. on standing to a compd., m. 82° , which was also obtained by adding excess H_2O to Eliot's soln. of the Na deriv. and was probably the dihydrate of Na acetoacetate. This was confirmed by the fact that whereas an aq. soln. of the original dihydrate became turbid on acidification the decompn. product remained clear, but evolved CO_2 (cf. De Forcrand, *Ann. chim.* 5, 405(1895)). Na acetylacetone. Hydrate, $\text{C}_8\text{H}_7\text{O}_2\text{Na}\cdot 2\text{H}_2\text{O}$, very unstable, evolves H_2O on heating. K acetylacetone. Hydrate, very unstable, being hydrolyzed by its own H_2O . No Li deriv. could be prepd. Me lithiosalicylate. Hydrate, $\text{C}_8\text{H}_7\text{O}_3\text{Li}\cdot 2\text{H}_2\text{O}$, stable, loses H_2O gradually on heating, finally m. 278° . Li salicylaldehyde. Dihydrate, $\text{C}_7\text{H}_5\text{O}_2\text{Li}\cdot 2\text{H}_2\text{O}$, glistening yellow, gives colorless soln. in PhMe, evolves H_2O on heating, finally m. about 228° . Na salicylaldehyde, $\text{C}_7\text{H}_5\text{O}_2\text{Na}\cdot \text{C}_7\text{H}_5\text{O}_2$ (cf. Hantzsch, *Ber.* 39, 3089(1906)), yellow. Na o-nitrophenoxide, bright red, forms with salicylaldehyde an addn. compd., $\text{C}_6\text{H}_4\text{O}_2\text{NNa}\cdot \text{C}_7\text{H}_5\text{O}_2$, yellow, decomps. on heating. No similar compd. is formed from p- $\text{O}_2\text{NC}_6\text{H}_4\text{ONa}$, nor does Li form a corresponding deriv. K o-nitrophenoxide, red, absorbs H_2O to form a hydrate, $(\text{C}_6\text{H}_4\text{O}_2\text{NK})_2\cdot \text{H}_2\text{O}$ (cf. Fritzsche, *Ann.* 110, 153(1859); Frazer, *Am. Chem. J.* 30, 309(1903)), orange, forms with salicylaldehyde an addn. product difficult to purify, of the approx. compn. $\text{C}_6\text{H}_4\text{O}_2\text{NK}\cdot \text{C}_7\text{H}_5\text{O}_2$, when fresh, decomps. easily. Na deriv. of 3-nitro-o-cresol, red, gives with salicylaldehyde an addn. compd., $\text{C}_7\text{H}_5\text{O}_2\text{NNa}\cdot \text{C}_7\text{H}_5\text{O}_2$, yellow. K deriv., absorbs salicylaldehyde to form an unidentified addn. compd., Li deriv. Alk. salts of quinizarin: Na salt and K salt, deep blue-purple; Li salt, red-purple, all easily hydrolyze with sepn. of quinizarin. The Na salt gives with salicylaldehyde an addn. compd., $\text{C}_{14}\text{H}_8\text{O}_4\text{Na}_2\cdot 4\text{C}_7\text{H}_5\text{O}_2$, salmon-pink, decompd. by org. solvents, with sepn. of the original Na salt, but can be heated in H_2O without hydrolysis. The K salt also gave an addn. compd., $\text{C}_{14}\text{H}_8\text{O}_4\text{K}_2\cdot 4\text{C}_7\text{H}_5\text{O}_2$. These compds. are the first known 6-covalent compds. of the alk. metals. If their formulas are correct Li cannot form an analogous compd., for its covalency is limited to 4. The salt can, therefore, take up only 1 mol. of aldehyde for each Li atom. The Li salt, $\text{C}_{14}\text{H}_8\text{O}_4\text{Li}\cdot 2\text{C}_7\text{H}_5\text{O}_2$, has properties like those of the K and Na salts. C. C. DAVIS

Action of halogen on enolates of glutaconic dialdehyde and the synthesis of β -halopyridines. PAUL BAUMGARTEN. *Ber.* 58B, 2018-23(1925); cf. C. A. 19, 517.—The action of halogens on the simpler glutaconic aldehyde derivs., ROCH:CHCH:CHCHO (I, R = Na; II, R = Bz), results not in addn. at the double bond but in substitution, with formation of OCHCHXCH:CHCHO (III) and elimination of NaX or BzX . Whether the intermediate addn. products which are undoubtedly formed have the structure ROCHXCHXCH:CHCHO or ROCHXCH:CHCHXCHO cannot be detd., as both would at once change into the same III (or its tautomeric form). That the halogen in the III is on 1 of the α -C atoms is shown by the formation of β -halopyridines with NH_3 . The reaction of the halogens with the I was effected in H_2O or MeOH (in chlorination only MeOH can be used, as in H_2O the reaction follows a different course), with the II in CCl_4 or Et_2O . Thus, II in cold Et_2O with Cl gives $\text{BzOCH:CHClCH:CHCHO}$, m. 127° , identical with Dieckmann's product (*Ber.* 37, 4645(1904)), and giving with PhNH_2 $\text{PhNHCH:CClCH:CHCH:NHPhCl}$, bright red-violet, m. 119° (decompn.), which is also obtained in 1.2 g. yield from 1.5 g. I in cold MeOH treated with Cl and then with PhNH_2 in HCl and seps. from alc. with $2\text{H}_2\text{O}$, 1 of which is lost in vacuo over H_2SO_4 ; with hot alc. HCl this yields N-phenyl- β -chloropyridinium chloride; chloroplatinate, orange, m. 194° (decompn.). The free δ -hydroxy- γ -bromo- α , γ -butadiene- α -aldehyde could not be isolated from the reaction product of I and Br in either H_2O or MeOH but was identified as the benzoate, light yellow, m. 107.5° , or the dianilide HBr salt, blue-red microrodlets, m. $135-6^\circ$ (decompn.); its Na salt, distd. with steam after addn. of solid NH_4OAc , gives β - $\text{C}_6\text{H}_4\text{NBr}$, b₇₆₀ 169° ; chloroplatinate, m. 175° (decompn.). N-Phenyl- β -bromopyridinium iodide, from the dianilide HBr salt with hot alc. HBr and subsequent pptn. with KI, bright yellow, m. 247° (decompn.). α -Iodoglutaconic aldehyde (δ -hydroxy- γ -iodo- α , γ -butadiene- α -alde-

hyde), faintly brownish, m. about 90° (decompn.); benzoate, somewhat yellowish, m. 127°. α -Anilino- α,γ -butadiene- α -[aldehyde anil] *N,N'*-bis-di HI salt (3.4 g. from 1 g. I), violet-blue micronedles, m. 133-5° (decompn.), loses some HI on recrystn., decompd. by hot aq. alc. into *N*-phenyl- β -iodopyridinium iodide, yellow, m. 272° (decompn.). I (4 g.) treated in MeOH with I and then converted into the Na salt with NaOMe and refluxed with NH_4OAc gives 1.7 g. β -iodopyridine, m. 53.5°, very volatile even at room temp.; *HCl* salt, hygroscopic; chloroplatinate, yellow, m. 211° (decompn.). C. A. R.

Rupture of ring systems. RICHARD KUHN AND FRIEDRICH EBEL. *Ber.* 58B, 2088-94(1925).—Comments on the paper of Meisenheimer (*C. A.* 20, 190). C. A. R.

Oxidation of uric acid by iodine. WILHELMINE E. FÜRTH. *Biochem. Z.* 159, 130-40(1925).—One mol. of uric acid reacts with 3.5 atoms of I, giving urea, allantoin, NH_3 and CO_2 . Alloxan and oxalic acid are not formed directly, but the latter may be obtained by hydrolysis of one of the fractions with NaOH. W. D. L.

The constitution of lupeose. N. CASTORO. *Gazz. chim. ital.* 55, 463-7(1925)—C. reviews the earlier history of lupeose (I), the mol. wt. of which was unknown because of its amorphous state and the fact that it forms colloidal solns. C. (*C. A.* 5, 512) isolated I from *Cicer arietinum* and concluded that it was a tetrose consisting of 2 mols. of galactose and 1 mol. each of fructose and a *d*-rotatory monose. Later Schulze and Pfenniger (*C. A.* 5, 1272) concluded that the latter sugar is glucose and thus $\text{I} + 3\text{H}_2\text{O} \rightarrow 2$ mols. galactose + 1 mol. glucose + 1 mol. fructose. E. J. WITZEMANN

Behavior of glucose and certain other carbohydrates towards dyestuffs and towards potassium ferricyanide in an alkaline medium. EDMUND KNECHT AND EVA HIBBERT. *J. Chem. Soc.* 127, 2854-60(1925); cf. *C. A.* 19, 623, 1835.—In an alk. medium, glucose, levulose and certain other carbohydrates are oxidized to a definite degree by methylene blue and by K indigotintetrasulfonate (I). Glucose, glucosamine and galactose take up, under the conditions, exactly 3 and levulose 4, atomic proportions of O. $\text{K}_3\text{Fe}(\text{CN})_6$ can replace the dyestuffs in these estimations. When boiled for 2 min. with excess of NaOH in an atm. of N, both glucose and levulose neutralize an amt. of alkali corresponding exactly to the formation of 2 mols. of lactic acid. When glucose is boiled with excess of $\text{K}_3\text{Fe}(\text{CN})_6$ and KOH, the amt. of alkali neutralized (over and above that required to form $\text{K}_4\text{Fe}(\text{CN})_6$) represents exactly 3 equivs. of KOH. In the case of levulose, this is approx. 4 equivs. Glucuronic acid can be estd. quant. by titration with I. The volumetric osazone titration method may also be employed for the purpose. In the presence of alkali glucose is also oxidized quant. by kitone blue and by rosinduline. In the former case, 2 and in the latter, 1 atomic proportion of O is supplied by these dyestuffs. Neither lactic, saccharic, mucic nor gluconic acid reduces methylene blue when boiled with this dyestuff in the presence of KOH. C. J. WEBER

Transformations of the sugar nitrates. J. W. H. OLDHAM. *J. Chem. Soc.* 127, 2840-5(1925).—Trimethylglucosan in a mixt. of fuming HNO_3 and CHCl_3 contg. a little P_2O_5 gives after 19 hrs. at room temp. 2,3,5-trimethylglucose 1,6-dinitrate, m. 86°. $[\alpha]_D$ 149.3° (CHCl_3 , *c* 2.3193), 151.7° (Me_2CO , *c* 1.463), 144.8° (MeOH , *c* 1.508) and 147.2° (60% fuming HNO_3 + 40% CHCl_3 by vol., *c* 2.915). Boiled in 5% soln. in MeOH for 0.5 hr. with BaCO_3 , there results 90% of trimethylmethylglucoside 6-nitrate, m. 53-4°, n_D 1.4565 (superfused), $[\alpha]_D$ -5.2° (CHCl_3 , *c* 2.0653), -4.4° (Me_2CO , *c* 3.5845), -1.3° (MeOH , *c* 3.3413). Hydrolysis with Fe dust in glacial AcOH in not more than 5% concn. gave a good yield of trimethylmethylglucoside; NaI gives a good yield of the iodohydrin. Triacetylglucosan (5 g.) in a mixt. of 30% CHCl_3 and 70% redistd. HNO_3 by vol., to which is added 10 g. solid N_2O_5 and the whole made up to 100 cc. with CHCl_3 , on standing 110 hrs. at room temp., gives about 30% of triacetylglucose 1,6-dinitrate(?) (I), m. 132-3°, $[\alpha]_D$ 144.2° (HNO_3 + CHCl_3 , *c* 5.0). Boiled with AcOH, Ac_2O and AcONa for 1-1.5 hrs., there results tetraacetylglucose 6-nitrate, m. 142-3°, $[\alpha]_D$ 23.2° (AcOH , *c* 2.494), 27.2° (CHCl_3 , *c* 2.038), reduces Fehling soln. strongly on boiling. Further hydrolysis with Fe in AcOH gives tetraacetylglucose, m. 126.5-7.5°, $[\alpha]_D$ 9.8° (CHCl_3 , *c* 0.816). I reacts with difficulty with $\text{MeOH}\cdot\text{BaCO}_3$, even when $\text{C}_2\text{H}_5\text{N}$ is added, giving 50-60% of triacetyl-methylglucoside 6-nitrate (II), m. 133.5-4.5°, $[\alpha]_D$ -14.3° (CHCl_3 , *c* 5.964), -14.1° (Me_2CO , *c* 2.6913). Hydrolysis with Fe and AcOH gives triacetyl-methylglucoside, m. 134-4.5°, $[\alpha]_D$ -19.1° (CHCl_3 , *c* 1.514). II, treated with 5% $\text{MeOH}\cdot\text{Me}_2\text{NH}$, gave *Me* glucoside 6-nitrate, which did not cryst., but was identified by methylating to trimethylmethylglucoside 6-nitrate. Triacetyl-methylglucoside 6-iodohydrin, m. 111-2.5°, $[\alpha]_D$ 0.9° (CHCl_3 , *c* 3.027); Me_2NH gives a poor yield of *Me* glucoside 6-iodohydrin, m. 157-8°, $[\alpha]_D$ -18.1° (CHCl_3 , *c* 1.677). The mother liquors from the crystals of I gave an acetoniropentose (triacetyl-pentose ni-

trate), $m.$ 168–9°, $[\alpha]_D$ 92.0° (CHCl_3 , c 1.214). This indicates that during the nitration degradation to the pentose series had taken place to a limited extent. C. J. WEST

Partial hydrolysis of sucrose-phosphoric acid to *d*-fructose and *d*-glucose-phosphoric acid. J. HATANO. *Biochem. Z.* 159, 175–8 (1925).—Sucrose-monophosphoric acid is gently hydrolyzed in dil. acid and glucose-phosphoric acid pptd. as the Ca or Ba salt by the addn. of EtOH. From the alc. residue *d*-fructose is obtained. W. D. L.

Polymerization of β -glucosan. The constitution of synthetic dextrans. J. C. IRVINE AND J. W. H. OLDHAM. *J. Chem. Soc.* 127, 2903–22 (1925).—Polymerization of β -glucosan by heating 7 g. with 0.1 g. Zn dust at 250° *in vacuo* for 60–75 min. occurs without loss in wt. Fractional pptn. from H_2O by EtOH gives 3 dextrans: Dextrin I, *heptagluconan*, the less sol. of the 3, slightly hygroscopic, gives a pale yellow soln. in H_2O which is non-reducing and has $[\alpha]_D$ 83.9° for c 2.08; *triacetate*, $m.$ 142°, $[\alpha]_D$ 85.1° (50% EtOH, c 2.2315); heating I 2 hrs. with MeOH nearly satd. with HCl gives Me glucoside. Dextrin II, *tetragluconan*, intermediate in soly., also is hygroscopic, $[\alpha]_D$ 60.7° (H_2O) and yields the same triacetate as I; it is readily converted into Me glucoside. Dextrin III, *trigluconan*, $[\alpha]_D$ 29.9°, also yields the same triacetate as I and is converted into Me glucoside in the usual way. Methylation of I with Ag_2O and MeI causes the introduction of 2 Me groups, giving an easily powdered glass with $[\alpha]_D$ 76.0° (CHCl_3 , c 0.6035); Me_2SO_4 gives a product approx. the tri-Me stage, with $[\alpha]_D$ 89.4° (CHCl_3 , c 2.745); mol. wt. in freezing C_6H_6 1446 (calcd., $\text{C}_{63}\text{H}_{112}\text{O}_{36}$, 1428). Heating with MeOH, nearly satd. with HCl for 15 hrs. at 70° gives a colorless sirup, hydrolyzed by 3% aq. HCl to a soln. of methylated glucoses with $[\alpha]_D$ 68.4°; from this cryst. tetramethylglucose was obtained, the remaining being a mixt. of di- and trimethylglucoses in unknown proportions. II gives with Me_2SO_4 a *tri-Me deriv.*, glass with $[\alpha]_D$ 68.7° (MeOH, c 1.3625), 70.5° (Me_2CO , c 1.958), 61.2° (CHCl_3 , c 2.900); mol. wt. in freezing C_6H_6 , 873 (calcd. for $\text{C}_{36}\text{H}_{64}\text{O}_{20}$, 816); hydrolysis as above gave a mixt. of di-, tri- and tetramethylglucoses. III gave a *tri-Me deriv.*, glass with $[\alpha]_D$ 53.5° (CHCl_3 , c 2.1035), 56.4° (Me_2CO , c 2.048), 52.8° (MeOH, c 1.753); mol. wt. in freezing C_6H_6 , 595 (calcd. for $\text{C}_{27}\text{H}_{48}\text{O}_{15}$, 612). Heated *in vacuo*, approx. 0.5 of the material distd. at 180–200° and 0.5 mm., but this is evidently due to polymerization, since the product is a mobile sirup with n_D 1.4770 and $[\alpha]_D$ 23.9° (CHCl_3). The end products of the acid hydrolysis are the same as for the II and I. In place of sepg. the polyglucosans by pptn. and then methylating, it is more effective and economical to alkylate the total polymerized product and sep. the resulting methylated compds.; thus, from 60 g. glucosan there was obtained 55 g. methylated product, which gave: 17% trimethylglucosan, 23.6% di-[trimethylglucosan] (IV) and 57.8% poly[trimethylglucosan] (V). IV, pale yellow sirup, $b_{0.2}$ 205–10°, n_D 1.4720, $[\alpha]_D^{20}$ 46.5° (CHCl_3 , c 1.9515), 48.3° (MeOH, c 1.8790), 51.8° (MeCO, c 2.0040). With MeOH and HCl there result 46.6% dimethylmethylglucoside and 53.4% of the tetra-Me deriv., which are very nearly the proportions required for equal mols. (47.1 and 52.9). V showed $[\alpha]_D$ 63.3° (CHCl_3 , c 1.850), 66.6° (Me_2CO , c 2.266), 64.4° (MeOH, c 1.755). Conversion into glucosides gave: 35.5% 2,3,5-trimethylmethylglucoside, 33.5% 2,3,5-tri-Me deriv., 26% di-Me and 5% Me derivs., the last probably being due to incomplete methylation; here again the % are almost identical with those required for equal mols. Attempts to establish the constitution of the dimethylglucose failed; the Me glucoside $b_{0.4}$ 190°, n_D 1.4743. The mechanism of the polymerization is discussed, also the applicability of the methylation process to the structural problems of carbohydrates.

C. J. WEST

Methylation experiments with polysaccharides. L. SCHMID. *Ber.* 58B, 1963–5 (1925).—Seeking as mild as possible a method of methylating carbohydrates, S. tried the action of CH_2N_2 on cellulose (I), lichenin (II), inulin (III) and sol. starch (IV). I does not react at all with CH_2N_2 . When the other hydrocarbons, dried *in vacuo*, are treated with CH_2N_2 in abs. Et₂O, protected from atm. moisture by a Hg seal, there is an evolution of gas which begins soon with III and IV but is hardly noticeable with II; moreover, it soon ceases. On adding small amts. of H_2O , N is again evolved and within a few hrs. the yellow CH_2N_2 solns. are decolorized. Addn. of fresh CH_2N_2 is repeated until N is no longer evolved (7 times). The product so obtained from IV can be sepd. into an alc.-sol. and an alc.-insol. fraction, contg. 22.24 and 21.51% MeO, resp., which correspond to more than the mono-ether (17.60%); neither fraction reduces Fehling soln. and with I they give a dark-red color; the alc.-sol. fraction is easily sol. in H_2O , the other less so. The product from II likewise yields an alc.-insol. and an alc.-sol. fraction, with 17.37 and 21.62% MeO (calcd. for the mono-ether, 17.37%), which do not reduce Fehling soln. The product from III is very easily sol. in alc. and H_2O ; the MeO content (25.24%) corresponds to 3 MeO groups for 2 $\text{C}_6\text{H}_{10}\text{O}_5$ complexes; it does not reduce Fehling soln. and is less sol. in hot than in cold H_2O . C. A. R.

Alkali compounds of carbohydrates. L. SCHMID AND B. BECKER. *Ber.* **58B**, 1966-8(1925).—Thinking that the impossibility of completely methylating carbohydrates with CH_2N_2 (cf. preceding abstr.) might be due to the fact that the reaction system is heterogeneous, S. and B. attempted to effect the methylation in a homogeneous system by converting the carbohydrates in liquid NH_3 soln. by means of alkali metals into the alcoholates which then, by double decompn., should give the desired ethers. In all cases, addn. of 1 atom alkali metal to 1 mol. of the carbohydrate or alc. gives products whose compn. agrees well with that calcd. for the expected monoalcoholate, but with more than 1 atom alkali metal, the reaction proceeds in an entirely different way; with 1 atom, the reaction is complete within a few min., as shown by the decolorization of the deep blue soln., while with more than 1 atom it requires several hrs. Moreover, the sensitiveness of the product to air increases parallel with the increase in the amt. of metal; the product from 1 mol. inulin with 3 atoms K becomes brown in the air, evolves heat and emits vapors of empyreumatic odor. The metal content of these products does not correspond to a di- or trialcoholate; those obtained with 3 atoms Na or K contain 1-5% N. Ca does not react. The carbohydrates studied were inulin, lichenin, sol. starch, mannitol, and α -Me glucoside. A sketch of the app. used is given. C. A. R.

Chemical nature of the hop resin acids. II. HEINRICH WIELAND (WITH ERWIN MARTZ AND HEINZ HOEK). *Ber.* **58B**, 2012-7(1925); cf. C. A. **19**, 1428; Wollmer, C. A. **19**, 2042.—Isolumulinic acid, which in the 1st paper was assumed to be a 1,2,4-triketocyclopentane, RCH CO CHR' CO CO (I), gives with KOH at 180° 75-

80% $(\text{CO}_2\text{H})_2$, 52% of $\text{MeCOCH}_2\text{CHMe}_2 + \text{MeCO}(\text{CH}_2)_3\text{CHMe}_2$ and 76% $\text{Me}_2\text{CHCH}_2\text{CO}_2\text{H} + \text{MeCH}(\text{CH}_2)_3\text{CO}_2\text{H}$, whence R must be $\text{Me}_2\text{CHCH}_2\text{CH}_2$ and R' $\text{Me}_2\text{CHCH}_2\text{CO}$, and humulone, the original hop resin, must have the structure

$$\text{Me}_2\text{CHCH}:\text{CHCH} \overset{6}{\text{C}}(\text{O}) \overset{1}{\text{C}}(\text{COCH}_2\text{CHMe}_2) \overset{2}{\text{C}}(\text{OH}) \overset{3}{\text{C}}(\text{OH})(\text{CH}:\text{CHCHMe}_2) \overset{4}{\text{C}}(\text{O}) \overset{5}{\text{C}}(\text{O}) \text{ (II)},$$

only the position of the 2nd double bond in the side chains (that in the chain on C atom 4 is established) being still uncertain. This double bond is still present in humulinic acid and in the hydrocarbon $\text{C}_{15}\text{H}_{28}$ obtained by reduction of III by the Clemmensen method. Similarly, lupulone, the 2nd cryst. hop resin acid, must have the structure II with a 2nd C_6H_5 residue instead of HO on C atom 4. C. A. R.

Cyclohexyl ether. V. N. IPATIEV AND I. ORLOV. *Compt. rend.* **181**, 793-5(1925).—In hydrogenating phenol under pressure over NiO I. obtained (C. A. **3**, 1014) a fraction, b. $272-5^\circ$ (I), thought to be cyclohexyl ether. I. and O. treated I for 36 hrs at 290° under pressure with Al_2O_3 , CuO and H_2 and obtained cyclohexylcyclohexene (II) and dicyclohexyl (III), $b_{37} 237-8.5^\circ$, $d_4^{20} 0.8835$. The formation of II and III favors the view that I is cyclohexylhexanol. Reducing diphenylene oxide with H_2 at 140 atm at 290° for 36-40 hrs gave III, b. $236-7.5^\circ$, $d_4^{20} 0.8919$. A small amt. of cyclohexylcyclohexene and cyclohexylhexanol also was formed, indicating a splitting of the O-C bond. The difference between III as obtained by the two methods may be due to stereoisomerism. D. H. POWERS

Monochloro-*o*-methylcyclohexanone. M. GODCHOT AND P. BEDOS. *Compt. rend.* **181**, 919-21(1925); cf. C. A. **19**, 2644.—Chlorination of *m*- and *p*-methylcyclohexanone has already been discussed (C. A. **18**, 1990). *o*-Methylcyclohexanone (I) chlorinated gives only a single mono-Cl deriv., $b_{14} 78-9^\circ$, $d_{16} 1.099$, $n_D 1.4696$, believed to be 2-chloro-2-methylcyclohexanone (II). II distilled with quinoline gives 60% of 1-methyl- Δ^4 -cyclohexen-2-one (III), b. $170-1^\circ$, $d_{17} 0.956$, $n_D^{17} 1.4646$, M. R. 31.78, (calcd. 32.01). Oxime of III, m. $142-3^\circ$. III and MeMgI give 1,2-dimethyl- Δ^6 -cyclohexen-2-ol, $b_{23} 71-3^\circ$, $d_{16} 0.9313$, $n_D^{15} 1.4647$, M. R. 37.39, (calcd. 37.95). The phenylurethan of III was prepd. II with MeMgI gives 1,1,2-trimethyl- Δ^2 -cyclohexene, b. $144-6^\circ$, $d_{14} 0.862$, $n_D^{14} 1.4590$. D. H. POWERS

The mechanism of reduction. IV. H. J. PRINS. *Rec. trav. chim.* **44**, 876-88 (1925). (In English).—In a previous paper (C. A. **18**, 1604) the action of PhNO_2 in AcOH on Zn was studied. In this paper the action of these compds. on Pb was studied. The expts. were carried out like those with Zn. A rectangular piece of sheet Pb with a hole near one edge was suspended from a glass hook in the soln. which was kept at const. temp. After each treatment the piece was dipped in a rapid current of H_2O for 20 secs. and then washed in pure Me_2CO and dried at 80° for 20 secs. Washing with Me_2CO proved to be the best way to avoid a change in velocity of soln. through impurities from the liquid used for washing. In general the action of PhNO_2 in AcOH

on Pb is the same as on Zn; the Pb is rapidly dissolved at room temp. and the velocity of soln. can be calcd. with the aid of the same formula as was used for Zn. In both cases up to a critical concn. of PhNO_2 the velocity of soln. is directly proportional to the concn. of the PhNO_2 . Expressed in mols. per unit of surface the velocity of soln. is the same for Zn as for Pb. This is valid from zero to the critical concn. of the PhNO_2 . This and the low temp. coeff. proves the velocity to be a velocity of diffusion. Above the critical concn. the velocity depends on the condition of the surface of the metal, which in its turn depends upon the velocity of diffusion of the acetate from the metallic surface. The type of curve for concns. above the critical one is detd. by the ratio between K_2 and K_1c_K . For Zn $K_2 < K_1c_K$ while for Pb $K_2 > K_1c_K$. The influence of the condition of the surface is also apparent from the expts. with AcOH, which confirms P.'s opinion that the reaction takes place between PhNO_2 and a mol. of AcOH adsorbed on the surface of the metal and, therefore, in an activated condition. On the other hand the reaction can also take place probably between adsorbed H^+ ions and PhNO_2 as is indicated by the increase in velocity upon adequate diln. of the AcOH with H_2O . The condition of the surface not only det. the velocity of the reduction but may also change its course. If, e. g., the active surface of the metal is small compared with its total surface the chance that 2 or more elemental spaces are close together will be much less than in the reverse case. Many compds. can react with one another when taking up H_2 , e. g., aldehydes, ketones (especially unsatd ketones). This condensation reaction will be promoted if the mols. are close together while taking up H_2 , whereas it can be prevented if the active spaces on the metal are small and widely scattered. The expts. here described give a method of realizing this condition e. g. by keeping the metal surface covered by the salt. This can be done by choosing an appropriate concn. of the reducible compd. or by diminishing the velocity with which the metal salt diffuses from the metal either by lowering the temp., by choosing an appropriate metal or by changing the medium. The latter may be done by satg. the medium with the salt of the metal or by choosing a medium in which the salt is only sparingly sol. There are, of course, other factors that influence the course of the reaction, e. g., the magnitude of the activation of the acid, the magnitude of activation of the reducible compd. and the individual velocity with which each mol. takes up H_2 . I. J. WITZEMANN

Isomeric changes in aromatic compounds. I. Conversion of diacylanilides into acylaminoketones. A. W. CHAPMAN. *J. Chem. Soc.* 127, 2818–20 (1925).—Passing a current of dry HCl through a fused PhNAC_2 gives the acid chloride and an acylaminoketone. PhNAC_2 (20 g.) gives 6.7 g. AcCl and 11.5 g. PhNHAc ; PhNBz_2 (10 g.) gives 2.1 g. BzCl and 4.8 g. PhNHBz . PhNAC_2 (20 g.) and ZnCl_2 , heated at $140\text{--}60^\circ$ while HCl was passed through for 4.5 hrs., gave $p\text{-AcNHC}_6\text{H}_4\text{Ac}$, isolated as $\text{H}_2\text{NC}_6\text{H}_4\text{Ac}$ (2 g.). This product was not formed when the HCl was omitted from the reaction. When $p\text{-H}_2\text{NC}_6\text{H}_4\text{Ac}$ was heated alone no PhNAC_2 was formed. C. J. WEST

***o*-Aminophenylhydrazine and some interesting heterocyclic compounds derived from it.** PRAPHULLA CHANDRA GUHA AND SUDHANYA KUMAR RAY. *Quart. J. Indian Chem. Soc.* 2, 83–94 (1925); cf. *Ber.* 22, 240, 2810, 3221.—10 g. $o\text{-O}_2\text{NC}_6\text{H}_4\text{NHNH}_2\cdot\text{HCl}$ was reduced with SnCl_2 and HCl; the soln. was concd. *in vacuo* and the *o*-aminophenylhydrazine-HCl (I) purified by pptn. with Et_2O from alc. Yield, 3–4 g., m. $263\text{--}5^\circ$ (decompn.). *Dibenzylidene deriv.*, m. $206\text{--}7^\circ$. *Free base*, from I and NH_4OH or NaOAc (crystd. from dil. alc. in absence of air), m. $295\text{--}302^\circ$ (decompn.). **4-Phenyl-1-*o*-phenylthiocarbamidophenylthiosemicarbazide**, $\text{C}_{18}\text{H}_{14}(\text{NHCNHPH})\text{NHNHCNHPH}$, from I and PhNCS , m. 80° . **4-Tolylthiocarbamidophenylthiosemicarbazide**, from I and $p\text{-MeC}_6\text{H}_4\text{NCS}$, m. 282° . **2-Thio-1,2,3,4-tetrahydro-5,6-benzo-1,3,4-triazine**, from I, alc. KOH, and CS_2 , m. $298\text{--}300^\circ$; *Bz deriv.*, m. 174° ; *disulfide*, m. $208\text{--}10^\circ$. **Benzo-ketotetrahydrotriazine**, from I and urea, m. $310\text{--}2^\circ$. **Benzoheptatriazine**, from I and glycol, m. $212\text{--}4^\circ$ (decompn.). On reduction, $o\text{-O}_2\text{NC}_6\text{H}_4\text{NHNHCNHPH}$ (from $o\text{-O}_2\text{NC}_6\text{H}_4\text{NHNH}_2$ (II) and $\text{H}_2\text{NCSNHPH}$) gave **1-*o*-aminophenyl-4-phenylthiosemicarbazide-HCl** (III), m. $253\text{--}5^\circ$ (decompn.), gave a red dye on diazotization and coupling with β -naphthol, and **2-phenylimino-1,2,3,4-tetrahydro-5,6-benzo-1,3,4-triazine**, m. $150\text{--}1^\circ$. III and Ac_2O gave a compd., m. 152° . II and $\text{C}_6\text{H}_5\text{NCS}$ gave **1-*o*-nitrophenyl-4-allylthiosemicarbazide**, m. $164\text{--}5^\circ$. On reduction, the benzal deriv. of II gave **μ -phenylbenzimidazole-HCl**, m. above 306° ; *free base* m. $288\text{--}9^\circ$. II and $o\text{-HOC}_6\text{H}_4\text{CHO}$ gave a deriv. (IV), m. 190° , which dyed wool orange-red from an acid bath. *Bz deriv.* of IV, m. 180° . D. W. MACARDLE

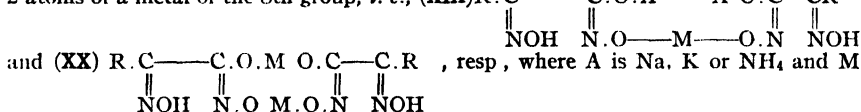

Preparation of *p*-bromophenylhydroxylamine by the emulsification process. A modification. R. D. HAWORTH AND ARTHUR LAPWORTH. *J. Chem. Soc.* 127, 2970 (1925); cf. C. A. 15, 2838.—Reduction of $p\text{-BrC}_6\text{H}_4\text{NO}_2$ by the method previously described is often unsuccessful. The emulsification of 5 g. $p\text{-BrC}_6\text{H}_4\text{NO}_2$, 40 cc. C_6H_6 ,

120 g. of reducing soln. and 5 g. CaCl_2 and after 0.5 hr. adding 5 g. solid NH_4Cl gives 2.7-3.4 g. $p\text{-BrC}_6\text{H}_4\text{NHOH}$. C. J. WEST

The dioximes. XXIV. G. PONZIO. *Gazz. chim. ital.* 55, 311-23 (1925).—The compd. $\text{Ph}(\text{C}_2\text{N}_2\text{O}_2)\text{H}$ which Scholl (*Ber.* 23, 3503 (1890)) considered to be the phenylglyoxime peroxide is, according to P. (*C. A.* 17, 3875, 3876; Avogadro, *C. A.* 18, 1491) the oxide of benzoyl cyanide oxime (I) $\text{PhC}(\text{:NOH})\text{C}\equiv\text{N}=\text{O}$ or $\text{PhC}(\text{:NOH})\text{C}=\text{N}-\text{O}$, and adds NH_3 and PhNH_2 , giving phenyl aminoglyoxime and phenylamino-

phenylglyoxime (III) (Wieland, *Semper*, *C. A.* 2, 1012; P., *C. A.* 17, 2267, 3874). II and III were the α -forms and P. expected I to add H_2O giving phenylhydroxyglyoxime but it is stable toward H_2O as well as toward PhNHNH_2 . P. and Ruggeri (*C. A.* 18, 661) tried to replace Cl in $\text{PhC}(\text{:NOH})\text{C}(\text{:NOH})\text{Cl}$ in aq. Na_2CO_3 and obtained the dioxime of dibenzoylglyoxime peroxide (IV). With $\text{Ac}_2\text{O} + \text{NaOAc}$ IV gave the *di-Ac deriv.* (V) $\text{PhC}(\text{:NOAc})(\text{C}_2\text{N}_2\text{O}_2)\text{C}(\text{:NOAc})\text{Ph}$, m. 128°. $\text{PhC}(\text{:NOAc})\text{C}(\text{:NOAc})\text{Cl}$ in Et_2O with 5% Na_2CO_3 or heated in C_6H_6 , with AgOBz also gave V, confirming its constitution and that of IV. Werner and Buss (*Ber.* 27, 2197 (1894)) state that $\text{Ph}(\text{:NOH})\text{Cl}$ (VI) is converted by Na_2CO_3 into diphenylglyoxime peroxide but P. found that benzohydroxamic acid, $\text{PhC}(\text{:NOH})\text{OH}$, is formed if 5 g. VI is treated with 20 g. NaOAc in 50 cc. of 50% AcOH . After some time the soln. is neutralized with NaOH , filtered, treated with a little NH_4OH and then BaCl_2 to ppt. the Ba salt, $(\text{C}_7\text{H}_5\text{O}_2\text{N})_2\text{Ba}$. This with dil. H_2SO_4 gives the free acid. 5 g. $\text{PhC}(\text{:NOH})\text{C}(\text{:NOH})\text{Cl}$ with 20 g. NaOAc in 50 cc. of 50% $\text{AcOH} + 25$ cc. EtOH were kept at 40-50° until limpid. The mixt. was dild. with H_2O , neutralized with NaOH and treated with 20% $\text{Ni}(\text{OAc})_2$. A red ppt. of the Ni-Na complex of phenylhydroxyglyoxime (VII) was obtained, which when decompd. with dil. H_2SO_4 gave the free compd. m. 191° (decompn.). VII was also obtained by the action of NH_4OH on $\text{BzC}(\text{:NOH})\text{OH}$ and on *Et* α -oximinophenylacetate (cf. a later paper for prepn.). The last method is the most convenient way of prepg. VII. With FeCl_3 solns. of VII give a red color and at 100° they attack Ni with the evolution of H_2 and the formation of the Ni salt. VII in EtOH with 0.5 mol. NaOH ppts. the Na salt, $\text{C}_7\text{H}_5\text{O}_2\text{N}_2\text{Na} \cdot \text{C}_5\text{H}_5\text{O}_2\text{N}_2 \cdot 2\text{H}_2\text{O}$; the corresponding K and NH_4 salts (without H_2O of crystn.) were obtained similarly. A soln. of the Na salt added to AgNO_3 ppts. the Ag salt, $\text{C}_7\text{H}_5\text{O}_2\text{N}_2\text{Ag} \cdot \text{C}_5\text{H}_5\text{O}_2\text{N}_2\text{Ag}$. *p-Tolylhydroxyglyoxime* (VIII), m. 186° (decompn.), was prepd. like VII from *p*-tolylchloroglyoxime, $\text{MeC}_6\text{H}_4\text{C}(\text{:NOH})\text{C}(\text{:NOH})\text{Cl}$ (prepn. to be described in paper XXVII). VIII with FeCl_3 gives a wine-red color; with $\text{Cu}(\text{OAc})_2$ a green ppt. insol. in dil. AcOH ; with $\text{Ni}(\text{OAc})_2$ a yellow ppt. sol. in dil. AcOH , slowly in excess of $\text{Ni}(\text{OAc})_2$ soln. and easily in NH_4OH with red color. VIII is identical in all its properties with *p*-methylbenzoylformohydroxamic acid (IX) obtained by the action of NH_2OH on $\text{MeC}_6\text{H}_4\text{COC}(\text{:NOH})\text{OH}$ by Gastaldi (*C. A.* 19, 285). P. believes that the supposed α - and β -forms of IX are both one substance for reasons given. Some comments on results in earlier papers are not abstracted. XXV. L. AVOGADRO AND G. TAVOLA. *Ibid.* 323-30.—Meyer and Auwers (*Ber.* 21, 3510 (1888)) and Dittrich (*Ber.* 23, 3589 (1890)) did the only existing work on di-Me ethers of the glyoximes $\text{RC}(\text{:NOH})\text{C}(\text{:NOH})\text{R}$, but encountered insuperable difficulties. In attacking this subject, A. and T. went back to the α - and β -phenylglyoxime (cf. P. and A., *C. A.* 17, 2268, 3874; P. and Bernardi, *C. A.* 18, 1490) and in this paper studied the ethers of methylglyoxime (X). X in 20% NaOH was treated gradually with a little more than the calcd. amt. of Me_2SO_4 with cooling and sepd. the *di-Me ether* of X, $\text{MeC}(\text{:NOMe})\text{C}(\text{:NOMe})\text{H}$, as a liquid, b. 145.5-6.5°; it is unchanged when treated with Cl in CHCl_3 ; in H_2O - EtOH with NaOH , NH_3 is slowly evolved and NaOAc is formed. X was treated with 1 mol. Me_2SO_4 as above and the di-Me ether sepd. with Et_2O ; the alk. liquid was acidified with dil. H_2SO_4 with ice-cooling and the *mono-Me ether* (XI), $\text{MeC}(\text{:NOMe})\text{C}(\text{:NOH})\text{H}$, m. 98-9°, was pptd. as a solid. In NaOH , XI is sol. and with excess Me_2SO_4 is converted into the di-Me ether. XI heated with $\text{PhNHNH}_2 + \text{AcOH}$ gives methylglyoxal osazone, m. 146°. XI with $\text{Ac}_2\text{O} + \text{NaOAc}$ gave the *Ac deriv.*, $\text{MeC}(\text{:NOMe})\text{C}(\text{:NOAc})\text{H}$, m. 43°. XI in CHCl_3 with Cl_2 gave methylchloroglyoxime mono-Me ether (XII), $\text{MeC}(\text{:NOMe})\text{C}(\text{:NOH})\text{Cl}$, m. 49°. XII in abs. EtOH with gaseous NH_3 gave methylaminoglyoxime mono-Me ether (XIII), m. 99°. With $\text{BzCl} + 15\%$ NaOH XI gave the *Bz deriv.*, $\text{MeC}(\text{:NOMe})\text{C}(\text{:NOBz})\text{NH}_2$, m. 134-5°. XIII or methylamino glyoxime with a small excess of Me_2SO_4 in 20% NaOH gave the *di-Me ether* of XIII as a colorless liquid, b. 192°. XI in 10% NaOH with the calcd. amt. of PhN_2Cl was allowed to react 24 hrs., filtered and acidified with AcOH to ppt. *β -methylphenylglyoxime mono-Me ether* (XIV), $\text{MeC}(\text{:NOMe})\text{C}(\text{:NOH})\text{Ph}$, m. 99°. XIV with $\text{Me}_2\text{SO}_4 + 20\%$ NaOH gave the corresponding di-Me ether, m. 84°, identical with that previously obtained

(C. A. 19, 262). The *Ac deriv.*, m. 63°, and the *Bz deriv.*, m. 113–4°, of **XIV** are obtained by the usual methods. Dimethylglyoxime treated with $\text{Me}_2\text{SO}_4 + 20\%$ NaOH sepd. the *di-Me ether*, $\text{MeC}(:\text{NOMe})\text{C}(:\text{NOMe})\text{Me}$, m. 44°; heated with PhNHNH_2 in EtOH, it gives the osazone of Ac_2 , m. 242°. Diaminoglyoxime treated similarly gave the *di-Me ether*, $\text{H}_2\text{NC}(:\text{NOMe})\text{C}(:\text{NOMe})\text{NH}_2$, m. 144°, which heated with $\text{Ac}_2\text{O} + \text{NaOAc}$ gives $\text{Ac}_2\text{NC}(:\text{NOMe})\text{C}(:\text{NOMe})\text{NAC}_2$, m. 205°. **XXVI**. G. PONZIO AND G. RUGGERI. *Ibid* 453–62 (1925).—Nothing is known about the complex internal salts of hydroxyglyoximes (**XV**), $\text{RC}(:\text{NOH})\text{C}(:\text{NOH})\text{OH}$. P. and R. intend to study the properties of the **XV** from the viewpoint of the Werner theory but before doing so wished to obtain a more general method of prepn. than the $\text{NaOAc} + \text{HOAc}$ method described above (paper **XXIV**). This was attained by an extension of Lossen's method of prepg. hydroxamic acids (**XVI**) from RCO_2Et . By considering **XVI** as hydroxyoximes it was possible that **XV** would be formed similarly from α -oximino-acid esters, $\text{RC}(:\text{NOH})\text{CO}_2\text{Et}$, by the action of NH_2OH . In this way nearly calcd. yields of mono-hydroxyglyoxime, $\text{HC}(:\text{NOH})\text{C}(:\text{NOH})\text{OH}$ (of interest because of its relation with hydroxyfurazan and fulminic acid) and of methyl-, ethyl-, phenylhydroxyglyoxime, etc., were obtained. A concd. aq. soln. of MeCOCO_2Et treated with an equimol. amt. of $\text{NH}_2\text{OH} \cdot \text{HCl}$, pptd. $\text{MeC}(:\text{NOH})\text{CO}_2\text{Et}$ (**XVII**), m. 100°. **XVII** in EtOH was treated with 1 mol. NH_2OH and after 6–8 hrs., 1 mol. EtOK and gave the K salt $\text{C}_3\text{H}_5\text{O}_3\text{N}_2 \cdot \text{C}_2\text{H}_5\text{O}_3\text{N}_2\text{K}$ in 90% yield. If Na is used the Na salt $\text{C}_3\text{H}_5\text{O}_3\text{N}_2 \cdot \text{C}_2\text{H}_5\text{O}_3\text{N}_2\text{Na} \cdot \text{H}_2\text{O}$ is obtained in smaller yield. Either salt in H_2O with dil. H_2SO_4 gives methylhydroxyglyoxime (**XVIII**), decomps. 150–60°. The K salt explodes with great violence at 115°. The hydroxyglyoximes form 2 series of internal complex salts: (1) salts that contain an atom of a metal of the 8th group and an atom of an alk. metal: (2) salts that contain 2 atoms of a metal of the 8th group, *i. e.*, (**XIX**) $\text{R} \cdot \text{C} \begin{array}{c} \parallel \\ \text{NOH} \end{array} \text{C} \begin{array}{c} \parallel \\ \text{N.O} \end{array} \text{M} \begin{array}{c} \parallel \\ \text{O.C} \end{array} \text{C} \begin{array}{c} \parallel \\ \text{O.N} \end{array} \text{R}$, resp. where A is Na, K or NH_4 and M

is Ni, Cu or Co. The compds. of the 1st series are undoubtedly derived from 2 mols. of hydroxyglyoxime, are well crystd., have an abnormal color, are sol. in H_2O and behave crytometrically like electrolytes, contain the 8th group element as a complex stable anion and are pptd. by electrolytes having an ion in common as well as by other strong electrolytes. The compds. of the 2nd series are colloidal. **XVIII** in H_2O heated on the H_2O -bath with the calcd. amt. of aq. $\text{Ni}(\text{OAc})_2 + \text{a little AcOH}$ seps. *Ni* [dimethylhydroxyglyoxime] nickelate, (**XXI**) XX , $\text{M} = \text{Ni}$), as a cryst. red-brown powder contg. 4 mols. H_2O of crystn. Sodium [dimethylhydroxyglyoxime] nickelate (**XXII**), (like **XIX**), $(\text{C}_2\text{H}_5\text{O}_3\text{N}_2\text{Ni})\text{Na}_2 \cdot 12\text{H}_2\text{O}$, treated with a little AcOH at 100° gives **XXI**, also warming 5 g. $\text{MeC}(:\text{NOH})\text{C}(:\text{NOH})\text{Cl}$ (**XXIII**) in 25 cc. EtOH with 20 g. NaOAc in 50 cc. 50% AcOH for some time at 40–50° and then adding 25 cc. $\text{Ni}(\text{OAc})_2$ and later 20% NaOH to a persistent alk. reaction seps. gradually 4.9 g. **XXII**. From concd. solns. of **XXII** a tetrahydrate $(\text{C}_2\text{H}_5\text{O}_3\text{N}_2\text{Ni})\text{Na}_2 \cdot 4\text{H}_2\text{O}$, seps. Both of these hydrates at 100° give the monohydrate. The corresponding K salt was obtained as a trihydrate and this gave an anhyd. form at 105°. The *NiH*, salt $(\text{C}_2\text{H}_5\text{O}_3\text{N}_2\text{Ni})(\text{NH}_4)_2$ was obtained similarly. **XXIII** treated as above, with $\text{Cu}(\text{OAc})_2$, gave Na [dimethylhydroxyglyoxime] cuprate, $(\text{C}_2\text{H}_5\text{O}_3\text{N}_2\text{Cu})\text{Na}_2 \cdot 7\text{H}_2\text{O}$, and at 100° this gave the anhydride. The K and NH_4 salts were obtained similarly. *NiH*, [dimethylhydroxyglyoxime] cobaltoate, $(\text{C}_2\text{H}_5\text{O}_3\text{N}_2\text{Co})(\text{NH}_4)_2 \cdot 2\text{H}_2\text{O}$, also was obtained.

Reactions of organic thiosulfates. H. B. FOOTNER AND SAMUEL SMILES. *J. Chem. Soc.* 127, 2887–91 (1925).— $\text{RS} \cdot \text{SO}_2 \cdot \text{ONa}$ and NaSR' react quickly at the ordinary temp. to give RSSR' and Na_2SO_3 ; when R and R' are not the same radical, there results in most cases a mixt. of the 2 possible sym. disulfides. The yields generally exceed 95%. $2\text{-O}_2\text{NC}_6\text{H}_4\text{SNa}$ and $\text{PhCH}_2\text{SSO}_2\text{Na}$ give 99% of benzyl 2-nitrophenyl disulfide, yellow, m. 54°. Benzyl 9-anthryl disulfide, yellow, m. 128°. $\text{RS} \cdot \text{SO}_2\text{Na}$ are also quickly decompd. by aq. alkali cyanides, more than 90% reacting to give RSCN . 4-Nitrobenzyl thiocyanate, m. 79°. 9-Anthryl thiocyanate, pale yellow, m. 181°. $(\text{PhCH}_2\text{SO}_2)_2\text{S}$ and RSNa give $\text{PhCH}_2\text{SO}_2\text{SNa}$, $\text{PhCH}_2\text{SO}_2\text{Na}$ and $(\text{RS})_2$. $\text{Na}_2\text{S}_2\text{O}_6$ and RSNa give $(\text{RS})_2$ and $\text{Na}_2\text{S}_2\text{O}_8$, the yield of disulfide being 95–99%. $\text{Na}_2\text{S}_2\text{O}_8$ and RSNa give $(\text{RS})_2$, Na_2SO_3 and $\text{Na}_2\text{S}_2\text{O}_8$, the yields of disulfides again varying between 95 and 100%.

C. J. WEST

Chlorination of tetramethylenic polymers. E. PUXEDDU. *Gazz. chim. ital.* 55, 604–10 (1925).—In earlier work (C. A. 3, 1144; 6, 1136; 7, 1724; 11, 1158; 14, 3066) on the constitution of polymers of phenols having a propenylic side-chain, P. studied

the action of Br_2 on the polymers and found that substitution occurs, showing that these compds. do not contain the propenyl double bond. In this paper results on the chlorination of these polymers are given. It was hoped to gain a better insight into these compds. through these chlorination products but the products are not cryst., do not have a m. p. and do not show any distinctive reactions; they are amorphous yellow to red-yellow powders, insol. in H_2O but sol. in org. solvents, sol. in hot alkali hydroxides and are purified with difficulty. Isoeugenol in EtOH treated with concd. HCl and exposed to the light gave a cryst. ppt. of diisoeugenol (I), m. 180° . 6 g. I in 70 cc. CHCl_3 was treated with Cl gas until no more Cl was absorbed (about 2 hrs.). On evapg. the CHCl_3 a plastic yellow mass was obtained which hardened on standing in the air for some time. This was dissolved in 95% EtOH and was pptd. as a yellow non-homogeneous powder by adding H_2O . Part is sol. in hot ligroin and seps. on cooling; this is *hexachlorodiisoeugenol*, $\text{C}_{20}\text{H}_{18}\text{Cl}_6\text{O}_4$, decomp. about 105° . The insol. part is red-brown and was not analyzed. Chlorination of I in AcOH, in boiling CCl_4 at 76° and in xylene at 140° gave the same hexa- Cl deriv. as was obtained at ordinary temps. I shaken for an hr. with alkali and Me_2SO_4 sepd. dimethyldiisoeugenol (II), m. 106° . II chlorinated in CHCl_3 as with I gave a red-yellow product contg. more than 6 atoms of Cl . Diethyldiisoeugenol (III) was prepd. from $\text{Et}_2\text{SO}_4 + \text{I}$ as with II and when chlorinated in CHCl_3 as above gave the *tetra-Cl deriv.* of III, decomp. 85° . A soln. of isosafrole in dry Et_2O treated with dry HCl gas in the presence of FeCl_3 gave diisosafrole. This chlorinated in CHCl_3 at room temp. as above gave *hexachlorodiisosafrole*, $\text{C}_{20}\text{H}_{14}\text{Cl}_6\text{O}_4$, softens 90° , decomp. 123° .

E. J. WITZEMANN

Rearrangements of benzyl ethers. II. PAUL SHORIGIN *Ber.* 58B, 2028 36 (1925); cf. C. A. 19, 496.—The opinion expressed in the 1st paper that in the rearrangement, $\text{PhCH}_2\text{OR} \longrightarrow \text{PhCH}(\text{OH})\text{R}$, which benzyl ethers undergo under the influence of Na the radical R becomes attached to the central C atom through the same C atom through which it was originally attached to the O has been further confirmed with those ethers where $\text{R} = p\text{-tolyl}$, cyclohexyl and PhCH_2 , while *o*- $\text{MeC}_6\text{H}_4\text{OCH}_2\text{Ph}$ (I) and 2,4- $\text{Me}_2\text{C}_6\text{H}_3\text{OCH}_2\text{Ph}$ (II) gave entirely unexpected results, forming phenols instead of carbinols. Thus, I yielded *o*- $\text{HOC}_6\text{H}_4\text{CH}_2\text{CH}_2\text{Ph}$ (III). Other ethers (Ph , Et) of *o*- $\text{MeC}_6\text{H}_4\text{OH}$ are much more stable towards Na than I and require heating to 260° , and in both cases only the normal decompn. into $\text{PhMe} + \text{ROH}$ and $\text{MeC}_6\text{H}_4\text{OH} + \text{RH}$ occurs, there being no rearrangement, showing that in these cases also the ability to rearrange is dependent on the presence of a PhCH_2 group. Among the reaction products of $\text{PhCH}_2\text{CH}_2\text{OPh}$ and Na no $\text{PhCH}_2\text{CH}(\text{OH})\text{Ph}$ could be detected. PhCH_2SPh undergoes with Na only the normal decompn. into PhMe and PhSH . From 22 g. *p*- $\text{MeC}_6\text{H}_4\text{OCH}_2\text{Ph}$ and Na heated 28 hrs. on the H_2O bath are obtained 1.5 g. PhMe , 3 g. $\text{MeC}_6\text{H}_4\text{CH}(\text{OH})\text{Ph}$, b_{18} $185\text{--}90^\circ$, m. $53\text{--}4^\circ$, and 5.7 g. *p*-cresol. Cyclohexyl benzyl ether, from $\text{C}_6\text{H}_{11}\text{ONa}$ and PhCH_2Cl in boiling C_6H_6 (27 g. from 45 g. $\text{C}_6\text{H}_{11}\text{OH}$), b_{17} 146° , d_4^{21} 0.9856; 20 g. with Na gives PhMe and 4.6 g. $\text{C}_6\text{H}_{11}\text{CH}(\text{OH})\text{Ph}$, b_{12} $152\text{--}7^\circ$, m. $50\text{--}1^\circ$. From 20 g. $(\text{PhCH}_2)_2\text{O}$ are obtained 1.6 g. PhMe , 2 g. PhCH_2OH , 3 g. $\text{PhCH}_2\text{CH}(\text{OH})\text{Ph}$, b. $167\text{--}200^\circ$, m. $62\text{--}3^\circ$, a small amt. of a substance (probably stilbene), m. 124° , and about 0.2 g. BzOH . From 20 g. I, b_{24} 183° , d_4^{20} 1.0601, d_{20}^{20} 1.0528, heated 80 hrs. with Na , are obtained 0.5 g. PhMe , 3.5 g. III, m. $84\text{--}5^\circ$ (mixed with *o*- $\text{MeC}_6\text{H}_4\text{CH}(\text{OH})\text{Ph}$, m. $92\text{--}5^\circ$, it m. 60°), and 3.5 g. *o*-cresol. The same decompn. can be effected in 3.5 hrs. by heating the I and Na in dry H at $200\text{--}50^\circ$. The isomeric 2-methyl-6-benzylphenol, from *o*- $\text{MeC}_6\text{H}_4\text{ONa}$ and PhCH_2Cl , b_{15} $187\text{--}8^\circ$, m. $51\text{--}2^\circ$, sol. in alkalis, dissolves in concd. H_2SO_4 without color. Benzyl 2,4-dimethylphenyl ether (II), from $\text{Me}_2\text{C}_6\text{H}_3\text{OK}$ and PhCH_2Cl (30–5 g. from 35 g. of the phenol), b_{18} $186\text{--}7^\circ$ (cor.), d_4^{20} 1.0455; 20 g. heated 70 hrs. with Na gives 0.6 g. $\text{PhMe} + \text{C}_6\text{H}_4\text{Me}_2$, 2.4 g. 2,4- $\text{Me}_2\text{C}_6\text{H}_3\text{OH}$ and 5.4 g. of a compd. (undoubtedly somewhat impure 3-methyl-6-hydroxydibenzyl), b_{15} $193\text{--}4^\circ$, d_4^{26} 1.060, only partially sol. in alkalis, sol. without color in H_2SO_4 ; phenylurethan, m. $114\text{--}5^\circ$. From the product obtained by heating 19 g. $\text{PhCH}_2\text{CH}_2\text{OPh}$ and Na 70 hrs. in a sealed tube on the H_2O bath were isolated 0.7 g. EtPh , 3.5 g. unchanged ether and 5.2 g. PhOH . *o*- $\text{MeC}_6\text{H}_4\text{OPh}$ (18 g.) and Na heated 6 hrs. at $200\text{--}70^\circ$ gave 0.3 g. $\text{C}_6\text{H}_6 + \text{PhMe}$ and 5.5 g. $\text{PhOH} + \text{cresol}$, the PhOH predominating. *o*- $\text{MeC}_6\text{H}_4\text{OI}$ (24 g.) after 4 hrs. at $240\text{--}65^\circ$ gave inflammable gases ($\text{C}_2\text{H}_2 + \text{C}_2\text{H}_4$), 10 g. unchanged ether and 6 g. *o*-cresol. PhCH_2SPh , m. $41.5\text{--}2.0^\circ$, b_{27} 197° (cor.); 20 g. heated 36 hrs. with Na gives 0.7 g. PhMe , 4 g. PhSH and a residue smelling faintly of S compds., which in Et_2O did not decolorize I-KI .

C. A. R.

The peroxides of aldoximes. III. R. CIUSA AND E. PARISI. *Gazz. chim. ital.* 55, 416–21 (1925); cf. C. A. 17, 2570; 18, 821.—The formula, RCH:N.O.O.N:CHR for the peroxides of aromatic aldoximes (I) has been accepted without question. It explains

most of the properties of these compds. but it does not explain for instance why peroxides of the ketoximes do not exist. It is necessary to note that the various products obtained in the spontaneous decompn. of I (Robin, *C. A.* 15, 3469; Parisi, *C. A.* 19, 49) or by heating or recrystg. in solvents are of 2 kinds: monomol. and bimol. The 1st are the unchanged aldoxime, hydroxamic acid, phenylnitromethane, nitrile, aldehyde and CO_2H acid. The 2nd or bimol. products are furazan, dibenzenyloxime, α - and β -dibenzenylosazoxime (II and III) (Parisi, *C. A.* 18, 1297). Both kinds of products always accompany the formation of the peroxides. From the available facts C. and P. are convinced that I may be a mol. compd. of the unchanged oxime with the nitrile oxide. The formation of II from PhCH:N.O O N:CHPh observed by R is difficult to explain by the old formula, but if I is considered to be $\left[\begin{smallmatrix} \text{R.CH:NOH} \\ \text{R.C N:O} \end{smallmatrix} \right]$, this reacting with O would give 2 RC:N:O and II, i. e. RC:N(O) O.CR:N , finally. The peroxide of PhCH:NOH on reduction gives the oxime, the nitrile, BzOH and BzNH_2 according to the reaction: $\left[\begin{smallmatrix} \text{PhCH:NOH} \\ \text{PhC:N:O} \end{smallmatrix} \right] + \text{H}_2 \rightarrow \text{PhCH:NOH} + \text{PhC:N} + \text{H}_2\text{O}$. This also confirms the new formula for I. Some other data and arguments are given

E. J. WITZEMANN

Photochemical reactions in the series of *o*-nitrobenzylidene acetals. IOAN AND HELENE TĂNĂSESCU. *Bul. soc. stiinte Cluj* 2, 369-82 (1925). T. and T. study the action of sunlight on *o*-nitrobenzylideneglycol, $\text{O.CH}_2.\text{CH}_2.\text{O.CHC}_6\text{H}_4\text{NO}_2$ (I), (b_{12} 171°),

and *di-o* nitrobenzylidene-erythritol, $\text{O}_2\text{NC}_6\text{H}_4\text{CH.O.CH}_2.\text{CH.O} \left[\begin{smallmatrix} \text{O} \\ \text{O} \end{smallmatrix} \right] \text{CH.CH}_2.\text{O.CH}.\text{C}_6\text{H}_4\text{NO}_2$, (II) (cf. *C. A.* 19, 2932) (*amphi*-form, m. 193° and *anti*-form, m. 238°) Heating *o*- $\text{O}_2\text{NC}_6\text{H}_4\text{CHO}$ with the dried glycol in a closed tube produces I. According to Sachs and Hilpert (cf. *Ber.* 37, 3425) the group *o*- $\text{NO}_2\text{C}_6\text{H}_4\text{CH}$ should be light-sensitive. This is confirmed. Insolation of I yields an isomer, *o*- $\text{NOC}_6\text{H}_4\text{C(OH).O.CH}_2.\text{CH}_2.\text{O}$

(III), which forms white crystals, m. 128°, to a green melt or soln. III hydrolyzes easily on boiling with acid or base, giving glycol, and *o*- $\text{ONC}_6\text{H}_4\text{CO}_2\text{H}$. It has no primary alc. group. The *amphi*-form of II yields readily on insolation

o- $\text{ONC}_6\text{H}_4\text{C(OH).O.CH}_2.\text{CH.O} \left[\begin{smallmatrix} \text{O} \\ \text{O} \end{smallmatrix} \right] \text{CH.CH}_2.\text{O.CHC}_6\text{H}_4\text{NO}_2$. The

latter gives a mono-Bz deriv., m. 92-3°, and hydrolyzes, with *N* NaOH to $\text{HOCH}_2\text{CH(OH)CH.O.CH(C}_6\text{H}_4\text{NO}_2\text{).O.CH}_2$, m. 114°. The *anti*-form of II is almost

insensitive to light and evidently undergoes an isomerization before reacting photochemically.

D. S. VILLARS

The polymerization of derivatives of cinnamylideneacetophenone. MICHELLE GUJA. *Gazz. chim. ital.* 55, 567-76 (1925).—This is a continuation of earlier work (*C. A.* 16, 557) on the influence of the NHCOMe group on the polymerization of derivs. of PhCH:CHCH:CHCOPh (I). 20 g. *m*- $\text{O}_2\text{NC}_6\text{H}_4\text{COMe}$ (II) in 200 cc. EtOH agitated with 16 g. $\text{PhCH:CHCHO} + 10$ cc. 15% NaOH sepd. presently *cinnamylidene-m-nitroacetophenone* (III), yellow, m. 135-6°. 3 g. III in dry CHCl_3 with 10% Br_2 in CHCl_3 after standing was treated with an equal vol. of petroleum ether; *tetrabromotetrahydrocinnamylidene-m-nitroacetophenone*, yellow, m. 203-4° (decompn.), sepd. 1.6 g. II treated as with III with *p*- $\text{McOC}_6\text{H}_4\text{CH:ClCHO}$ gave *p-methoxycinnamylidene-m-nitroacetophenone*, yellow, m. 157-8°. A 10% soln. of III in CHCl_3 was insolated 15 days in a sealed flask and gave on evapn. a semisolid tar that hardened on standing. The resinification also occurred on exposing the soln. in a quartz tube for 12 hrs. to the rays of an ultra-violet lamp. No indications of the formation of a dimer were observed. I is also easily resinified but not so easily as to interfere with obtaining the dimeric form. The presence of the NHCOMe group and NO_2 in the aromatic ring favors resinification. These groups are called resinophors (Gibner, *C. A.* 17, 3796). A no. of binary equil. curves were detd. In the system I-*o*- $\text{ClC}_6\text{H}_4\text{NO}_2$ a eutectic is formed that solidifies at 25.8° at a concn. of 24% I by wt. The eutectic with I-*p*- $\text{ClC}_6\text{H}_4\text{NO}_2$ solidifies at 54.8° at a concn. of 43% I; with I-*p*- $\text{BrC}_6\text{H}_4\text{NO}_2$ the eutectic comes at 60% I and solidifies at 74°. In the system I-*m*- $\text{C}_6\text{H}_4(\text{NO}_2)_2$ an addn. complex is formed at 48.15% I which is strongly dissociated in the fused state

and m. 59°. In I-1,2,4-BrC₆H₃(NO₂)₂ an equimol. addition complex (IV) is formed that m. 90°; the eutectic between IV and BrC₆H₃(NO₂)₂ solidifies at 61.2° and that between I and IV solidifies at 84.7°. In the system I-*p*-NH₂C₆H₄COMe a eutectic exists at 53% I and solidifies at 72.5°. In the system I-thymoquinone a eutectic exists at 25% I that solidifies at 37.4°. I forms addn. compds. with polynitro compd. only, as is shown in earlier work (C. A. 11, 1141) E. J. W.

Synthesis of ephedrine. E. FOURNEAU AND C. TORRES. *Anales soc. españ. fís. quim.* 23, 450-6(1925).—The action of MeNH₂ on PhCOCHBrMe, followed by reduction of the aminoacetone obtained, gives two bases: one m. 117° and its HCl salt, m. 164°, and is the Späth pseudo-ephedrine (C. A. 15, 1016); the other m. about 60° and its HCl salt m. about 190°. This latter base, according to Späth, does not correspond to *dl*-ephedrine, m. 73°. A base of exactly the same properties was obtained by Emde (C. A. 6, 866) and by Fournéau and Puyal (C. A. 17, 2418) by reducing PhCH-(NHMe)COMe. Although the identity of these NH₂ alcs. is established there are anomalies hard to explain. E. M. SYMMES

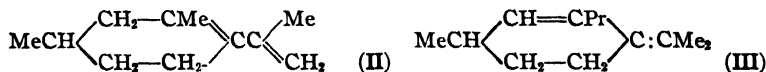

Action of hydrazine upon nitro and chloronitro derivatives of benzene and naphthalene. I. ERNST MÜLLER. *J. prakt. Chem.* 111, 273-6(1925).—General introduction II. Action of hydrazine hydrate upon several nitro and chloronitro compounds. E. MÜLLER AND GEORG ZIMMERMANN. *Ibid* 277-92.—*m*-O₂NC₆H₄CO₂H and N₂H₄·H₂O (I) in EtOH give the *hydrazine salt* of the acid, m. 182°; heating the salt with more I on the H₂O bath for 0.5 hr. gives *m*-H₂NC₆H₄CO₂H. The *p*-O₂NC₆H₄CO₂H behaves similarly. *o*-, *m*- and *p*-O₂NC₆H₄Me give nearly theoretical yields of the NH₂ derivs. when heated with I in a sealed tube 4 hrs. at 130°. The 3 O₂NC₆H₄NH₂ and I at 150° for 4 hrs. give the corresponding C₆H₄(NH₂)₂. 2,4-(O₂N)₂C₆H₃Me and I heated 6 hrs. on the H₂O-bath give the 4-NH₂ deriv., which, heated with more I at 140° gives 2,4-(H₂N)₂C₆H₃Me. *m*-ClC₆H₄NO₂ and I at 100° give 84% of *m*-ClC₆H₄NH₂. *o*-ClC₆H₄NO₂ and I, boiled 4 hrs., give 88% of benzeneazimidole, m. 156°, whose *hydrazine salt*, m. about 110-20°. 2,4-Cl₂C₆H₃NO₂ and I give 89% of the *hydrazine salt*, m. 182-3° (decompn.), of 4-chlorobenzeneazimidole, explodes 204-5°; this is a strong acid and liberates CO₂ from carbonates; the *K* salt explodes when heated above 300°. *Et ester*, m. 59-60°; *Bz deriv.*, m. 126°. The following derivs. of 5,2,4-Cl(O₂N)₂C₆H₂NHNH₂ are described: *Benzal*, orange, m. 242°. *Acetone*, yellow, m. 123°. *Acetoacetic ester condensation product*, m. 115°. *HCHO condensation product*, yellow, m. 124°. *Bz deriv.*, reddish yellow, m. 219°. *NO deriv.*, yellow, decomp. 85°; decompn. in 50% AcOH gives 2,4,2',4'-tetranitro-5,5'-chloroazobenzene, yellow, m. 93°; on further heating it explodes with a yellow vapor; mol. wt. in boiling C₆H₆ 342.5. 2,4,1,5-(O₂N)₂C₆H₂-(NHNH₂)₂ forms a *HCl salt*, light yellow, decompd. by H₂O, a *sulfate*, yellow, decomp. 213° and a *Bz deriv.*, orange-yellow, m. above 300°. III. Action of hydrazine hydrate on 2,4,5-trichloronitrobenzene. E. MÜLLER AND WALTER HOFFMANN. *Ibid* 293-306.—2,4,5-Cl₃C₆H₂NO₂ and I in EtOH give a very poor yield of 3,4-dichloro-6-nitrophenylhydrazine (II), orange-yellow, m. 194.5°; *benzal compd.*, yellow-red, m. 184°; *o*-hydroxybenzal deriv., greenish yellow, m. 207°. *m*-Dihydroxybenzal deriv., orange-red, m. 251°; *acetone compd.*, citron-yellow, m. 157°; *benzophenone compd.*, light yellow, m. 162°. II and HNO₂ (NaNO₂ and HCl) give 3,4-dichloro-6-nitrodiazobenzeneimide, yellow-brown, m. 56°. 2,4,5-Cl₃C₆H₂NO₂ and I in EtOH, heated 3 hrs. on the H₂O-bath, give the *hydrazine salt*, m. 205° (decompn.), of 4,5-dichlorobenzeneazimidole (III), decomp. 194-6°; *K salt*, decomp. explosively at 230-50°; *Ba salt*, needles, explodes on heating or on treating with concd. H₂SO₄; *Mg salt*; Cu salt, green needles; *Ag salt*, darkens in the light and explodes upon heating. *Aniline salt*, m. 168° (decompn.). *Me ether*, m. 129°; *Et ether*, m. 90°. *Bz deriv.*, m. 152°. *Ac deriv.*, m. 150°. *Et acetate deriv.*, m. 109°. *Et formate deriv.*, m. 123°. 2,4,5-Cl₃C₆H₂NO₂ (22 g.) and 5 g. N₂H₄ give 0.6 g. 2,3-dichloro-6-nitrophenylhydrazine, red, m. 172°; *HCl salt*, yellow, m. 195° (decompn.), hydrolyzed by hot H₂O; *benzal compd.*, red, m. 225°. II dissolves in aq. NaOH with a violet color; heating with concd. alkali gives a brown smeary mass, a little III being isolated from the filtrate. II and I give III. IV. Action of hydrazine upon 1-chloro-2,4-dinitronaphthalene. E. MÜLLER AND KARL WEISBROD. *Ibid* 307-12.—2,4-(O₂N)₂C₁₀H₆Cl and I in EtOH, warmed 6 hrs. on the H₂O bath, give a mixt. of 4,4'-dinitro-2,2'-azonaphthalene (IV), brown-red, m. 315°, the *di-NH₄ salt* of 2,4-C₁₀H₆-(NO₂)₂ (V), red, m. 203-5°, *m*-nitronaphthylazimidole, yellow, m. 215° and some V. The reaction in the cold gives the same products. Anhyd. N₂H₄ gives IV and V. C. J. WEST

Relationship between the optical rotatory powers and the relative configurations of optically active compounds. II. The relative configurations of the optically active mandelic acids and β -phenyllactic acids. G. W. CLOUGH. *J. Chem. Soc.* 127, 2808-12

(1925); cf. *C. A.* 12, 2188.—From published data on the ~~not~~ rotations of optically active α -HO acids and their derivs., it is concluded that ~~hexahydromandelic and mandelic acids belong to the "d" series of α -HO acids as probably does d - β -phenyllactic acid.~~ *l*-Mandelic acid, $[\alpha]^{14}_{D} -158^{\circ}$, -166° , -188° , -426° for $c = 5.893, 5.780, 5.661, 4.078$ (this order used below) (in H_2O , c 1.59); $[\alpha]^{14}_{5461} -203^{\circ}$ (4 *N* NaCl, c 1.59). Et ester, d_4^{15} 1.128, $[\alpha]^{15}_{D} -129.4^{\circ}$, -135.7° , -156.4° , —; $[\alpha]^{15}_{D} -117.4^{\circ}$, -121.9° , -141° , -325° (in MeOH, c 10); $[\alpha]^{15}_{D} -149.6^{\circ}$, —, -180.5° , — (N MeOH-NaBr, c 10.12). *Me l*-phenylbenzoyloxyacetate, b_{18} 224–5°, d_4^{20} 1.217, $[\alpha]^{20}_{D} -141.4^{\circ}$; *Me l*-phenyllactate, d_4^{20} 1.129, $[\alpha]^{20}_{D} -4.74^{\circ}$. *Me d*- α -acetoxy- β -phenylpropionate, b_{20} 185°, m. 30–1°, d_4^{18} 1.125°, $[\alpha]^{18}_{D}$ 7.33°. *Me l*- α -benzoyloxy- β -phenylpropionate, b_{18} 224–5°, d_4^{20} 1.161, $[\alpha]^{20}_{D} -32.45^{\circ}$. C. J. WEST

Reaction of lactoses with aromatic hydrocarbons and aluminium chloride. E. J. KING. *Trans. Roy. Soc. Can. Sec. III* (3) 19, 29(1925).—Phthalide gave only *o*-PhCH₂-C₆H₄CO₂H. Diphenylphthalide gave no reaction. Phthalide with C₁₀H₈ in C₆H₆ reacts only with C₆H₆. In CS₂ C₁₀H₈ with phthalide and with phenylphthalide gave only β -C₁₀H₇ derivs. Coumarin with C₆H₆ and AlCl₃ gave a very little of a product, m. 82°, which with Br in the cold gave a product m. about 112°. J. W. S.

The constitution of pulegone, of tertiary alkylpulegols and of alkylpulegenes. V. GRIGNARD AND J. SAVARD. *Compt. rend.* 181, 589–92(1925).—It is already known that pulegone (I) and MeMgI give a methylpulegol which on dehydration yields a hydrocarbon of doubtful compn. (cf. Grignard, *Ann. chim. phys.* 24, 433(1901); Rupe, *C. A.* 2, 2384; Auwers and Eisenlohr, *C. A.* 4, 1745). This problem was studied further with the aid of a more recent method of G. (*C. A.* 18, 659). Contrary to previous belief, I is not a single compd., but a mixt. of the β -form of I and 15–8% isopulegone (α -form). Org. Mg compds. do not alter this equil., so that the tertiary β -pulegols and α -pulegols are in the same proportion. Instead, however, of hydrocarbons of corresponding form being obtained on dehydration, partial isomerization of the β - to the α -form occurs. The hydrocarbons from 4 pulegols gave on ozonization the following proportions of Me₂CO and HCHO + HCO₂H, resp.: Me, 28, 68; Pr, 77, 24; Bu 45, 50; iso-Pr 56, 43. It is concluded that the double bond created by dehydration is intranuclear, and not semicyclic. A study of the position of the double bond in the ring showed that it was probably conjugate, methyl- α -pulegone having the compn. II, which cannot give the

β -form. On ozonizing the β -form of propylpulegene and decomp. the ozonide with H₂O, the chief product was α -methylglutaric acid, indicating that β -forms of such compds. have the compn. exemplified by III. In general the alkylpulegenes are mixts., in varying proportions, of the α - and β -forms, the origin if not the proportions of which depend on the natural pulegone itself. In both series the double bonds are conjugate, from which arises the unexplained anomaly of an absence of any increase in mol. refraction. C. C. DAVIS

Menthone series. I. JOHN READ AND ALISON MARY RITCHIE COOK. *J. Chem. Soc.* 127, 2782–8(1925).—*dl*-Piperitone, reduced with EtONa, gives about 9% of *dl*- α -phellandrene and 42.4% of liquid and solid menthols. The fraction b_{10} 95–7° (410 g.), on oxidation with CrO₃, gave 332 g., 37% of which b_8 82°, n_D^{17} 1.4553, $\alpha_D^{17} -0.18^{\circ}$ and 40% b_8 82–5°, n_D^{17} 1.4571, $\alpha_D^{17} -0.34$, the latter consisting essentially of *dl*-isomenthone. Further reduction of the isomenthone fraction with EtONa gives a mixt. of *dl*-menthol (and *dl*-isomenthols), which was further oxidized to *dl*-menthone. Catalytic reduction of piperitone gave as the main fraction *dl*-isomenthone, which was converted as above to *dl*-menthone. *dl*-Isomenthone oxime, m. 99–100°, anorthic crystals with forms *a*, *m*, *M*, *c*, *Q*, and rarely *O*; *a*:*b*:*c* = 2.049:1:2.281, α 112°12', β 116°17', γ 86°57'; optical extinction is nearly straight with the vertical edge and an optic axis lies just within the field. *B β* deriv., m. 55.5°. *dl*-Isomenthone isoöxime, m. 94–5°. *Benzoyl-dl*-menthone oxime, m. 72–3°. *dl*-Menthone isoöxime, m. 114–5°. *dl*-Menthone gives a small amt. of a α -semicarbazone, m. 185–6°, but principally the β -deriv., m. 161–2°. *dl*-Menthone and *dl*-isomenthone may most readily be discriminated by prep. the oximes or semicarbazones in weakly acid soln. C. J. WEST

Aluminium oxide as a condensing agent and the role of carrier substances in the catalysis. K. W. ROSENMUND AND A. JORTHE. *Ber.* 58B, 2054–8(1925).—The object

of the present work was to det. whether Al_2O_3 can act as a condensing catalyst in a liquid medium. In high boiling solvents, it can bring about the condensation of PhCH_2OH with amines, with elimination of H_2O . The reaction is already marked at 170° , and in tetralin or PhNO_2 70–85% yields can be obtained. Both Al_2O_3 obtained by dehydrating $\text{Al}(\text{OH})_3$ at 400° and the com. article were used; the efficiency of the latter was variable. The favorable influence of Al_2O_3 in certain catalytic reactions is probably due to this property it has of effecting dehydrating condensations, as already suggested by Ipat'ev in the case of the reduction of borneol to isocamphane (*C. A.* 7, 2187), but R. and J. do not believe that his assumption of the formation of a labile complex $\text{Al}_2\text{O}_3 \cdot \text{NiO}$ is sufficiently general; a more satisfactory explanation is the assumption of "com-

plex" formation between the catalyst and the 2 reacting substances:

$$\begin{array}{c} \text{C}_{10}\text{H}_{17} \cdots \text{H} \\ \diagdown \quad \diagup \\ \text{[Al}_2\text{O}_3\text{]} \\ \diagup \quad \diagdown \\ \text{Ni} \\ \diagdown \quad \diagup \\ \text{HIO} \cdots \text{H} \end{array}$$

Borneol and H_2 are bound to the catalyst by partial affinities (adsorption), and the inner forces of the mol. are consequently loosened and the conditions prerequisite for the regrouping of the forces are established. The HO of the borneol tends towards I, the borneol residue towards the other atom of the H_2 mol. and the whole breaks down into H_2O , the reaction product and the catalyst. The Al_2O_3 plays a double role; by its marked adsorptive power it brings the borneol to the catalyst and, secondly, it eliminates H_2O from the labile complex. The reduction therefore seems to be a condensation between ROH and H_2 , the Ni effecting the loosening between the atoms of the H_2 and the Al_2O_3 , the elimination of the H_2O . Other substances, like ThO_2 and TiO_2 , show in principle the same phenomena as Al_2O_3 . C. A. R.

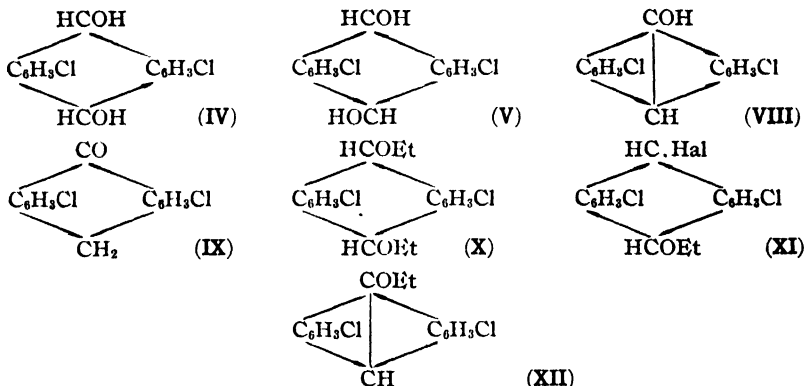

Recent researches on sesquiterpenes. RAGNAR VESTERBERG. *Svensk Kem. Tids.* 37, 219–26(1925).—The work of Ruzicka in developing the structural formulas of cadalene and selenene is traced step by step. Tests of samples contg. sesquiterpenes are given briefly. These will be published in the *Ann* A. R. ROSE

Benzidine derivatives of thiourea. LEÓN PINTO. *Compt. rend.* 181, 788–90 (1925)—A low yield of monoacetylbenzidine (I) is obtained by condensing benzidine with 10 parts of glacial AcOH at 130° for 3 hrs. I is treated with an excess of CS_2 in EtOH for 20 hrs. on the water bath to form diacetylbenzidinethiourea (II), m. above 360° . The free base (III) is obtained by hydrolyzing at $125\text{--}130^\circ$ with 0.1 N HCl III at 70° loses its water of crystn. Diazotizing and coupling III with aromatic amines and phenols gives a new series of direct cotton colors. D. H. POWERS

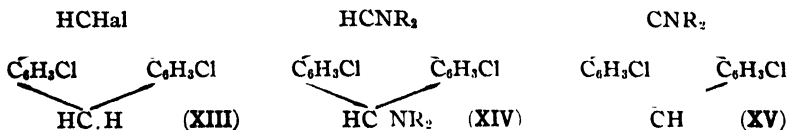

Methylation of the oximes of benzil. O. L. BRADY AND HILDA M. PERRY. *J. Chem. Soc.* 127, 2874–82(1925).— γ -Benzil oxime in NaOH and Me_2SO_4 give a mixt. of the *N*-Me ether, m. $109\text{--}10^\circ$, which is less sol. in ether-petroleum ether than the isomeric *O*-Me ether (I), m. 63° (cf. Dittich, *Ber.* 23, 3589(1890)). Me detns. on the *O*-Me ether gave consistently low results in the presence or absence of Ac_2O . α -Benzil oxime gave only the *O*-Me ether, m. $58\text{--}9^\circ$, which is transformed into I by heating 30 min with concd. HCl. α -Benzil dioxime and Me_2SO_4 give the *N,N*-di-Me ether, m. 192° (decompn.); it crysts from C_6H_6 with 0.5 C_6H_6 , m. 185° and from EtOH with 0.5 EtOH(?), m. $165\text{--}6^\circ$; it is sep'd by its insoly. in Et₂O. The mother liquor, purified through the HCl salt, gives the *N*O-Me ether, m. 109° (cf. Auwers and Meyers, *Ber.* 21, 3510(1888)); with concd. HCl this gives I. The *O,O*-di-Me ether was prep'd. from the oxime, Ag_2O and EtI in dry Et₂O; it m. $163\text{--}4^\circ$ and on heating with concd. HCl gives the β -deriv. β -Benzil dioxime and Me_2SO_4 give a mixt. of the *N,O*-di-Me ether, m. $102\text{--}3^\circ$, transformed by concd. HCl to I, and the *O,O*-di-Me ether, m. $72\text{--}3^\circ$. Methylation of γ -benzil dioxime gave only I, which suggests that the *N,N* and *N,O*-di-Me ethers are formed but very readily hydrolyzed. C. J. WEST

The mechanism of substitution reactions in the aromatic nucleus. III, IV. E. DEB. BARNETT, J. W. COOK AND M. A. MATTHEWS. *Rec. trav. chim.* 44, 728–39, 818–26(1925) (In English); cf. *C. A.* 19, 2488.—In a previous paper (B. and M., *C. A.* 19, 59) it was shown that 1,5-dichloroanthracene dibromide (I) probably has the *cis*-configuration, since on thermal decompn. it loses Br and gives 1,5-dichloroanthracene (II) almost quant. The stability of the corresponding dichloride (III) (Liebermann, Beudet, *C. A.* 8, 2159) pointed to its having the same configuration and this has now been proved by its thermal decompn. into II. The yield from II is poorer than from I. KOH-EtOH acting on III gives not over 50% of 1,5,9-trichloroanthracene. These facts suggest that III is a mixt. of isomers or that the *cis*- is readily converted into the *trans*-form under some conditions. The latter is more probable since III is crystd. unchanged from boiling xylene and no isomer has been obtained by this method. I and II have now been investigated more fully. The results show that generally both

react as if they were *cis*-forms but sometimes a partial conversion into a *trans*-compd. seems to take place. This conversion is particularly well marked in hydrolytic reactions. If I and III are hydrolyzed by boiling with $\text{H}_2\text{O}-\text{Me}_2\text{CO}$ in the presence of excess CaCO_3 , MgCO_3 or MgO a mixt. of *cis*- and *trans*-dichlorodihydroanthraquinols (IV and V), II, 1,5-dichloroanthraquinone (VI) and 1,5,11,5'-tetrachlorodianthrone $\text{CO}-(\text{C}_6\text{H}_3\text{Cl})_2\text{CHCH}(\text{C}_6\text{H}_3\text{Cl})_2\text{CO}$ (VII) is formed. Of IV and V only the *trans*-isomer

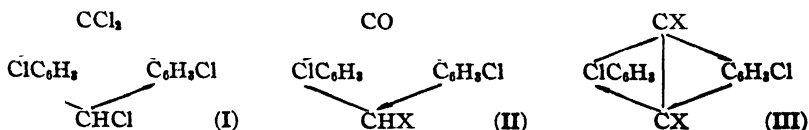

(V) shows any tendency to lose H_2O ; V when heated with KOH or in $\text{H}_2\text{O}-\text{Me}_2\text{CO}$ with a little halogen acid gives the anthranol (VIII) isolated as dichloroanthrone (IX). The formation of VI and VII is due to the oxidation of VIII. This oxidation takes place at the expense of some of the dihalide, which is reduced to II, some of which is always formed. The oxidizing action is thought to be due to nascent halogen formed in the reaction. HBr or HCl acting on IV or V gave dihalides identical with I and III, which with CaCO_3 in $\text{H}_2\text{O}-\text{Me}_2\text{CO}$ gave a mixt. of IV and V. In this way, the change of configuration was demonstrated. IV and V have the same compn. and mol. wt. and both give a diacetate with Ac_2O and a diurethan with PhNC . The *trans*-isomer is less sol., and has the higher m. p. and does not free I from HI in the cold like the *cis*-isomer. When I and III are sapon. by boiling in EtOH a mixt. of mainly dichlorodihydroanthraquinyl di-Et ether (X) and dichloroanthranyl Et ether (XII) is formed. XII is probably formed from a compd. having the *trans*-form and since V is so stable it is not likely that its di-Et deriv. is the intermediate stage. The change of configuration occurs in the I and II used or in an intermediate like XI. Sapon. of II with other alcs. (Pr-, iso-Pr, *n*-Bu, iso-Bu and iso-Am) gave only the homologs of XII and none of X. Only the Pr, *n*-Bu and iso-Am derivs. were purified; the others were viscous oils which were identified by their easy sapon. with AcOH + a little H_2SO_4 to give IX. III boiled 6 hrs. with *tert*-BuOH was recovered unchanged. I reacts with PhOH giving II, which is a typical reaction for the *cis*-form. III behaves differently, giving 1,5-dichloroanthranyl Ph ether and this reaction must be accompanied by a change in configuration. Other phenols (*o*-, *m*- and *p*-cresol, *p*- $\text{ClC}_6\text{H}_4\text{OH}$ and β -naphthol) appear to behave similarly. Thymol reacts with difficulty. The Et and Me homologs of XII are easily sapon. in AcOH and mineral acid (cf. B., C. and M., C. A. 17, 3503; Krollpfeiffer, C. A. 18, 1124). The aryl ethers are more stable but are easily decompd. by HI in AcOH : II is formed and the probable mechanism of this reaction is discussed. It was previously shown (B., C. and M., C. A. 19, 2488) that in many of their reactions the anthracene dihalides and their *bz*-substitution products show a tendency to undergo a change of geometrical configuration, and that in *trans*-isomers the tendency for re-establishment of the "bridge" is considerably greater than in the *cis*-isomers. In this paper, the behavior of I and III with org. bases is described. In this case different reactions were found: (a) a loss of halogen with the formation of II; (b) a change of configuration and loss of halogen acid with production of 1,5,9-trihaloanthracene

(XIII); (c) replacement of both halogen atoms by substituted amino groups (XIV); (d) replacement of 1 halogen atom by a substituted NH_2 group, change of configuration and loss of halogen acid, giving (XV). Of these (a) and (c) must be regarded as "cis-reactions" and (b) and (d) as "trans-reactions." II frequently accompanies other products obtained by the action of bases on I and III and especially when I is used. It is the only isolable product of the action of Ph_2NH , EtNH_2 , PhNMe_2 , α -picoline and quinoline on I. With III loss of halogen takes place less readily and treatment with PhNMe_2 gives mainly 1,5-dichloro-9,10-tetramethyldiaminodiphenyl-9,10-dihydroanthracene, m. 175° (decompn.). XIII is rarely if ever the sole product of the action of a base on I or III but it is the main product when III in boiling xylene is treated with excess piperidine or quinoline. This tendency of bases to cause loss of halogen rather than loss of halogen acid is regarded as an argument in favor of the *cis*-structure of the dihalides I and III. Reaction (c) represents the usual action of primary aromatic amines or secondary aliphatic or aromatic amines on I and III and in many cases the same products are obtained by the action of aromatic amines on 1,5-dichloro-9,10-dihydroanthraquinylidipyridinium dibromide. In this respect I and III differ from the corresponding anthracene derivs (cf. B and C., C. A. 15, 2869; B., C. and M., C. A. 19, 2488). The XIV derivs. are regarded as having the *cis*-configuration since they show little tendency toward reestablishment of the "bridge," e. g. by boiling with EtOH-HCl . Their formation from I and III is a simple replacement of halogen atoms but their formation from the dipyridinium salt must involve a change of configuration, since the ease with which these pyridinium salts lose a mol. of $\text{C}_6\text{H}_5\text{N.HX}$ with the reestablishment of the "bridge" points to their having the *trans*-configuration. This behavior is discussed. The formation of anthranilamine derivs (XV) (*trans*-type of reaction) by the action of bases on I and III has only been demonstrated in the case of $m\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$, in which the product was found mixed with II, showing that both *cis*- and *trans*-reactions had taken place. Tertiary bases in which nuclear reactions are excluded (NEt_3 , NPr_3 , N -methylpiperidine) do not as a rule react with I, although α -picoline and quinoline cause loss of Br and the formation of II; NH_2Me and Ph_2NH behave similarly. The following other new compds. are described. 1,5-Dichloro-9,10-tetraethyldiamino-9,10-dihydroanthracene, m. 130° ; 9,10-dipiperidino deriv., m. 195° ; 9,10-dianilino deriv., m. 211° ; 9,10-dimethylanilino deriv., m. 230° ; 9,10-tetramethyldiaminodiphenyl deriv., does not m. below 300° ; 1,5-dichloroanthranylaniline, yellow, m. 177° ; *o*-toluidine deriv., yellow, m. 189° ; *m*-nitroaniline deriv., yellow, m. 268° . With $\text{C}_6\text{H}_5\text{N}$, III gave 1,5-dichloro-9,10-dihydroanthraquinyl-9,10-dipyridinium dichloride, which with NH_4OH added to its cold H_2O solns. gives 1,5-dichloroanthranylpyridinium chloride, yellow, m. 330° (decompn.). With SO_2 , H_2S (passed through the glacial AcOH soln. at 100°), with Na_2S (in boiling $\text{H}_2\text{O-EtOH}$), with $\text{AcCHNaCO}_2\text{Et}$ and $\text{CHNa}(\text{CO}_2\text{Et})_2$ (both in boiling Et_2O) and with PhMgBr (in boiling abs. Et_2O) I is reduced to II. Et_3S and Mg failed to react with I. C_6H_6 (+ AlCl_3) gave a tar with I. I in EtOH suspension with concd. aq. KCN heated 2 hrs. on the H_2O bath gave 1,5-dichloroanthronitrile, yellow, m. $230\text{--}42^\circ$.

E. J. WITZEMANN

The mechanism of substitution reactions in the aromatic nucleus. V. E. DE BARRY BARNETT, J. W. COOK AND M. A. MATTHEWS. *Rec. trav. chim.* 44, 894-9(1925). (In English.)—In previous papers (C. A. 19, 59, 2488; preceding abstract), it was shown that the tendency for reestablishment of the "bridge" to take place when *meso*-halogen derivs. of 9,10-dihydroanthracene undergo reaction depends on the configuration of these halogen derivs. and on their tendency to undergo change in configuration during the course of the reaction. In the case of 1,5,9-trichloroanthracene dichloride (I) geometrical isomerism is no longer possible and some of its reactions were studied.

2 types of reaction occur: (1) reactions in which 1 halogen atom is replaced by a new group and the remaining 2 by an atom of O, giving a *meso*-substituted anthrone (II); (2) reactions in which 2 halogen atoms on different C atoms are replaced by new groups with simultaneous reestablishment of the "bridge" by loss of HCl , the product being a 9,10-substituted anthracene deriv. of the general formula III ($\text{X} = \text{OH}$, alkoxyl or substituted NH_2 group). H_2O , EtOH , NaOAc , Et_3NH and piperidine react mainly according to (1) and PhNH_2 , MeNHPh and Me_2NPh react according to (2). The *gem*-

Cl_2 group is the more reactive and hydrolysis with aq.- Me_2CO gives first 1,5,9-trichloroanthrone (IV) and subsequently 1,5-dichloro-9-hydroxyanthrone. The action of KOH - EtOH on I leads to 1,5,9,10-tetrachloroanthracene (V) and since in the dichloride there must be a Cl atom in the same plane as the H atom it was expected that the action of heat would lead to reestablishment of the "bridge" by the loss of HCl . But this does not occur in boiling *p*-cymene; IV is almost the sole product. This curious reaction is difficult to explain and throws doubt on the reliability of reactions of this type for detg. geometrical configuration. The question is to be investigated. Although 1,5,9-trichloroanthracene (VI) adds Cl_2 easily in CCl_4 the reaction with Br_2 is much slower and less certain and is accompanied by the evolution of HBr . No definite additive compd. could be isolated; the crude product treated with $\text{C}_6\text{H}_5\text{N}$ gave a little 1,5,9-trichloro-9-bromoanthracene but the prepn. was very uncertain. Although V is easily obtained as described above it is not obtained by the action of SOCl_2 on either 1,5-dichloroanthracene or 1,5,9-trichloroanthracene; both are recovered unchanged. 35 g. VI was ground to a thin cream with 50 cc. CCl_4 and 150 cc. CCl_4 contg. 9% Cl by wt. was added; after standing overnight I was filtered; recrystd. from H_2O - Me_2CO it m. 162° (decompn.). 14 g. I was boiled 0.5 hr. with 150 cc. abs. EtOH contg. 7 g. KOH in 15 cc. H_2O ; V was filtered off and recrystd. from $\text{C}_6\text{H}_5\text{N}$ and MeCOEt ; it m. 195° and on oxidation with CrO_3 gives 1,5- $\text{Cl}_2\text{C}_6\text{H}_3(\text{CO})_2\text{C}_6\text{H}_3\text{Cl}$. V with much Cl in CCl_4 was recovered unchanged after 24 hrs. I heated on the H_2O bath with twice its wt. of Pr_3N gave some V. 5 g. I, 5 g. pptd. CaCO_3 , 12.5 cc. H_2O and 50 cc. Me_2CO were refluxed 1 hr., filtered hot and dild. with H_2O until crystn. began. The product was IV. 5 g. II + 10 g. NaOAc + 40 cc. glacial AcOH heated 15 min., sepd., 1,5-dichloroanthronyl acetate, m. 177° . 5 g. I boiled with 100 cc. abs. EtOH for 1 hrs. gave 1,5-dichloroanthronyl *Et* ether, m. 159° ; when heated with HCl in EtOH it gives IV. 7 g. I in 50 cc. hot C_6H_6 + 7 cc. Et_3NH in 25 cc. C_6H_6 after several days at room temp. gave 1,5-dichloro-9-diethylaminoanthrone, m. 194° . 1,5-dichloro-9-piperidinoanthrone, m. 239° , 1,5-dichloro-9,10-dianilinoanthracene, m. 271° , 1,5-dichloro-9,10-dimethylanilinoanthracene (does not m. below 310°) and 1,5-dichloro-9,10-tetramethyldiaminodiphenylanthracene (does not m. below 300°) were obtained somewhat similarly. I heated with $\text{C}_6\text{H}_5\text{N}$ gave 1,5,9-trichloroanthronylpyridinium chloride, yellow but does not melt, gives a picrate, m. 253° , in H_2O .

E. J. WITZEMANN

Indan bases. CH. COURTOT AND A. DONDELINGER. *Ann. chim.* 4, 222-30(1925); cf. C. A. 19, 1859.—It has been previously shown that indanyl bromide reacts uniquely with primary aromatic amines to give only sec. amines in good yields and not a mixt. of sec. and tert. amines. C. and D. find that indanyl chloride reacts at *ordinary temp.* with aromatic amines to give sec. amines. The mobility of the α -position is not due necessarily to the nearness of the ethylenic bond, and the 5-membered ring may have a sp. action in increasing this mobility. Primary and sec. aliphatic amines have been found to react with indene- HCl . Mixed alkylarylamines also react with the indene- HCl to give the tert. amine in good yields. NHPh_2 gives only traces of diphenylindanyllamine, as decompn. occurs and polymerized indene is obtained. I. Synthesis of aliphatic indanyllamine derivs. *Ibid* 231-59.—Previous methods for prepg indanyllamine (I) are long. C. and D. prep. I from indene (II), a coal-tar product. To prep. II the coal-tar fraction b. $176-82^\circ$ is treated with NaNH_2 and distd. and the residue is extd. with water to liberate free II. A 98% yield of II. HCl (III) was obtained by improving Weissgerber's (C. A. 5, 3064) method. Aq. NH_3 reacts with III very slowly and after weeks gave 3 products, indanyllamine (IV), II and α -hydroxyhydrindene. Liquid NH_3 reacts with III slowly at low temp.; at room temp. under pressure it reacts in 12 hrs. I absorbs CO_2 very rapidly and under H_2 b_{747} 220.5° b_8 $96-7^\circ$. The mol. refraction of I is 41.55 (calcd. for a primary aliphatic amine, 41.38), showing no aromatic exaltation. It resembles closely tetrahydronaphthylamine and its continuous and selective absorption spectra in the ultra-violet, the degree of hydrolysis of its salts all confirm its aliphatic character. Diindanyllamine (V) is formed from liquid NH_3 and III under pressure; it m. $84-5^\circ$. Indanylmethylamine (VI), from liquid MeNH_2 and III for 12 hrs. (86% yield), b_{18} $106-7^\circ$. VI and MeI in ether give trimethylindanyllammonium iodide, m. 198° (VII). Indanyldimethylamine (VIII), prepd. from liquid Me_2NH and III, b_{10} $99-100^\circ$ (85% yield). VIII and MeI give VII. Liquid EtNH_2 and Et_2NH reacted with III to give indanylethylamine (IX) (65% yield), b_7 $106-7^\circ$, and indanyldiethylamine (X) (20-25% yield), b_{14} $108-26^\circ$. VI and III yield diindanylmethylamine (XI) (56% yield), m. $92-3^\circ$. VI and BzCl give indanylbenzylmethylamine (XII) (54% yield), b_{17} $197-8^\circ$. II. Synthesis of secondary and tertiary aliphatic amines. *Ibid* 260-92.—III and PhNH_2 give 53% of indanylphenylamine, m. $42-3^\circ$. III was treated directly with *o*-, *m*- and *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$ to give the corre-

sponding indanyltolylamines, m. 70.5–71.5°, b₉ 202–3°, m. 65.5–6.5°, resp. (yields 45.66 and 52%). With Me₂C₆H₃NH₂ **III** gives indanylxylylamine (55%), b₁₇ 218°. With PhNHMe and PhNH*i*Bt **III** gives the corresponding tert. amines, b₁₁ 191–2° (77%), and b₁₂ 193–4° (73%). **III** with Ph-NH gives an extremely low yield of a product seeming to be indanyldiphenylamine, m. 85–6°. **III** and aromatic primary amines condense almost instantaneously, aromatic alkylamines very rapidly and aliphatic amines more slowly. *o*-, *m*- and *p*-O₂NC₆H₄NH₂ with **III** give the corresponding sec. amines after several days. m. 87–8° and 92.5–3.5° (55%); 127–8° and 137–8° (50%) and 126–7° (30%). The *o*- and *m*-comps. have two m. ps. only when crystd. from EtOH. This may be due to EtOH of crystn. or formation of less stable isomers. The effect of the NO₂ group in the aromatic ring is a stabilizing one and also weakens the basicity of the amines. So as expected di- and trinitroaniline do not react with **III**. α-C₁₀H₇NH₂ and **III** give a noncrystallizable oil which is indanyl-α-naphthylamine but β-C₁₀H₇NH₂ and **III** give diindanyl-β-naphthylamine, m. 169–70°. α-Aminoanthraquinone and **III** give only **II** and no sec amine. Sulfonated amines did not react with **III**. **II** was hydrogenated quant. with Pt black to indan (**XIII**), b₁₀ 56–7°. EtMgBr reacts quant. with **II** at 100°, but does not react with **XIII** even at 135°. This shows the reactivity of the indene derivs. is due to the double bond in the 5-membered ring. In all of the comps. listed, not only have C. and D. made C, H and N detns., but also the d., mol. wts. in C₆H₆, *n* refraction and mol. refractions have been detd. **III**. **Preparation of the salts of the indan bases and determination of their electrolytic constants.** *Ibid* 293–326 —C. and D. prepd. the HCl salts of all the indan bases synthesized and some of the oxalates. Their prepn. offers a convenient method of purification. A study of the affinity const. and degree of hydrolysis of the HCl salts showed that in the indanylamine series the groups Me and *i*Bt linked to the N decrease the affinity const. (a. c.), while the Me group in the PhNH₂ series decreases and the *i*Bt group increases the a. c. The a. c. becomes lower in passing from BzNH₂ to **IV** than to PhNH₂. It is probable that this lowering is due to the aromatic, hydroaromatic and aryl aliphatic structure of the bases in question. The substitution of an indanyl group for an amino H atom lowers the a. c. and the ionization of the base. The substitution of the indanyl group in *o*-, *m*- and *p*-isomers does not change the relative positions of their a. c. Substituting the *p*-Me group in phenylindanylamine has only slight influence on the const. **IV**. **Optical study of the indan bases.** *Ibid* 327–45, cf. C. A. 19, 1859. **V. Action of the hydrogen acids on indene.** *Ibid* 345–69 —HCl reacts with **II** readily to form **III**, which decomp. slowly to give polymerized **II** and HCl vapor. **III** must be prepd. freshly and it is useless to attempt to purify it. HBr reacts with **II** even more rapidly than HCl does but the product is much less stable and cannot be purified. HI combines with **II** avidly but the product decomp. almost at once. The halogens are linked in the α-position in the indan ring. HF, like H₂SO₄, polymerized **II** into parindene.

D. H. POWERS

The influence of mercury on the sulfonation of anthraquinone. A. COPPENS. *Rec. trav. chim.* **44**, 907–30(1925). (In English.) —The behavior of Hg in the sulfonation of anthraquinone (**I**) has not been fully explained. In 1903–4 it was found that if **I** is sulfonated in the presence of Hg the reaction product consisted mainly of anthraquinone-α-sulfonic acid (**II**) instead of the β-SO₃H acid (**III**) which is the main product without Hg. It was suggested that the catalytic action of Hg could be ascribed to the formation of organometallic comps. Such an influence of a catalyst upon the position taken up by the constituent is rare (C. A. 1, 2580; Maarse, *Diss. Amsterdam* 1913, for another instance). The purpose of this work was to det. how the Hg acts and to demonstrate the occurrence of intermediate products. On the basis of the work of Roux and Martinet (C. A. 15, 1497) it may be supposed that the Hg will accelerate only the α-sulfonation without influencing the transformation α → β. This hypothesis complicates affairs needlessly and the formation of intermediate products has not been examd. It may also be supposed that the Hg accelerates the α-sulfonation catalytically without influencing the β-sulfonation which takes place simultaneously. The sulfonations were carried out according to Schmidt (*Ber.* 37, 66(1904)) thus: 100 g. **I** + 1 g. Hg₂SO₄ were ground together and kept at 150° with 120 g. 20% oleum while stirring. After cooling the reaction product was poured into 1400 cc. H₂O, boiled, filtered to remove pptd. **I**, boiled with "purit," filtered again and to the filtrate which was heated to 80–90° 70 cc. satd. KCl were added. At 60–70° the K salt which had sepd. was filtered off, washed with cold H₂O and recrystd. from H₂O. The mother liquor was found with H₂S to be free of Hg. The Hg could not be recovered by extg. the unchanged **I** with boiling H₂O. The Hg was found in the unchanged **I** in a non-ionizable form which could not be removed by boiling with dil. acids. The results showed that in the unchanged

I recovered from a sulfonation with Hg an org. Hg compd. is present analogous to that obtained from anthraquinonesulfonic acid and HgCl_2 . From this it is evident that such a compd. is formed in sulfonating with Hg. This compd. cannot be the product of a side reaction because the unchanged I when sulfonated again gives the same amt. of II as when ionic Hg is added. Moreover anthraquinone- α -mercuric chloride added as a catalyst gave about the same amt. of II. But from the fact that the greatest part of the Hg is found in the recovered I and none is in ionic form, it cannot be concluded that during the reaction Hg is largely bound to I so that the velocity of the mercuration is great compared with that of the sulfonation. In about 0.5 hr the sulfonation is nearly complete; in the 2nd 0.5 hr. practically no sulfonation takes place. The SO_3 concn. has fallen considerably and the Hg compd. can no longer be sulfonated rapidly. The result will be that all the Hg is transformed into an org. Hg compd., while practically none of this compd. disappears on sulfonation. This result is also reached when the velocity of mercuration is of the same order of magnitude as that of the sulfonation of the Hg compd. The course of the reaction is hypothetically formulated as follows: (1) $\text{C}_{14}\text{H}_8\text{O}_2 + \text{HgSO}_4 \longrightarrow (\text{C}_{14}\text{H}_7\text{O}_2)\text{HgSO}_4\text{H} (\alpha)$; $\text{C}_{14}\text{H}_7\text{O}_2\text{HgSO}_4\text{H} + \text{SO}_3 \longrightarrow (\text{C}_{14}\text{H}_7\text{O}_2)\text{SO}_3\text{H} + \text{HgSO}_4$ or $2\text{C}_{14}\text{H}_8\text{O}_2 + 2\text{HgSO}_4 \longrightarrow (\text{C}_{14}\text{H}_7\text{O}_2\text{Hg})_2\text{SO}_4 + \text{H}_2\text{SO}_4$; $(\text{C}_{14}\text{H}_7\text{O}_2\text{Hg})_2\text{SO}_4 + 2\text{SO}_3 + \text{H}_2\text{SO}_4 \longrightarrow 2(\text{C}_{14}\text{H}_7\text{O}_2)\text{SO}_3\text{H} + 2\text{HgSO}_4$. The 1st process is most probable because here collision of only 2 mols. is necessary, while in the last case collision of 4 mols. must take place simultaneously. In the 1st equation the velocity of reaction will be proportional to the HgSO_4 or Hg_2SO_4 concn. On doubling the quantity of Hg_2SO_4 the velocity of α -sulfonation should also be doubled. In the 2nd equation the velocity will be proportional to the 2nd power of the HgSO_4 concn. The results obtained with small concns. of Hg_2SO_4 where its slow soln. does not interfere show that the velocity is proportional to the Hg_2SO_4 concn. and accordingly the 1st equation is preferred. A method of estimating II and III in mixts. was worked out and is given in detail. This depended on a chlorination of II and III with $\text{KClO}_3 + \text{HCl}$ for 6 hrs. and detg. the final m. p. of the chloroanthraquinone formed. For this purpose, the m. p. diagram of the systems α - and β -chloroanthraquinone was detd. The Me esters of II and III were prepd. from the alkali salts and Me_2SO_4 ; that of III m. 163.4–4.2° and not as given by Heffter (*Ber.* 28, 2261 (1895)). An anthraquinone-Hg compd. which is probably anthraquinone- α -mercuric chloride was prepd. It was shown that such a compd. occurs in the mixt. of compds. obtained when I is sulfonated with Hg in the presence of insufficient oleum. In the presence of 2% Hg_2SO_4 at 156° 16.1% III is formed; in the absence of Hg 98–100% of III is formed. Sulfonation at 132° did not change the result. The temp. effect is about the same on both α - and β -sulfonations. I cannot be mercurated in the absence of H_2SO_4 . E. J. W.

9,10-Anthraquinone-2,3- and 1,2-quinonediazide and their derivatives. MUNE-NARI TANAKA. *Ber.* 58B, 1986–8 (1925).—3-Nitroanthraquinone-2-diazonium sulfate, obtained quant. from the 2-NH₂ compd. (m. 316°) diazotized in H_2SO_4 , yellow, deflagrates 133°, becomes red and finally brown-red in the light. When it is heated in concd. H_2SO_4 it evolves N at 120–30° and forms a brown-black mass but yields neither a quinonediazide nor 2,3- $\text{C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_3(\text{OH})\text{NO}_2$, but if it is heated in small amts. (0.5 g.) in Ac_2O about 0.5 min. at 95° it yields around 33% of 9,10-anthraquinone-2,3-quinonediazide, $\text{C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_2(:\text{O}): \text{N}_2$, metallic crystals with 0.75 Ac_2O which is completely lost at 150–70° (together with some N), sparkles in incident light, forms solns. which are almost always red (violet in $\text{C}_6\text{H}_5\text{N}$), is quite stable in the air, turns brown 160°, decomps. 227°, evolves gas with PhNHNH_2 at room temp., couples slowly with R salt with blue color, dissolves smoothly in concd. H_2SO_4 with blue color and is repptd. on diln., is sensitive to alkalis; in dil. alkali suspension with $\text{Na}_2\text{S}_2\text{O}_4$ at 66° it gives [2-hydroxyanthraquinonyl]-3-hydrazine, brown-red, decomps. 330–40°, which with much boiling Ac_2O yields a compd. (possibly the oximidazine $\text{C}_{16}\text{H}_{10}\text{O}_3\text{N}_2$; found, 9.65% N), m. 314°. 9,10-Anthraquinone-1,2-quinonediazide, from 1,2- $\text{C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_3(\text{NO}_2)\text{NH}_2$, red crystals with 0.75 Ac_2O . C. A. R.

Action of hydrazine hydrate on phenanthraquinone. A correction. SIKHIBHUSHAN DURR. *J. Chem. Soc.* 127, 2971 (1925); cf. C. A. 18, 684.—Phenanthraquinone and $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$ (50%) give 9,10-dihydroxyphenanthrene; anhyd. N_2H_4 gives phenanthrone. C. J. WESR

Condensation of β -ketonic acids with α,β -dichloroethyl ethyl ether. A. FUJITA. *J. Pharm. Soc. Japan* No. 519, 450–6 (1925).—Using Benary's method (C. A. 5, 1766), F. condensed $\text{CH}_2\text{ClCHClOEt}$ with $\text{CO}(\text{CH}_2\text{CO}_2\text{Et})_2$ in the presence of NH_3 and isolated 3-carboxy-2-furanacetic acid, but the expected 3-carboxy-2-pyrroleacetic acid could not be obtained. With $\text{BzCH}_2\text{CO}_2\text{Et}$ and $\text{CH}_2\text{ClCHClOEt}$ 2-phenyl-3-furan-carboxylic acid, and 2-phenylpyrrole were isolated, but the expected 2-phenyl-3-pyr-

rolecaboxylic acid could not be obtained, probably because of the ease with which decarboxylation can occur at the 3-position of pyrrole nucleus. S. T.

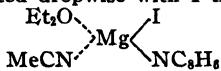

Pyrylium compounds. XVI. Triphenylpyrylium salts containing amino groups. W. DILLTHEY AND C. BERRER. *J. prakt. Chem.* 111, 340-52 (1925); cf. *C. A.* 20, 417.—While an NH_2 group in the *m*-position has little or no effect upon the color and behavior of triphenylpyrylium salts, the NH_2 group in the *p*-position acts as an auxochrome. *p*-AcNHC₆H₄CH:CHBz and BzMe in a little Ac₂O, treated with 3 mols ZnCl₂, give 15% of 4-[4-acetylaminophenyl]-2,6-diphenylpyrylium chloride-zinc chloride, straw-yellow, m. 158°; a soln. of EtOH-C₆H₅N, dild. with hot H₂O to turbidity, gives the pale yellow 4-[4-acetylaminophenyl]-2,6-diphenylpyranol, m. 188-9° (dark red melt); *perchlorate*, orange-yellow, m. 220-5° (decompn.). Concd. H₂SO₄ splits off the Ac group, giving with picric acid 4-[4-aminophenyl]-2,6-diphenylpyrylium *picrate*, violet-black needles with Cu luster, slowly decmps. above 250°; an *acid picrate* also results, brick-red and transformed by crystn. to the neutral *picrate*; *perchlorate*, steel-blue needles, slowly decmps. above 295°. *N*-acetylaminomethoxychalcone, light yellow, m. 186-7°; its solns. show light green fluorescence. With 4-MeOC₆H₄Ac and ZnCl₂, followed by HClO₄, there results 4-[4-acetylaminophenyl]-2,6-di-[4-methoxyphenyl]pyrylium *perchlorate*, orange-red, decmps. above 250°, m. 294° if rapidly heated; *picrate*, brick-red, m. 267° (decompn.). With 40% HBr, this gives the free *amino deriv.*, as the *bromide*, violet needles with green surface luster, m. 196°; *acid HCl salt*, dark brownish red, m. 205° (decompn.). Heating with concd. HCl 8 hrs. at 160° gives 4-(4-aminophenyl)-2,6-di-[4-hydroxyphenyl]pyrylium *acid chloride*, violet-red with a metallic luster, decmps. 240°; *perchlorate*, reddish yellow needles. 4-[4-Acetylaminophenyl]-2-[4-methoxyphenyl]-6-phenylpyrylium *perchlorate*, reddish orange, m. 143°. Deacetylation gave the free *amino deriv.*, analyzed as the *chloride-HCl*, violet-red with green metallic luster, which gives off HCl on heating. Concd. HCl gives 4-[4-aminophenyl]-2-[4-hydroxyphenyl]-6-phenylpyrylium *chloride*, violet needles with green luster, decmps. 230°; *HCl salt*, violet-red, decmps. 240°. 2,4-Di-[4-aminophenyl]-6-phenylpyrylium *picrate*, violet-black needles, giving a deep red aq. EtOH soln. with marked dyeing capacities. C. J. WEST

Dimethylisoidigotin and a new decomposition of the disulfisatides. A. WAHL AND T. FAIVRET. *Compt. rend.* 181, 790-2 (1925).—W. and F. on reducing 5-methyl-(I) and 7-methylisatin (II) obtained 5- and 7-methyldioxindole but could not obtain pure 5-methyl- (III) or 7-methyloxindole (IV). A catalytic reduction of isatin and of I gave diisatide and 5,5-dimethylisatide, but II gave no corresponding product. I and II in boiling EtOH with H₂S gave non-cryst. 5,5- (V) and 7,7-dimethyldisulfisatide (VI). Treating V and VI with pyridine at 100° gave 5,5-dimethylisoidigotin (its leuco base m. about 330°) and 7,7-dimethylisoidigotin, having a non-crystalline leuco base. From the C₆H₅N mother liquor was obtained 5-methyloxindole, m. 168°, and 7-methyloxindole, m. 203-40°. Their benzylidine derivs. m. 182° and 224°, resp.

Synthetic experiments in the indole group. V. Synthesis of β -indolyethanolamine. RIKO MAJIMA AND MUNIO KOTAKE. *Ber.* 58B, 2037-41 (1925); cf. *C. A.* 19, 279.—Cold β -indolaldehyde (I) and excess of PhNH₂ with concd. HCl give β -indol-aniline-HCl, yellow needles from EtOH-Et₂O, decmps. 240-6°, seps. from hot HCl, on cooling, in red needles, decomp. about 200°, which apparently contain 1 H₂O; free *aniline* (II), m. 126-7°. *N*-Acetyl- β -indolaldehyde (III), from II, Ac₂O and NaOAc at 95-105°, or, in 11 g. yield, from 10 g. I, Ac₂O and NaOAc at 102°, m. 159-62°; the AcOEt mother liquors yield its *diacetate*, AcC₆H₄NCH(OAc)₂, m. 154°. *N*-Acetyl- β -indolaldehyde-aniline-HCl, AcC₆H₄NCH(OH)NHPH₂·HCl, from III, PhNH₂, hot H₂O and concd. HCl, yellow, m. 191-4°. *N*-Acetyl- β -indolyl- ω -nitroethanol (8.3 g. from 10 g. III and 20 g. MeNO₂ in 64 cc. 10% KHCO₃ shaken 200-50 hrs. at 30°; this temp. and concn. of KHCO₃ must be adhered to closely), m. 138.5-40.5°, easily sol. in alkalis with brownish red color, AcOH pptg. III from the soln.; with Ac₂O and NaOAc at 165° it gives *N*-acetyl- β -[ω -nitrovinyl]indole, yellow, m. 189-92°, while 2.5 g. with SnCl₄ and HCl gas in cold AcOH gives 1.2 g. *N*-acetyl- β -indolyethanolamine-HCl (IV), apparently hydrated leaflets, m. partially 53-7°, completely 163-6°; *chloroplatinate*, brownish, blackens somewhat around 200°, decmps. about 225°; *picrate*, yellow, m. 174-6° (decompn.). IV in H₂O with alkali gives an oil yielding with picric acid orange crystals, decomp. 188°, having the compn. of β -indolyethanolamine *picrate*. [*N*-Acetyl- β -indolyl]-*N*,*O*-diacetyl ethanolamine (0.3 g. from 0.5 g. IV with Ac₂O-NaOAc in the H₂O bath), m. 68-71°, gives with alc. KOH at room temp. β -indolyl-*N*,*O*-diacetyl ethanolamine, decmps. 202-4°. VI. A new synthesis of β -indolyalkylamines. RIKO MAJIMA AND TOSHIO HOSHINO. *Ibid* 2042-6.—Indolylmagnesium iodide (I) in

cold PhOMe treated dropwise with 1 mol. MeCN in PhOMe gives a greenish gray sirup, presumably

, which is unchanged by heating 30 min. at 60–70° and on decompn. with ice in the usual way gives back the unchanged indole quant. The I from 7.8 g. indole similarly treated with ClCH₂CN likewise gives a gray sirup which, heated 20 min. at 60–70° and decompd. with ice, yields 5.3 g. β -indolylacetonitrile (V), faintly yellow-brown, b_{0.2} 160°; *picrate*, orange, m. 127–8°. V is also obtained in 47% yield in Et₂O instead of PhOMe. Boiled 6 hrs. with 20% KOH it gives 84% β -indolylacetic acid, decomp. 164.5–5.0°; *picrate*, decomp. 178°. β -[β' -Indolyl]-propionitrile (VI) (16.8 g. from the I from 18 g. indole with ClCH₂CH₂CN), m. 67–8°, b₁ about 200° (*picrate*, red, m. 123.5–4.5°); *acid*, m. 133–4° (*picrate*, m. 141–3°). β -[β' -Indolyl]ethylamine (4 g., together with 1.2 g. skatole, from 6 g. V in boiling abs. alc. treated in the course of 15 min. with 7.1 g. Na), m. 114.5–5.5°; *HCl salt*, decomp. 248–9°; *picrate*, decomp. 242–3°; *acetate*, loses 0.5 mol. H₂O at 56° and m. 135–6°. β -Indolylacetamide (2.5 g. from 8.5 g. V in boiling 85% AcOH with Zn dust), m. 150–1°. γ -[β' -Indolyl]propylamine (4.1 g. from 5 g. VI with Na in boiling alc.), hygroscopic, m. 60–4°; *HCl salt*, m. 169–70°; *picrate*, red needles with 3H₂O, sinters 82°, becomes yellow, begins to foam 103°, m. completely 146–9°; the yellow anhyd. crystals m. 155–6°.

C. A. R.

Velocity of decomposition of heterocyclic diazonium salts. I. Diazonium salts of the pyrazole and pyrazolone series. JOSEPH REILLY AND DENIS MADDEN. *J. Chem. Soc.* 127, 2936–40 (1925).—A definite vol. of a soln. contg. a known wt. of the amine (sufficient to give 56 cc. of gas under standard conditions, normal diazotization being assumed) was heated in a quartz vessel at 100° (bath temp., 101.5°), a current of air-free CO₂ being passed periodically through the soln. The following values for $k(t)$ measured in min., % decompn. in first hr. and time (min.) for half decompn. were obtained: *m*-O₂NC₆H₄NH₂, 0.0322, 100, 10; *o*-O₂NC₆H₄NH₂, 0.00564, 54, 53; 4-amino-pyrazole, 0.00317, 40, 80; 4-aminoantipyrine, 0.00088, 13, 360; 4-amino-3,5-dimethyl-pyrazole, 0.00030, 1.7–2, 1020. In the case of antipyrine-4-diazonium salts, the rate of decompn. is considerably influenced by the nature of the anion; the chloride and nitrate follow mainly a unimol. law, while the sulfate does not, the rate of decompn. being much more rapid at the beginning.

C. J. WEST

Some derivatives of phenylpropionaldehyde and of α -bromocinnamaldehyde. K. v. AUWERS AND B. OTTENS. *Ber.* 58B, 2060–71 (1925).—The object of this work was to det. under what conditions the semicarbazones, phenylhydrazones and oximes of PhC: CCHO (I) and PhCH: CBrCHO (II) can be converted into heterocyclic compds. I and H₂NCONHNH₂.AcOH in the cold regularly give 2 compds. sepd. by their differing soly. in C₆H₆: III, the less sol., m. 193–4°, and IV, m. 132–4°; the crude products generally contain 25% III and 60% IV. III is changed into IV by acids. Both are semicarbazones and can be hydrolyzed to I, and yield BzOH with KMnO₄. They are therefore the stereoisomeric *cis-trans*-semicarbazones; which configuration corresponds to each could not be detd. The compd. obtained by the addn. of alc. to PhC: CCH(OEt)₂ (Lieske, *Diss. Kiel*, 1908, 20) is α -ethoxycinnamaldehyde di-Et acetal (V), as shown by its spectrochem. const. and by the fact that its semicarbazone (VI), m. 151–2°, cannot be converted into a ring compd. The semicarbazone (VIII) of II is likewise unchanged by heating several hrs. with AcOH; hot alc. KOH converts it into III. Similarly, neither of the phenylhydrazones of I can be converted into 1,5-diphenylpyrazole and the phenylhydrazone of II is unchanged or resinified by hot HOAc and with alc. KOH yields the labile phenylhydrazone of I. The phenylhydrazones of PhCH: C(OEt)CHO and PhCH: CMeCHO behave in the same way. On the other hand, the methylhydrazone of I gives with great ease 1-methyl-5-phenylpyrazole (VIII), which is obtained directly even in the cold. By working at a lower temp. (–15°), the solid unstable intermediate product in the prepn. of VIII from II and MeNHNH₂ (C. A. 19, 2048) has now been obtained in greater amt. and shown to be PhCH: CBrCH(OH)NHNHMe (IX); mineral acids decomp. it in the cold into II and MeNHNH₂. On decompn., it loses H₂O and from the product can be isolated, by rubbing with Me₂CO, a small amt. of what is apparently 4-bromo-1-methyl-5-phenylpyrazoline-HBr (X), m. 129–30°. If the original material is allowed to stand under Et₂O it decomp. gradually with formation chiefly of VIII, together with some II and MeNHNH₂. The oxime of I resembles the methylhydrazone in the ease with which it forms a ring compd. Even under the mildest possible conditions it gives PhC: CCN with Ac₂O, as found by Claisen (*Ber.* 36, 3671 (1903)), and not an Ac deriv. The oxime of II on the other hand yields an Ac deriv. under mild conditions and gives the nitrile only at high temps.;

from cold NaOH acids ppt. it unchanged but on gentle warming the odor of PhC:CH develops and acids now ppt. the oxime of I. Possibly the 2 oximes are to be represented by the formulas PhC:CCH and PhCH:CBBrCH. I b_{10} 105-8°, $d_4^{15.8}$ 1.0639, d_4^{20}

Formation and rearrangement of pyrazolecarboxamides. K. v. AUWERS and B. OTTENS. *Ber.* 58B, 2072-80(1925).—This work was undertaken to det. whether 3(5)-phenylpyrazole (I), like the Me compd. (*C. A.* 19, 2953), can form 2 structurally isomeric carboxamides. PhCOCH:CHOH (II) cautiously treated with H₂NCONHNH₂ in neutral or faintly alk. or acid (AcOH) soln. yields a *semicarbazone* (III), m. 175-6°, sol. in alkalis with yellow color, also obtained regularly from H₂NCONHNH₂ and the benzoate or Et ether of II, even at -15°. III easily yields a *disemicarbazone* (IV), m. 238°, which is also obtained in greater or lesser amt directly from II or its *O*-derivs. with H₂NCONHNH₂. CO₂ or mineral acids at a low temp ppt. III unchanged from alkalis but at room temp. acids give a *carboxamide* (V), m. 142-3°. An isomeric *carboxamide* (VI), m. 133°, is formed when II in alc. is treated with H₂NCONHNH₂·HCl; it is less easily sol. in Et₂O than its isomer and is hydrolyzed to I in MeOH or EtOH by picric acid at moderately high temps, while V gives a light yellow *picrate* (VII), m. 165-6°. Both V and VI give the same Ag salt, m. 85°, of I with AgNO₃. II at -15° with H₂NCONHNH₂·HCl gives III, which on cautious treatment with alc. and concd. HCl is converted into VI. V and VI are, therefore, both derived from III. VI can be converted into V under various conditions of heating. Thus VI, melted at 133°, resolidifies and m. again 142°; heating with AcOH or boiling 15 min. in C₆H₆ effects the same change; the product is now easily sol. in Et₂O and yields VII. Whether the isomerism persists in reactions which involve the nucleus could not be detd.; V readily yields a faintly yellow *mono-Br deriv.*, m. 161-3°, while with VI, even at -15°, the CONH₂ group is split off with formation of 4-bromo-3(5)-phenylpyrazole-*HBr*, m. 186-7° (free base, m. 116-7°). The oxime (VIII), m. 189-90°, of III is entirely different from benzoylacetalddehyde 1-oxime-3-semicarbazone (IX), PhC:(NNHCONH₂)CH₂CH:NOH, m. 154° (decompn.). With hot HCl IX gives a mixt. of I and V, while VIII yields γ -phenylisoxazole (X), showing beyond doubt that VIII has the structure PhC:(NOH):CH₂CH:NNHCONH₂, and, consequently, III the structure PhCOCH₂CH:NNHCONH₂; the soly. in alkalis of III is to be explained by the enolizing influence of the unsatd. grouping—CH:N—on the system—CO.CH₂—. These facts also establish that V and VI have the structures N:CPh.CH:CH.NCONH₂ and PhC:CH.CH:N.NCONH₂,

resp., and are completely analogous to the Me compds. When the H on the N of I is replaced by COCl by means of COCl₂ and the Cl is then replaced by NH₂, V is formed even at low temps.; it is also formed by the addn. of HOCN to I. The X obtained from VIII was identical with a sample prepd. by Zöpfchen's method (*Diss. Kiel, 1899*); it m. 1-2°, b_{30} 145°, $d_4^{18.7}$ 1.1406, d_4^{20} 1.139, n 1.56288, 1.56916, 1.58455, 1.59864 for α , He, β and γ at 18.7°, n_{He}^{20} 1.5686, $E\Sigma$ (av. for 2 samples) -0.18, -0.15, 17%, 20% for α , D, β - α and γ - α . For comparison was prepd. α -phenylisoxazole, b_{11} 128°, m. 22°.

d_4^{18} 1.1399, d_4^{20} 1.139, n_D^{18} 1.57921, 1.58693, 1.60670, 1.62541 at 18.8°, n_{He}^{20} 1.5864, E_D (av. for 2 samples) 0.49, 0.57, 47%, 54%. Only the α -deriv. forms a difficultly sol. $HgCl_2$ compd. and the γ -compd. dissolves in very concd. HCl , is hardly attacked by even hot aq. alkalis but is gradually converted by alc. alkalis into $PhCN$ and $AcOH$. *Benzoylacetalddehyde dioxime*, m. 109–10°; heated 10 min. on the H_2O bath with concd. HCl it yields a mixt. of about equal parts of the isomeric phenylisoxazoles, for the product with $NaOEt$ at room temp. gives **X** and $PhCOCH_2CN$. C. A. R.

Influence of constitution on the transformation of phenylhydrazones of unsaturated compounds into pyrazolines. II. K. v. AUWERS AND A. KREUDER. *Ber.* 58B, 1974–86 (1925); cf. *C. A.* 4, 586. As a rule, unsatd. aliphatic aldehydes yield phenylhydrazones while the corresponding derivs. of unsatd. ketones are so unstable that in attempts to prep. them they rearrange into the isomeric pyrazolines. The aldehyde phenylhydrazones in general do not readily change into the pyrazolines; they usually distil unchanged *in vacuo* and on heating with $AcOH$ chiefly undergo hydrolysis, with partial resinification. A p - NO_2 group in the $PhNH$ = residue hinders the change into the pyrazoline, while o - and p - Me and o - Cl substituents exert no marked influence. Aliphatic hydrazones ($RCH.NNHMe$) are far less stable than phenylhydrazones. That the Knorr reaction does not permit of distinguishing with certainty between phenylhydrazones and pyrazolines has been further confirmed by the present work, although there are certain differences between the color reactions of pyrazolines, hydrazones and phenylhydrazides; the hydrazones, unlike the pyrazolines, give no color when treated in dil. alc. soln. dropwise with $FeCl_3$ and H_2SO_4 (but under these conditions the reaction is also sometimes negative with pyrazolines). It is always advisable, therefore, to reduce the substance in question; the yield of $PhNH_2$ from the phenylhydrazones is 10–40%. In the case of the substituted hydrazones (e. g., the bromophenylhydrazones) it is not always so easy to det. the constitution, but the p -nitrophenylhydrazones can readily be distinguished from the pyrazolines by the intense red or violet color with which they dissolve in alc. alkalis. $CH_2:CHCHO$ with $PhNHNH_2$ in cold Et_2O yields a mixt. of 1-phenylpyrazoline, m. 51–2°, and $CH_2:CHCH:NNHPh$, for with $Na-Hg$ it gives considerable $PhNH_2$ and with 33% H_2SO_4 at room temp. it yields $PhNHNH_2$. $MeCH:CHCHO$ and $PhNHNH_2$ without a solvent yield the phenylhydrazone, m. 56–7°, b_D^{16} 165° (slight decompn.), quickly darkens and decomp. in the air but is stable for a considerable time under H_2O . *Tiglic aldehyde phenylhydrazone*, m. 92–4°, b_D^{16} 155–60°, b_D^{17} 163–8°, becomes yellowish in the air, is slowly hydrolyzed by cold 20% H_2SO_4 , more rapidly on the H_2O bath, gives the Bulow reaction either very faintly or not at all. α -Methyl- β -ethylacrolein phenylhydrazone, m. 60°, b_D^{16} 171–5°, is hydrolyzed by 20% H_2SO_4 and by boiling $AcOH$, gives $PhNH_2$ with $Na-Hg$, becomes red-brown and partly liquefies in the air; from a sample which had stood 5 months in an open bowl was isolated $HCONHNHPh$. $MeCH:CHCOMe$, d_4^{18} 0.8568, d_4^{20} 0.856, n_D^{18} 1.43710, 1.44078, 1.45016, 1.45833 for α , He , β and γ at 18.6°, E_D 1.23, 1.31, 32%, 37% for α , D , β - α and γ - α , gives in cold $EtOH$ - $AcOH$ 1-phenyl-3,5-dimethylpyrazoline, b_D^{18} 173–5°. Mesityl oxide with $PhNHNH_2$ in $EtOH$ - $AcOH$ yields 60% 1-phenyl-3,5,5-trimethylpyrazoline, b_D^{18} 152–3°, while in alc. with aq. p - $O_2NC_6H_4NHNH_2$ it gives the p -nitrophenylhydrazone, orange-yellow, m. 132–4°, gives a purple color in Me_2CO with alkalis, is smoothly rearranged by boiling $AcOH$ into 1-[p -nitrophenyl]-3,5,5-trimethylpyrazoline (obtained directly from mesityl oxide refluxed in aq. $MeOH$ with $O_2NC_6H_4NHNH_2 \cdot HCl$), deep yellow, m. 205–8°, which is unchanged by boiling $AcOH$ or by alc. HCl or H_2SO_4 at 160–240°, but when refluxed 50–60 hrs. with a mixt. of 3 parts $AcOH$ and 1 part 60% H_2SO_4 or 15 parts $AcOH$ and 1 part concd. H_2SO_4 it oxidizes and rearranges into 1-[p -nitrophenyl]-3,4,5-trimethylpyrazole, pale greenish yellow, m. 116–6.5° (also obtained in 66% yield from the pyrazoline in boiling $AcOH$ with Br , and in 80% yield from $MeCHAc_2$ and p - $O_2NC_6H_4NHNH_2 \cdot HCl$ in H_2O). 1-[p -Nitrophenyl]-3,5-dimethylpyrazole (86% from CH_2Ac_2 and $O_2NC_6H_4NHNH_2 \cdot HCl$), yellow, m. 99.5–100.5°. Phorone and $PhNHNH_2$ in boiling $EtOH$ - $AcOH$ or in alc. at room temp. give 1-phenyl-3-isobutenyl-5,5-dimethylpyrazoline, yellowish, b_D^{17} 186–9°, becomes dark brown-red on standing, resinifies in the air. From 25 g. $PhCH:CHCOMe$ with $MeNHNH_2$, H_2SO_4 and $NaOAc$ in boiling aq. alc. is obtained 19 g. 1,3-dimethyl-5-phenylpyrazoline, b_D^{18} 123–4°, b_D^{24} 243–5° (some decompn.) (picrate, m. 128–30°), while o - $MeC_6H_4NHNH_2$, $AcOH$ in tepid aq. alc. yields the o -tolylhydrazone, yellow, m. 176–8°, giving in concd. H_2SO_4 with $FeCl_3$ a very transient red color and converted by boiling $AcOH$ into 1- o -tolyl-3-methyl-5-phenylpyrazoline, yellow, m. 82–3°, which gives a somewhat more stable red color in H_2SO_4 with $FeCl_3$. p -Tolylhydrazone, best obtained in $EtOH$ - $AcOH$ at room temp., yellow, m. 120–1°, gives a transient green color with $FeCl_3$ in H_2SO_4 .

cannot be reduced by Na-Hg and AcOH under the usual conditions, converted by boiling AcOH and partly by distn. *in vacuo* into the *pyrazoline*, viscous yellow oil, b_{28} 215-9°, gives with FeCl_3 in H_2SO_4 a violet color and forms a *picrate* m 111-2° which gives the Knorr reaction just as intensely as the free base. *p*-Nitrophenylhydrazones, cinnabar-red, m. 165-7°, is obtained almost instantly from PhCH:CHCOMe and $\text{O}_2\text{NC}_6\text{H}_4\text{NHNH}_2 \cdot \text{HCl}$ in suitable solvents; if PhCH:CHCOMe and $\text{O}_2\text{NC}_6\text{H}_4\text{NHNH}_2$ are boiled in aq. alc., the red ppt. gradually dissolves and after heating 1 hr. there seps. on cooling a mixt. of red and egg-yellow crystals which persist after 3 hrs.' heating but after 8 hrs. only the yellow form seps.; boiling C_6H_6 and PhMe do not change the hydrazone but in AcOH on the H_2O bath it rapidly isomerizes into the *pyrazoline*, m. 149°. *o*-Chlorobenzalacetone, b_{17} 154-5°, with PhNHNH_2 in EtOH-AcOH at room temp. gives the yellow *phenylhydrazone*, m. 92-3°, slowly sol. in concd. H_2SO_4 with brown color gives a transient green color with FeCl_3 , converted by boiling AcOH into the *pyrazoline*, light ochre, m. 87°, gives an intense violet, then Burgundy-red Knorr reaction, in alc. from red-violet through blue to green. *o*-Tolylhydrazone, light yellow, m. 92-3°, darkens and gradually resinifies in the air, gives a transient red color with FeCl_3 in H_2SO_4 ; *pyrazoline*, yellow, m. 96-8°, shows green fluorescence in C_6H_6 , benzine and CHCl_3 and in the molten state; a crude sample of the hydrazone which would not cryst. yielded on distn. a dark oil b_{21-2} 220-30° which after a week deposited colorless crystals, presumably of 1-*o*-tolyl-3-methyl-5-[*o*-chlorophenyl]pyrazole, m. 98-9°, giving no color with FeCl_3 in H_2SO_4 and unchanged by boiling AcOH. *p*-Tolylhydrazone, light yellow, m. 122-3°, gives with FeCl_3 in H_2SO_4 a transient dark green color; *pyrazoline*, m. 77.5-8.5°, b_{17} 205-20°, gives a deep blue-violet color with FeCl_3 in H_2SO_4 , and on oxidation in alc. a green color. *p*-Hydroxybenzalacetone phenylhydrazone, dark red, almost black, m. 218-20° (decompn.), changes in dil. alc. or Me_2CO solns on addn. of alkali from orange to bluish red; *pyrazoline*, cinnabar-red, m. 149-51° (decompn.). $\text{Me}_3\text{CCOCH:CHPh}$ and *o*- $\text{MeC}_6\text{H}_4\text{NHNH}_2$ in EtOH-AcOH at room temp. give 1-*o*-tolyl-3-*tert*-butyl-5-phenylpyrazoline, m. 94-5°, gives a red-violet color with FeCl_3 in H_2SO_4 ; *p*-tolyl isomer, m. 116-7°, gives a blue-violet Knorr reaction. PhCH:CHCOMe and *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{NHNH}_2 \cdot \text{HCl}$ under various conditions always yielded mixts. of the hydrazone and pyrazoline but the 3,5-diphenyl-1-[*p*-nitrophenyl]pyrazoline, yellow, m. 177-7.5°, was obtained pure when the 2 reagents in alc. were boiled some hrs. with a little concd. HCl. C. A. R.

Constitution of the stable and labile acylindazoles. K. V. AUWERS. *Ber.* 58B, 2081-8 (1925); cf. C. A. 19, 509, 3091.—v. A. has at last succeeded in obtaining what he considers to be positive proof that the stable and labile "2-acylindazoles" are in reality structural isomers, *i. e.*, 1- and 2-acyl derivs. *o*-($\text{o-MeC}_6\text{H}_4\text{SO}_2\text{NH}$) $\text{C}_6\text{H}_4\text{CH:NOH}$ (I) treated with Beckmann's mixt. is not dehydrated but merely acetylated, with formation of a *product* (II), m. 151-3°, whose m. p. falls, however, on recrystn. of any kind, and finally becomes const. at 129-31°. Inversely, the lower melting form (III) changes back into II when treated with HCl gas in cold AcOH-Ac₂O. The nature of the isomerism between II and III has not yet been established; as both are easily hydrolyzed back to I by alkalis, they must both have the structure $\text{MeC}_6\text{H}_4\text{SO}_2\text{NHC}_6\text{H}_4\text{CH:NOAc}$. At higher temps. (180-90°) II and III lose AcOH with formation of $\text{MeC}_6\text{H}_4\text{SO}_2\text{NHC}_6\text{H}_4\text{CN}$ (IV). The desired indazole formation can be effected by treating II or III with alkalis under suitable conditions. At higher temps. is obtained exclusively or almost so the normal sapon. product (I), but the lower the temp. is kept the greater is the amt. obtained of 1-[*o*-toluenesulfonyl]indazole (V), m. 108°, which on hydrolysis yields indazole; this is almost the sole product when the II or III is rubbed with NaOH in the cold or treated in Me_2CO with Na_2CO_3 . V is also obtained from indazole with *o*- $\text{MeC}_6\text{H}_4\text{SO}_2\text{Cl}$ on the H_2O bath, while in cold $\text{C}_6\text{H}_5\text{N}$ is obtained the 2-isomer (VI), m. 81-4° (yield, 65-70%), which is stable for a short time above its m. p. but rearranges into V when boiled a long time in high boiling ligroin. It has not been possible thus far to convert the free I into an indazole. *o*-($\text{p-MeC}_6\text{H}_4\text{SO}_2\text{NH}$) $\text{C}_6\text{H}_4\text{CH:NOH}$ (VII) is not acetylated by Beckmann's mixt. but converted into a lower melting isomer, m. 123-5°. The *acetate* (VIII) of VII (obtained with boiling Ac₂O), however, gives with alkalis either VII or an indazole (IX) or a mixt. of the 2, depending on the conditions. As there is no reason for considering the possibility of a shifting of the $\text{MeC}_6\text{H}_4\text{SO}_2$ residue in these expts. it follows that the compds. hitherto considered as the stable 2-acylindazoles are really 1-derivs. and their formation from the labile isomers depends on a migration of the acid radical. *N*-[*o*-Toluenesulfonyl]-*o*-aminobenzaldoxime (I), obtained in 35-40% yield from $\text{H}_2\text{NC}_6\text{H}_4\text{CH:NOH}$ and 1 mol. $\text{MeC}_6\text{H}_4\text{SO}_2\text{Cl}$ in cold $\text{C}_6\text{H}_5\text{N}$, m. 130-1°, changes into IV when boiled 5 min. *in vacuo*. III is obtained directly when I is boiled a short time with Ac₂O and pptd. with C_6H_6 or when I is allowed to stand in Ac₂O-AcOH without passing in HCl. *N*-[*o*-Toluenesulfonyl]-*o*-aminobenzonitrile (IV), m.

125–6°, easily sol. in dil. alkalis and NH_4OH , is identical with the product obtained from $\text{H}_2\text{NC}_6\text{H}_4\text{CN}$ and $\text{MeC}_6\text{H}_4\text{SO}_2\text{Cl}$ in $\text{C}_6\text{H}_5\text{N}$. VI is at once hydrolyzed in Et_2O by HCl and on standing in the air changes in great part into indazole *o*-toluenesulfonate, m. 167–9°. *N*-[*p*-Toluenesulfonyl]-*o*-aminobenzaldoxime (VIII), m. 136–6.5° (15 g. from 10 g. $\text{H}_2\text{NC}_6\text{H}_4\text{CH:OH}$). VIII, m. 101–2.5°. 1-[*p*-Toluenesulfonyl]indazole (IX), m. 103–4°. C. A. R.

Quantitative determination of nitramino and nitrimino groups. KURT LEHMSTEDT AND OTTO ZUMSTEIN. *Ber.* 58B, 2024–7(1925).—On the assumption that in the application of the Schulze-Tiemann method (reduction with $\text{FeCl}_2\text{-HCl}$) to compds. contg. both $\text{C}(\text{NO}_2)$ and $\text{N}(\text{NO}_2)$ groups the former probably would not be attacked, the method was tested on 1,1',5,5'-tetrinitro-2,2'-diimidazolyl (I); 2 mols. NO were smoothly split off but the resulting di- NO_2 compd. is so unstable that it could not be isolated. 2- $\text{C}_6\text{H}_4\text{NNHNO}_2$ (II), on the other hand, smoothly yielded 1 mol. NO and 87% 2- $\text{C}_6\text{H}_4\text{NNH}_2$ 1,5,5'-Trinitro-2,2'-diimidazolyl (III) and 5,2- $\text{C}_6\text{H}_3\text{N}(\text{NO}_2)\text{NHNO}_2$ (IV) (decomps. 158–9°) likewise gave 1 mol. NO each. The Lunge method (shaking in concd. H_2SO_4 with Hg) is not applicable to nitramines which are easily rearranged by acids into nucleus-nitrated amines; thus, II gave only 3.93–5.01% nitramine N instead of the calcd. 10.07%, while I and IV gave the theoretical amts.; in the last case was isolated 87% 5,2- $\text{C}_6\text{H}_3\text{N}(\text{NO}_2)\text{NH}_2$, m. 188°. C. A. R.

Benzo-(*i*)-1,2-thiazole. R. STOLLÉ (WITH W. GEISEL AND W. BADSTÜBERN). *Ber.* 58B, 2095–100(1925).—Thionaphthenequinone (4.9 g.) treated dropwise in cold concd. NH_4OH with perhydrol gives 3.5 g. benzo-(*i*)-1,2-thiazole-3-carboxamide, $\text{C}_6\text{H}_4\text{S.N:CCONH}_2$ (I), m. 134°, sol. in concd. H_2SO_4 with yellow color, and (*o*- HO_2C -

$\text{C}_6\text{H}_4\text{S}$)₂, m. 289°. 3- CO_2H acid (II) (6 g. from 7.1 g. I with boiling *N* NaOH), m. 143°, sol. in Na_2CO_3 and alkalis, in H_2SO_4 with yellow color, gives in alc. with AgNO_3 a gelatinous ppt. sol. in NH_4OH ; heated at 175° until the evolution of CO_2 ceases it gives benzo-(*i*)-1,2-thiazole, m. 37°, b. 220°, sol. in concd. acids (with yellow color in H_2SO_4), has an odor like that of oil of bitter almonds and is volatile with steam; *AgNO}_3* compd. ($\text{C}_7\text{H}_4\text{NS}$)₂. AgNO_3 , m. 105°, easily changes in the light. *Et ester* of II (2.8 g. from 3.5 g. I refluxed in alc. satd. with HCl), m. 44°, sol. in H_2SO_4 with yellow color; *AgNO}_3* compd. (1:1), m. 170°, easily changes in the light. *Hydrazide* of II (6 g. from 7.1 g. I refluxed in alc. with $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$), m. 138°, sol. in dil. acids, in concd. H_2SO_4 with yellow color, gradually reduces hot $\text{NH}_3\text{-AgNO}_3$, quickly on addn. of NaOH; *benzylidene deriv.*, m. 231°. *Azide* (5 g. from 5.8 g. of the hydrazide in cold dil. HCl with NaNO_2), m. 102° (decompn.), deflagrates weakly when rapidly heated on Pt, gives with PhNH_2 the *carboxanilide*, m. 126°. *Et [benzo-(*i*)-1,2-thiazol]aminoformate*, from the azide boiled in alc., m. 107°; with concd. HCl in a sealed tube at 105–10° it gives 3-aminobenzo-(*i*)-1,2-thiazole, m. 115°, pptd. from dil. HCl by concd. acid as the HCl salt, gives in hot H_2O with Pergelon soln. an orange-yellow ppt. (probably the azo compd.) and in HCl with NaNO_2 a substance m. 151°, insol. in Na_2CO_3 and NH_4OH but sol. in NaOH. [α -Naphtho-(*i*)-1,2-thiazole]-3-carboxamide, from α -benzothionaphthenequinone and H_2O_2 , yellow m. 245°, sol. in H_2SO_4 with red-yellow color, also obtained from the quinone in NH_4OH with air. The corresponding *Et ester* (6.5 g. from 7 g. of the amide), m. 131°, sol. in H_2SO_4 with canary-yellow color, forms in alc. a *AgNO}_3* compd., decomps. 215°. Free acid, from the ester refluxed in 20% HCl , m. 212° (decompn.), sol. in H_2SO_4 with canary-yellow color, forms in alc. with AgNO_3 a gelatinous ppt. sol. in NH_4OH . C. A. R.

2-Phenyl-5-aminotetrazole. R. STOLLÉ AND O. ORTH. *Ber.* 58B, 2100–5(1925).—2-Phenyl-5-aminotetrazole (I) has only very weak basic properties and, unlike the 1,5-isomer (II), forms no stable HCl salt; it gives no diazonium compd. with HNO_2 . Unlike II, also, its soly. in alc. is not increased by the addn. of NaOEt , and *hydrazo-5,5'-di-[2-phenyltetrazole]* (III) does not, like the 1-Ph compd., dissolve in alkalis. 2-Phenyltetrazole-5-carboxyhydrazide, from the Me carboxylate and excess of $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ at 110–20°, m. 200° (decompn.), sol. in dil. mineral acids and in alkalis but not in carbonates, feebly reduces hot $\text{NH}_3\text{-AgNO}_3$, distinctly on addn. of NaOH; *HCl salt*, m. 182° (decompn.), easily loses HCl ; *benzylidene deriv.*, m. 164° (decompn.), sol. in alkalis; *isopropylidene deriv.*, m. 117°. *Azide* (9.7 g. from 11 g. of the azide), m. 100° (decompn.), detonates on Pt or in m. p. tubes over a free flame, is hydrolyzed by boiling H_2O ; the aq. mother liquor yields a small amt. of a substance, m. 167° (decompn.), which is apparently a salt-like compd. of the free acid with the amide into which 2 compds. it can be decompd. and from C_6H_5 solus. of which it can also be obtained. *Et [2-phenyltetrazolyl-5-amino]formate* (IV) (8.1 g. from 10.8 g. of the azide refluxed in alc.), m. 106°, sol. in alkalis. *sym-Di-[2-phenyltetrazolyl-5]-urea* (V) (5.5 g. from 10.8 g. of the

azide refluxed in xylene), yellowish, m. 216° (decompn.). **I** (6.4 g. from 11.6 g. **II** with concd. HCl at 200°), yellowish, m. 142°, also obtained from **IV** with concd. H₂SO₄ at 105–10° and by heating **V** with AcOH and concd. HCl under pressure. *AgNO₃ compd.*, m. 200° (decompn.), deflagrates faintly when rapidly heated over a free flame. **I** dissolves in concd. HCl but seps. from hot 20% acid on cooling. *Benzylidene deriv.*, m. 123° *2-Acetyl amino deriv.*, m. 177° (decompn.), sol. in NaOH, oxidized with loss of the Ac group, by Pegrelon soln. to the azo compd. *Azo-5,5'-di-[2-phenyltetrazole]*, obtained almost quant. from **I** in H₂O with Ca(OCl)₂ on the H₂O bath, canary-yellow, m. 148°, deflagrates faintly on rapid heating over a free flame, evolves gas and becomes red when covered with concd. H₂SO₄, shows in alk. suspension with air or H₂O₂ the same peculiar behavior as the 1-Ph isomer (regeneration of **I**). **III**, from the azo compd. in AcOH suspension with Zn dust on the H₂O bath, m. 184° (decompn.), insol. in NaOH, reduces hot NH₃-AgNO₃ and is easily oxidized back to the azo compd. by Ca(OCl)₂.

C. A. R.

Some derivatives of pyridine. ANTONIO PIERONI. *Atti. accad. Lincei* [6], 2, 125–7 (1925).—Some time ago P. undertook to prep. a series of C₆H₅N (**I**) derivs. analogous to those of C₆H₆ and this is a preliminary report. As in C₆H₆ the substitution of 1 H atom (α) with an NH₂ group renders the substitution of *o*- and *p*-H in **I** easy: thus α -H₂N-C₆H₄N (**II**) resembles PhNH₂. The following derivs. of **I** were prepd. from **II**: α , β '-(H₂N)I, α , β '-ClI, α , β '-Cl(ICI₂) (**III**), α , β '-Cl(IO₂) (**IV**), α , β -(NH₂)NO₂, α , β , β '-(NH₂)-(NO₂)Br, α , β , β '-Cl(NO₂)Br (**V**), α , β '-(NH₂)NO₂, α , β '-(NHAc)NO₂ (**VI**), α , β '-(NHAc)-NH₂ (**VII**), α , β '-Cl(NH₂), α , β '-Cl(N:NC₁₀H₂OH) (**VIII**), α , β '-Cl(NHNH₂) (**IX**), α , β '-Cl(NHN:CHPh) (**X**). The numbered compds. are new. The other were prepd. by modifications of methods of Chichibabin which will be fully described in another paper. α , β '-C₆H₄NCII adds Cl in CHCl₃, giving *dichloroiodochloropyridine* (**III**), yellow, m. 115° (decompn.). **III** in **I** treated with some H₂O pptd. the *iodoxy deriv.* (**IV**), explodes at 205°. From α , β -C₆H₃N(NH₂)NO₂ C₆H₃NCl(NO₂) was obtained in good yield and on reduction with Fe or Sn + HCl gave the corresponding amine. This on diazotization was coupled with β -naphthol and gave α -chloro- β '-azopyridyl- β -naphthol (**VIII**) red, m. 185°. **VIII** with SnCl₂ gave α -chloro- β '-hydrazinopyridine (**IX**), m. 127°, reduces Fehling soln. **IX** with BzH gave the corresponding *hydrazone* (**X**), m. 208°. Probably if the corresponding Br or I deriv. had been used the unsubstituted pyridylhydrazine would have been obtained.

E. J. WITZEMANN

Condensation products of α -aminopyridine with aliphatic-aromatic ketones. I. L. SCHMID AND B. BANGLER. *Ber.* 58B, 1971–3(1925).—All attempts to condense α -C₆H₄NNH₂ (**I**) with PhCOMe failed, but when **I** is refluxed 50 min. with 3 parts PhC(OEt)₂Me there is obtained 32.5% of a condensation *product* (**II**) (80% if the unchanged portion of the reaction mixt. is treated again in the same way), thick yellow oil, *b*₁₁, 174° (the vapor shows a light green-yellow fluorescence), unstable towards acids and alkalies and even on long standing in moist air decomps. into its components, especially if warmed; *HCl salt*, quickly deliquesces in the air; *methiodide*, yellow, m. 162°; *methosulfate*, m. 188°. With HCl gas at 180–204° **II** yields no quinoline but exclusively the *dynpnone deriv.*, m. 118.5°; *HCl salt*, m. 235°; *methiodide*, m. 201–2°. Heated with PhC(OEt)₂Me at 300° and then distd. *in vacuo*, **I** yields a fraction *b*₁₁ 245° and solidifying in the receiver, but its compn. does not correspond to that of the expected methylphenylnaphthyridine.

C. A. R.

Reaction of quinolinic anhydride with aromatic hydrocarbons and aluminium chloride. C. M. JEPHCOTT. *Trans. Roy. Soc. Can.*, Sec. III (3), 19, 28(1925).—C₁₀H₈ in C₆H₆ gave 22% of α -naphthoypicolinic acid, m. 155°, and the β -isomer, m. 145°. The HCl salt and the Me ester of each acid was prepd. Acenaphthene in C₆H₆ gave 10% of 4-acenaphthoypicolinic acid, decomp. 168–70° and does not form a HCl salt. A hydrate, m. 121° and a Me ester, m. 112–4°, were prepd. J. W. SHIPLEY

Constitution of corycavidine and corycavamine. F. v. BRUCHHAUSEN. *Arch. Pharm.* 263, 570–602(1925).—The present investigation substantiates the findings of Gadamer respecting the empirical compn. of corycavidine, *vis.* C₂₂H₂₄O₈N, and justifies its assignment to the corycavine group. Contrary to the behavior previously observed in 10-ring nuclei no rearrangement to a quaternary iso-compd. resulted from treatment with AcCl. Methylation and cleavage of corycavidine methosulfate by means of Na-Hg in acid soln. yielded optically active tetrahydromethylcorycavidine, C₂₂H₃₁O₈N. On evapn. with HCl it lost the elements of H₂O, yielding optically inactive anhydrotetrahydromethylcorycavidine, C₂₀H₂₉O₈N, which latter on oxidation with KMnO₄ gave methylacetoveratrone, C₁₀H₁₄O₃, *N*-methylhydrastinine, C₁₂H₁₅O₃N, methylveratric acid, C₁₀H₁₂O₄, 4,5-methylenedioxy-2- β -dimethylaminoethylbenzoic acid and a high mol. acid, m. 243°. From these cleavage products the formula of anhydrotetrahydro-

methylcorycavidine is established, as also indirectly that of corycavidine disclosed. Starting from *o*-cresol, methylacetoveratrone and methylveratric acid were prepd. synthetically, as also through degradation of corydaline. Reduction of corycavidine with Na-Hg leads to the formation of dihydrocorycavidine, $C_{22}H_{27}O_5N$, which is converted by $AcCl$ into isodihydrocorycavidine chloride, $C_{22}H_{26}O_5NCl$. Alc. KOH resolves the latter into anhydroisodihydrocorycavidine, identical with des-*N*-methyl-4-methyltetrahydroberberine prepd. from berberine. Optically active corycavamine is the desmotropic form (keto) of corycavine (enol.). W. O. E.

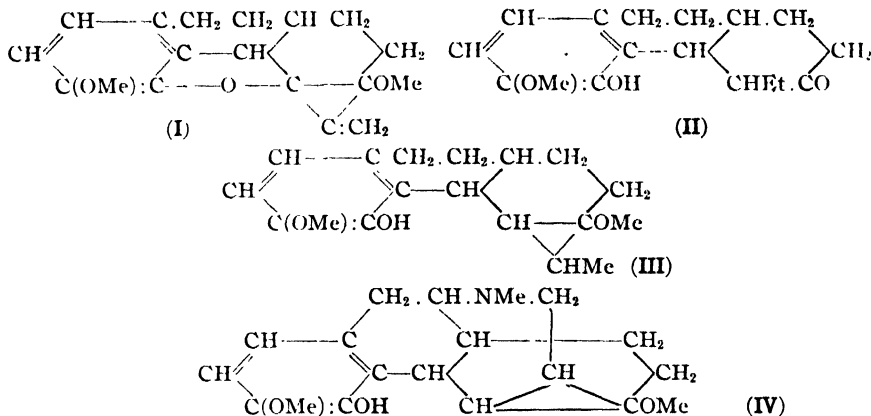

Alkaloids of *Corydalis cava*: corybulbine and isocorybulbine. F. V. BRUCH-HAUSEN AND KATSUJI SAWAY. *Arch. Pharm.* **263**, 602-5(1925).—Because of an identical study by Späth and Dobrowsky (cf. *C. A.* **19**, 2959) further work in this direction was discontinued. The methyl ethyl ether of nor-*m*-hemipinic acid obtained by S. and D. was prepd. in a different manner. Starting, *viz.*, from creosol and Et_2SO_4 , creosol Et ether was obtained and converted *via* Friedel-Craft into 3-methoxy-4-ethoxy-6-acetotoluene, $C_{12}H_{16}O_3$, needles, m. 50-1°, b_{11} 156-60° (oxime, m. 99-100°; semicarbazone, m. 185-6°), which latter on oxidation in Na_2CO_3 with $KMnO_4$ gave 1-methyl-3-methoxy-4-ethoxy-6-benzoic acid, $C_{11}H_{14}O_4$, needles m. 180-3° (*Me ester*, needles, m. 64-5°) and 1-methyl-3-methoxy-4-ethoxy-6-benzoylformic acid, $C_{12}H_{14}O_6$, needles, m. 75-7° (*Me ester*, m. 108-9°), which latter with H_2O_2 and alkali is converted smoothly into the former. On further energetic oxidation with $KMnO_4$ methyl ethyl ether of nor-*m*-hemipinic acid, m. 184-5° resulted. W. O. E.

Aconitum alkaloids. IV. Oxonitine and some new derivatives of it. RIKO MAJIMA AND HARUSADA SUGINOME. *Ber.* **58B**, 2047-51(1925); cf. *C. A.* **19**, 291. The various samples of oxonitine (I) prepd. from japonitine A, A_1 , A_2 , B, B_1 and aconitine A and C, are identical in compn., decompn. p. and rotation, contain 3 MeO groups and no MeN group. Heated up to the decompn. p., all the samples of I lose 1 mol. $AcOH$ and yield the same pyroxonitine (II) which very probably has the compn. $C_{23}H_{29}O_8N$; I would therefore be $C_{23}H_{33}O_{10}N$. II is very easily hydrolyzed by $Ba(OH)_2$, yielding $BzOH$ and, almost quant., pyroxonine (III), $C_{16}H_{23}O_5N$. The various I decomp. 282°, $[\alpha] -41.0^\circ$ to -42.7° ($CHCl_3$) and contain 59.44-59.61% C, 6.26-6.38% H. II, m. 231°, seps. from $CHCl_3$ with 1 mol. solvent, $[\alpha]_D^{20} -128.9^\circ$ ($EtOH$), -127.5° to -129.9° ($MeOH$), MeO 20.38%, C 61.06-61.45%, H 6.21-6.57%. N 3.30-3.40, mol. wt. in camphor 450-63. III, decomp. 273-4°, C 58.98-59.34, H 7.14-7.23, N 4.12, MeO 25.8-25.9%, dissolves in about 9 parts abs. alc., is easily turned yellow by the air in alkalis, does not decolorize Br in $AcOH$, reacts absolutely neutral, seps. unchanged from dil. HCl on concn. *in vacuo* over alkali, forms no ppts. with picric acid, $AuCl_3$ or $PtCl_4$. C. A. R.

Constitution of codeine and thebaine. J. M. GULLAND AND R. ROBINSON. *Mem. Proc. Manchester Lit. Phil. Soc.* **69**, 79-86(1925).—Hydroxycodeinone (I) and its dihydro deriv. (II) do not reduce Fehling soln. or NH_4OH-Ag_2O , even on warming; both bases are recovered largely unchanged from solns. in 30% aq. H_2SO_4 after boiling 2.5 hrs. These facts argue against the formulation of I as an α -hydroxy ketone. Bromocodeinone and I yield the same I oxime, m. 279°. I is considered 14-hydroxycodeinone. Structural formulas are suggested for these compds. II condenses with piperonal to form an amorphous yellow powder, $C_{26}H_{28}O_6N$, giving a red soln. in concd. HCl and a purplish red color in H_2SO_4 . The corresponding solns. of the benzylidene deriv. are colorless and red, resp. I gives similar derivs., showing the same color reactions, but analyses indicate the occurrence of reduction as well as condensation. Both I and II condense with *o*- HOC_6H_4CHO , giving the orange-red solns. characteristic of the salts of most salicylidene-ketones. I and 6-aminopiperonal condense with $EtONa$ to give the compd. $C_{26}H_{26}O_6N_2$, crystg. with $1C_6H_6$, m. 243-4°; it gives Gadamer's test and thus contains the CH_2O_2 group. II gives a dihydro-6-aminopiperonaldihydro-hydroxycodeinone, $C_{26}H_{24}O_6N_2$, m. 282-3° (decompn.); the colorless H_2SO_4 soln. does not exhibit fluorescence. C. J. WEST

Morphine alkaloids. IV. Constitution of thebaine. HEINRICH WIELAND AND MUNIO KOTAKE. *Ber.* **58B**, 2009-12(1925); cf. *C. A.* **19**, 2827.—As shown in the earlier paper the N-free ether (I) obtained by the Hofmann degradation of dihydrodes-N-methylidihydrothebaine gives on catalytic hydrogenation with Pd black the ketophenol (II), probably the vinylene group first adding H and the O bridge between the rings then being ruptured, but the intermediate thebaine deriv. (III) seemed to be incapable of existence. On repeating the prepn. of II in alc. freed from every trace of acid by the addn. of a very little $NaHCO_3$, however, III was unexpectedly obtained; on short warming with HCl, it changes into II. Methylation of II gives a *di-Me ether* (IV) isomeric with III. The isolation of III is a further indication that thebaine (V) is not, as repre-

sented in the Knorr-Hörlein formula, an enol ether. Hydrogenation of V in an absolutely acid-free medium gave an oil (VI) with phenolic properties yielding on short warming with 2 N HCl 80% of dihydrothebainone. III (0.75 g. from 1.3 g. I), m. 168–9°, gives with FeCl₃ the green color characteristic of the phenols of this whole group, MeO content 20.92%. IV (0.3 g. from 0.5 g. II with alk. Me₂SO₄ in aq. alc.), m. 111–2°, gives no color with FeCl₃, is stable towards KMnO₄ in Me₂CO; benzal deriv., m. 128–30°. Hydrogenation of I as described in the earlier paper gives only about 33% II; the greater part of the product is a viscous isomer, b₄ 180–5°, which likewise gives the green FeCl₃ reaction.

C. A. R.

Aluminioxalates of some optically active bases. T. B. CHILD, ELWYN ROBERTS AND E. E. TURNER. *J. Chem. Soc.* 127, 2971–2 (1925).—Attempts to resolve compds. derived from H₃Al(C₂O₄)₃ by the use of active bases were unsuccessful. *Strychnine aluminioxalate*, needles with 16 H₂O, α_D²⁰ –24° to –21° in 50% aq. Me₂CO; on recrystn. partial decompn. occurred. A sample prepd. from Na₃Al(C₂O₄)₃ showed α_D²⁰ –19°. *1-Methylamine aluminioxalate*, prisms with 1H₂O, α_D²⁰ –28.5° in 50% aq. Me₂CO. The *1-phenylethylamine* salt forms prisms with 1H₂O, α_D²⁰ –3.0° (H₂O). The *distrychnine K* and *d-phenylethylamine K₂* salts were also prepd., but in no instance was a change in sp. rotation observed after repeated crystn.

C. J. WEST

Resin acids. III. K. SUZUKI. *J. Pharm. Soc. Japan* No. 524, 888–95 (1925); cf. C. A. 19, 2501.—Further studies on the properties of densipimaric acid (I) and its derivs. I in solns. undergoes progressive changes in optical rotation, their extent depending upon the nature of the solvents. About 7% I in 96% alc. gives after 0, 11, 26, 38, 49 days [α]_D^{18–20} –63.1°, –59.3°, –48.2°, –42.6° and –36.1°; in 86% alc., after 0, 5, 10, 16, 31, 64 days, [α]_D^{20–22} –57.9°, –51.8°, –51.2°, –46.7°, –43.1° and –41.1°; and about 8% I in CCl₄ soln. after 0, 17, 38, 49, 64 days, [α]_D^{18–20} –41.40°, –43.9°, –34.2°, –25.3°, +2.8°. These solns. were left in the dark (18–22°), protected from air. The cause of these changes, which, S. is sure, are not to be due to an impurity at least, was not explained. When I is treated with dil. alkalies and optical sepn. is effected, 2 acids are obtained: α-acid, m. 173°, [α]_D²⁴ –4.5°; β-acid, m. 153–6°, [α]_D²⁴ –9.5°. These two are probably isomers of I, produced by the action of alkali on I. With HBr, is formed a di-Br. deriv., m. 174–5°, identical with the dibromohydroabietic acid of Levy and Ruzicka (C. A. 7, 2388; 16, 2500). Dihydrodensipimaric acid (II), previously reported to m. 182–3°, after repeated recrystn., m. 207°, a trace of impurity makes it 190°. By catalytic hydrogenation, I also gives another compd. (III), m. 172–3°. When II is heated with a mineral acid, it gives a substance, m. 173–4°, which is not the same as III, but is very similar to the dihydroabietic acid of Virtanen and Johanson. When abietic acid prepd. from I is hydrogenated, it yields a dihydroabietic, m. 141–3°, [α]_D²⁰ –7.7°, which when heated with HCl in sealed tubes goes over to a compd., m. 160–4°.

S. T.

Lignin compounds. K. KÜRSCHNER. *Brennstoff-Chem.* 6, 304–11 (1925).—The conclusion of a series on this subject (cf. C. A. 19, 3487). K. regards lignin as mainly a

colloidal coniferin complex on which free coniferin is to some extent adsorbed. This view is based on the similar chem. behavior of coniferin, and lignin (as prepd. by the HCl extn. process). A large no. of reactions which both lignin and coniferin give are cited. Important ones are: 1. Hydrolysis of coniferin and lignin to coniferyl alc. and glucose, the former being readily oxidized to vanillin and vanillic acid. 2. Identical color reactions with HCl and phloroglucinol. 3. Soly. in $\text{CCl}_3\text{CO}_2\text{H}$. 4. Similar products obtained on fusion with alkalis—protocatechuic acid, humic acid, etc. 5. Similar sulfo acids are formed by digestion in sulfite soln. Furthermore the C, H and Me content of lignin indicate it to be a coniferin complex. J. D. DAVIS

Constituents of the yew leaves. II. H. KONDO AND T. TAKAHASHI. *J. Pharm. Soc. Japan* No. 524, 861-76(1925).—Further studies on the constitution of texin (I) It was prepd. according to the method given in *C. A.* 17, 2442. Preliminary examn. shows that it has 2 NMe_2 , and no MeO groups. When it is acetylated by heating with Ac_2O , a yellow amorphous Ac deriv. is produced which contains 5 Ac groups, showing the presence of 3 OH. Since its methiodide has the compn. $\text{C}_{37}\text{H}_{61}\text{NO}_{10}\text{MeI}$, it must be a tertiary amine. When it is boiled on the water bath with 30 times its vol. of 0.2 *N* alc. KOH, a neutral, yellow amorphous nitrogenous substance (II), a cryst. substance (III), insol. in Et_2O , m. 286° , and HCO_2H , AcOH, citric and a powdery acid are formed. II, $\text{C}_{21}\text{H}_{35}\text{NO}_5$ $[\alpha]_D^{25} -45.51^\circ$, is named *taxinolamine*. An amorphous acid $\text{C}_{16}\text{H}_{24}\text{O}_6$ obtained by decompn. of II, is named *taxic acid* (IV) and has $[\alpha]_D^{20} -49.29^\circ$. II has at least 3 OH groups, gives no reaction with $\text{H}_2\text{NCONHNH}_2\cdot\text{HCl}$, $\text{NH}_2\text{OH}\cdot\text{HCl}$, $\text{PhNHNH}_2\cdot\text{HCl}$ or with phloroglucinol- H_2SO_4 . It does not form iodoammonium base with MeI even in a sealed tube. Thus of the 5 O atoms in II, 3 are in OH groups, but the others are not in C:O, or CH_2O_2 groups. When the Ac deriv. of II is oxidized in glacial AcOH with KMnO_4 , a compd. $\text{C}_{21}\text{H}_{26}\text{NO}_6(\text{COME})_3$ is obtained. When oxidized similarly at a high temp., a compd. $\text{C}_{20}\text{H}_{26}\text{NO}_6\text{Ac}_3$ is obtained. When $\text{I}\cdot\text{MeI}$, suspended in H_2O is decompd. by AgOH , Me_3N and an amorphous compd. $\text{C}_{35}\text{H}_{44}\text{O}_{10}$ (V), $[\alpha]_D^{20} 50.72^\circ$, are obtained. If V is decompd. with 0.2 *N* alc. KOH, it gives AcOH, citric acid, IV (m. $92-5^\circ$, and effervesces at 130°) and a neutral substance (VI), m. $94-5^\circ$, $\text{C}_{19}\text{H}_{24}\text{O}_6$, corresponding to II minus Me_2NH and named *taxinol*. From these, it is concluded that I is the ester of II and a hydrate of IV and VI is an unsatd. alc. produced by removing Me_2NH from II. Thus $\text{C}_{37}\text{H}_{51}\text{NO}_{10}$ (I) = $\text{C}_{16}\text{H}_{21}\text{O}_6\cdot\text{C}_{19}\text{H}_{24}\text{O}_6\text{NMe}_2 = \text{PhCH}(\text{CHC}_6\text{H}_4\text{O}_6\text{C}_{11}\text{H}_{14}\text{O}_2(\text{NMe}_2)(\text{OH})_3[(\text{CH}_2)_2\text{Ph}])$. S. T.

Further results in the study of the structure of proteins. EMIL ABDERHALDEN. *Naturwissenschaften* 13, 999-1000(1925).—A review pertaining to A.'s recent work on the properties and desmotropic forms of 2,5-diketopiperazines (cf. *C. A.* 19, 39, 79, 994, 2830, 2809, etc.). B. J. C. VAN DER HOEVEN

Halogenated proteins. V. Bromocasein. A. J. J. VANDEVELDE. *Rec. trav. chim.* 44, 900 6(1925); cf. *C. A.* 19, 2502.—Bromocasein (I) was mentioned in previous papers (*C. A.* 18, 2134; 19, 818). In prepn. A 150 g. pure Poulenc casein (14.8% N) was treated with 3 cc. Br_2 in 100 cc. CCl_4 for 35 days at room temp. 22 g. I was obtained with 32.3% Br. In the prepn. B 50 g. dry casein were treated with 10 cc. Br_2 in 300-cc. CCl_4 for 65 days and gave 77.3 g. I with 35.2% Br. I is yellow, finely granular and little hygroscopic; only traces of HBr are present, which indicates that I is an addn. and not a substitution product. 3 g. A treated with 50 cc. H_2O for 8 days at 18° left an insol. residue (1.5 g.) with 12.7% N and 11.6% Br. The same result was obtained with B. In the filtrate by treatment with $\text{HNO}_3 + \text{AgNO}_3$ it was found that only 7.7% of the total Br originally present is still combined organically. By expts. at 61° these results were confirmed and extended. The N content of the insol. portion is nearly const.; the Br content varies through a small range. The Br organically combined decreases as the duration of the action of H_2O is lengthened. When the amt. of H_2O is diminished, the amt. of insol. Br product increases and the amt. of organically combined Br diminishes. 5.4 g. A treated 8 days at room temp. with 100 cc. 0.5 *N* KOH is completely dissolved. On adding 60 cc. 1.0 *N* AcOH 2.9 g. of a product contg. 12.65% N and 8.45% Br is pptd. 5 g. B in 100 cc. 95% EtOH for 5 days gave 3.1 g. insol. product contg. 12.2% N and 14.7% Br. Only 2.7% of the total Br was organically combined in the sol. part. A heated 10 hrs. at 100° lost 8% Br and gave a product that behaved much like the unheated material toward H_2O and KOH. In attempting to develop an interpretation of this addn. of Br to proteins Vandeveld has obtained a *bromoleucine* contg. 49.3% Br and a *bromotyrosine* contg. 57.29% Br by similar methods. Other bromoamino acids are in prepn. E. J. WITZEMANN

Anomalies of nucleic acid salts. E. PRISER. *Ber.* 58B, 2051-4(1925).—Pure cryst. guanylic (I), adenylic (II), inosinic (III), cytosylic (IV) and uracylic (V) acids were

converted into the corresponding salts by neutralization with brucine and strychnine. These salts can be recrystd. unchanged from H_2O , but if they are extd. with $CHCl_3$, the $CHCl_3$ even at room temp. removes 0.5 of the base from the brucine salt of I and all of it from the salts of II and III. The strychnine salt of II shows the same property but that of I holds both strychnine mols. firmly. Of IV and V the neutral brucine salts are stable towards $CHCl_3$, even on hot extn. for days. C. A. R.

Lipoids. XX. Hypocerebric acid ("Hypohirnsäure"), a new triaminomonophosphatomonosulfatide from the human brain. S. FRANKEL AND O. KARPFFEN. *Biochem. Z.* 157, 414-24 (1925).--A C_6H_6 -insol. compd. $C_{101}H_{152}N_3PSO_{26}$ (I) is isolated from the brain. Upon hydrolysis it gives H_2SO_4 , H_3PO_4 , aminoethyl alc., glycerol and α -hydroxy-decanic acid, m. 161° . The following derivs. of the latter are prepd.: Me ester, m. 102° ; acetate of the Me ester, m. 123° . The Ag salt does not melt; and the Ba salt sinters 205° . The free acid upon oxidation with $KMnO_4$ gives pelargonic acid. All 3 N atoms in I are present in NH_2 groups. W. D. LANGLEY

ISLER, HANS: Ueber Phosphin-methylene. Ueber eine neue Gruppe von farbigen Halogenverbindungen aus Phosphinmethylenen. Weida (Thür.): Thomas & Hubert. 89 pp.

Organic "percompounds." NAAMLLOOZE VENNOOTSCHAP INDUSTRIEEL MAATSCHAPPIJ VOORHEEN NOURY & VAN DER LANDE and J. C. L. VAN DER LANDE. *Brit.* 234,163, Feb. 12, 1924. Org. peroxides or other percompds. such as benzoyl, cinnamyl or acetyl peroxides, peracetic and perpropionic acids, persalts and peraldehydes or other highly oxidized org. compds. are rendered safe to handle by mixing them with inert materials such as inorg. oxides, carbonates, phosphates, chlorides, sulfates or silicates of Mg, Ca, Na, K or NH_4 or with acetates, lactates, citrates or tartrates of Ca, Na, K or NH_4 or with flour.

Hydroxyalkyl sulfides. G. KRANZLEIN and M. CORELL. U. S. 1,570,262, Jan. 19. $(CH_3CH(OH)CH_2)_3S$ is prepd. from $CH_3CH(OH)CH_2Cl$ and alkali sulfides. It is readily sol. in H_2O and has a high solvent power for many org. dyes so that it can be used in dye printing. The sulfide which is produced from a mixt. of $CH_2(OH)CH_2Cl$ and $CH_3CH(OH)CH_2Cl$ by treatment with alkali sulfides (and which is probably a mixt. of simple and complex sulfides) has similar properties.

Methanol. A. MITTASCH and M. PIER. U. S. 1,569,775, Jan. 12. Reaction of CO and H to produce CH_3OH is effected under pressures above 50 atm. (in one example 220 atm.) and at temps. of 250 - 600° in the presence of catalysts such as an equi-mol. association of oxides of Cr and Mn in granular form. Fe is excluded from the catalyst, the walls of the app. in contact with the reacting mixt. and from the reacting materials themselves. Among the catalysts which may be used are oxides of V, U, Al or other oxides which are non-reducible under the conditions of working, or metals such as Cu, Ag, Pb or Zn in conjunction with a metal oxide or a metal salt acting as a promoter, especially those derived from metals of the fourth to seventh groups of the periodic system. Alloys of Cr, Mn, Cu and Zn are referred to as suitable. Cf. C. A. 20, 209.

Ethylating amines. A. R. CADE. U. S. 1,570,203, Jan. 19. $PhNH_2$, or other amine to be ethylated is treated with an Et sulfate under ethylating conditions in the presence of $Ca(OH)_2$ or other alk. compd. of an alk. earth metal which serves to promote the desired reaction.

Acetic anhydride. R. MEINGAST and M. MUGDAN. U. S. 1,570,514, Jan. 19. Vapors of $HOAc$ are heated to 400 - 800° in the absence of base metals and metal oxides, to form Ac_2O .

Hexamethylenetetramine. S. KARPEN & BROS. *Brit.* 234,192, Feb. 26, 1924. Methylene chloride is caused to react with NH_3 under pressure at an elevated temp. NH_3 is preferably used in excess and after the reaction the excess NH_3 is distd. off and the residual material treated with a solvent such as $CHCl_3$ or CCl_4 to dissolve the $(CH_2)_6N_4$.

Anthracene and carbazole. VEREIN FÜR CHEMISCHE UND METALLURGISCHE PRODUKTION. *Brit.* 233,734, May 12, 1924. Crude anthracene is freed from carbazole by heating with caustic alkali in the presence of an inert solvent such as paraffin, b. 260 - 320° , without distg. off the H_2O formed. The "alkali carbazole" is sepd. and converted into carbazole, and the $C_{14}H_{10}$ is crystd. and washed with C_6H_6 .

Esters. SOC. ANON. DES DISTILLERIES DES DEUX-SEVRES (formerly Soc. Ricard, Allenet, et Cie). *Brit.* 234,458, May 24, 1924. In forming esters of aliphatic or aromatic acids continuously, an equimol. mixt. of the alc. and acid is supplied continuously from a const.-level tank to a boiler contg. a quantity of the alc. and acid together with a catalyst such as benzenesulfonic acid, H_2SO_4 or HCl , heated to the b. p. With esters

of "medium" volatility such as Pr, Bu and Am formates, Et, Pr, Bu and Am acetates, Me, Et and Pr propionates, Me and Et butyrates and Me valerate, the H_2O produced in the esterification forms with the ester a const. boiling mixt. which may be removed by distn. Details of EtOAc manuf. are given.

Sulfonating β -naphthol. M. L. CROSSLEY and G. S. SIMPSON. U. S. 1,570,046, Jan 19. In sulfonating β -naphthol with H_2SO_4 , an O-contg. B compd such as H_3BO_3 or a borate is added and serves to increase the yield of the product.

The influence of the cultivation of yeast on galactose on the fermentability of this carbohydrate by the yeast. II. EMIL ABDERHALDEN. *Fermentforschung* **8**, 474-8(1925); cf. *C. A.* **18**, 3389.—The cultivation of yeast cells on galactose results in an increase in the galactose-fermenting power, and this when once acquired persists for a long time. It is not impaired when the yeast cells are dried, and it survives the subsequent cultivation of the yeast on solns. of other carbohydrates. A. W. DOX

The affinity relations of sucrase. V. The specificity of sucrase and raffinase action. KARL JOSEPHSON. *Z. physiol. Chem.* **149**, 71-93(1925); cf. *C. A.* **20**, 214.—The cleavage of sucrose is inhibited by α -methylglucoside to a much greater extent than that of raffinose, but is independent of the concn. of substrate. In view of the evidence in favor of the identity of sucrase and raffinase, the probable explanation of this difference in inhibition is an unequal binding of the 2 substrates to the enzyme. Inhibition by β -methylglucoside is, however, practically the same for the 2 sugars. Salicin, on the other hand, exerts a greater inhibition on raffinose than on sucrose cleavage, and in this respect resembles the simple sugars. Both glucose and fructose show a smaller inhibition in the presence of α -methylglucoside. The inhibition by glucose, but not that by fructose, is diminished by the presence of salicin; hence the glucoside possesses no affinity toward the fructose-binding group of the enzyme. Addn. of EtOH does not change the reactivity of the enzyme toward the simple sugars. A. W. DOX

Gluco- and fructo-sucrase. RICHARD KUHN AND HERBERT MÜNCH. *Z. physiol. Chem.* **150**, 220-42(1925).—On the basis of the inhibitory effect of cleavage products on the velocity of sucrose cleavage, 12 sucrase solns. prepd from various yeasts are classified into 4 groups: (1) those inhibited much more feebly by α - than by β -glucose and inhibited by fructose, (2) those inhibited by fructose but not by α - or β -glucose, (3) those inhibited by α - and β -glucose but not by fructose, (4) those inhibited by all 3 hexoses. Yeast sucrase therefore behaves sometimes as gluco- and sometimes as fructo sucrase. The yeast enzyme cannot be sharply differentiated as fructo-sucrase in contrast to the gluco-sucrase which occurs in other fungi and in animal secretions. The 4 types may be regarded as variable mixts. of 2 sucraes of different specificity, either mixts. of a gluco- and a fructo-sucrase or mixts. of 2 enzymes sp. for α - and β -sugars. A simpler explanation would be the assumption of the presence of accompanying substances which influence the sp. inhibitions of a single enzyme. A further possibility is a differentiation between 2 enzymes, 1 of which exhibits affinity for the amylenic oxide and the other for the butylene oxide structure of the sugar. A study of the effect of a purified yeast enzyme of type I (fructo-sucrase) and an enzyme prepn. from *Aspergillus oryzae* (gluco-sucrase) toward hesperonal (sucrosephosphoric acid) showed that the yeast enzyme hydrolyzed the sucrose without liberation of H_3PO_4 , whereas the mold enzyme liberated H_3PO_4 more rapidly than it hydrolyzed the sucrose. Both observations indicate that the H_3PO_4 in hesperonal is esterified with the glucose moiety of the disaccharide. Partial hydrolysis by HCl also gave chiefly fructose and glucosephosphoric acid. The isomeric glucofructosephosphoric acid is probably present also, since hesperonal is not an individual substance, and this accounts for the fact that yeast sucrase gave a cleavage of only 30%. A. W. DOX

Coproporphyrin synthesis by yeast and factors which influence it. III. Coproporphyrin ester from pure cultures of *Saccharomyces anamensis*. HANS FISCHER AND

HERMANN FINK. *Z. physiol. Chem.* **150**, 243-60(1925); cf. *C. A.* **19**, 2509.—The earlier evidence of coproporphyrin synthesis by yeast was not entirely conclusive because of the possibility that coproporphyrin or some precursory substance may have been supplied by the culture medium or by the relatively large amt. of yeast used for inoculation. The objection has now been met by expts. in which only a loopful of pure culture was used for inoculation and grown on coconut milk or ext. of shredded coconut. Coproporphyrin was thus demonstrated satisfactorily. The amt. was not further increased by the addn. of blood to the culture medium, showing that the substance results from an actual synthesis. From *Saccharomyces ananensis*, a yeast which requires no vitamin addn., a sufficient amt. was obtained for the prepn. of the ester in cryst. form. Other organisms, e. g., *Aspergillus oryzae*, saké yeast and tubercle bacilli, also synthesized coproporphyrin when cultivated on a coproporphyrin-free medium. From the evolutionary standpoint coproporphyrin is therefore the oldest form of blood pigment. The fact that the Fe complex does not occur in these lower forms is striking. Synthesis is favored by a temp. of 18-25° and a sugar content of 10%, but retarded by aeration. Addn. of various amino acids and pyrrole derivs. was without influence. A. W. D.

Porphyrins from blood pigment. III. ARNO PAPENDIECK. *Z. physiol. Chem.* **150**, 261-6(1925).—The prepn. of α -hematoporphyrin from hematin by treatment with $N_2H_4 \cdot H_2O$ -AcOH to remove Fe may be improved by allowing the reaction to proceed for a longer time at room temp. instead of water bath temp. The formation of a green pigment is thus diminished and the HCl salt of the porphyrin is obtained in cryst. form by treatment with Et_2O -HCl and $CHCl_3$. The $CHCl_3$ should be $EtOH$ -free in order to avoid esterification. The porphyrin contains 2 esterifiable carboxyls and the unsatd. side chain of hematin, and is identical with Küster's hematerindicarboxylic acid. A. W. DOX

Invertase. XI. Diminution of invertase in yeast. RICHARD WILLSTATTER AND CHAS. D. LOWRY, JR. *Z. physiol. Chem.* **150**, 287-305(1925); cf. *C. A.* **19**, 3194.—As certain maltase-free yeasts have the power of fermenting maltose directly without intervention of the hydrolytic enzyme, so it is possible to ferment sucrose directly under conditions which preclude a preliminary hydrolysis by invertase. Dil. alkalis and acids diminish the sucrose content of yeast without killing the organism and the fermenting power remains practically unimpaired. Without appreciable change in fermenting power the invertase content may be increased 15-20 times or diminished 30 times its original value by suitable treatment. The presence of 0.15-0.30 *N* H_2SO_4 or 0.05 *N* NaOH during 1 hr. destroys 95% of the invertase leaving the fermenting power practically unaltered, the only difference being a lengthening of the induction period. Invertase is, however, formed during the fermentation. By allowing the fermentation to proceed at p_H 2 the fermentation is retarded only 20-30% while the invertase action is diminished to 7% of its normal value. Fermentation then proceeds more rapidly than hydrolysis. A. W. DOX

The action of hydrogenase in the presence of peroxides. J. GRÜSS. *Wochschr. Brau.* **42**, 223-4(1925).—The theory of fermentation advanced in *C. A.* **19**, 3094, is further discussed. The reactions are comparable to those of the inversion of cane sugar by HCl, in which H_2O is added to sucrose and HCl regenerated. Invertin probably acts in an analogous way and must contain a H ion when in soln. Hydrogenase must act in a similar manner. To test this theory the following solns. were prepd.: 300 cc. H_2O , 2.5 g. peptone, 0.5 g. asparagine, 0.3 g. K_3PO_4 , 0.3 g. $MgSO_4$, 0.3 g. KNO_3 , 0.1 g. NaCl, 0.3 g. $Ca_3(PO_4)_2$, 45 g. glucose. To one-half of this soln. (a) 3 g. yeast was added, and to the other half (b) 3 g. yeast, 12 g. MnO_2 and 10 cc. 3% H_2O_2 . When fermentation was completed the following results were obtained: Soln. a yielded 3.283 g. CO_2 , 8.5 g. alc.; soln. b, 2.379 g. CO_2 , 10.5 g. alc. The excess of CO_2 produced in a may be explained by assuming that dihydroxyacetone is produced from glucose, which is oxidized to H_2O and CO_2 . C. N. FREY

Further investigations of the physical properties of serums by the addition of substances which combine with water. R. FÜRTH AND R. PECHHOLD. *Kolloid-Z.* **37**, 193-9(1925).—By methods which were identical with previous investigations (cf. *C. A.* **18**, 1508, 1837) the viscosity, cond. and refractive index of blood serum of cattle have been shown to change with the addn. of MeOH, iso-PrOH and acetone in a manner entirely analogous with that of EtOH. The discrepancy between the observed results of the authors and those of Hayashi (cf. *C. A.* **19**, 2346) is attributed to a difference in methods. By increasing the diln. of the serum with H_2O the min. of viscosity obtained by addn. of MeOH was gradually effaced and completely disappeared at dilns. of more than 10%. This confirms the former explanation on the basis of the dipolar theory of Debye. Also in *Biochem. Z.* **164**, 9-17(1925). H. M. McLAUGHLIN

The human organism as an energy system. W. A. WHITE. *Ann. Clin. Med.* **4**, 285-92(1925).—A study of the distribution of energy and stresses in the body.

JOHN T. MYERS

The kinetics of agglutination of red blood cell suspensions. JEAN OLIVER AND PEARL SMITH. *J. Phys. Chem.* **30**, 1-11(1926).—The formulas of Smoluchowski (*C. A.* **11**, 3140) were successfully applied to the rapid agglutination of red blood corpuscles at their isoelec. point. The agglutination does not follow the course of a mono-, bi- or tri-mol. reaction but does follow that observed in pptn. of colloids. The blood cell must have a larger radius of attraction than that of a colloidal particle, to account for the fact that agglutination proceeds almost as fast as colloidal pptn. D. S. VILLARS

Surface composition of normal and sensitized mammalian blood cells. STUART MUDD AND EMILY B. H. MUDD. *J. Exptl. Med.* **43**, 127-42(1926); cf. *C. A.* **19**, 92.—The interfacial tension method has been applied to the study of the surface composition of mammalian blood cells and to certain other particles. Unsensitized erythrocytes and stromata possess only a small margin of stability in the interface and pass readily into the oil phase. Specifically sensitized erythrocytes and stromata possess much greater stability in the interface and pass into the oil only with considerable mechanical aid; characteristic deformations of the erythrocyte surface or the interface or both often result. With special immune sera the quant. relations are such as to indicate that the increased polarity of the sensitized erythrocyte surface is due to combination of the red-cell surface lipoids with hemolytic sensitizer. These results are corroborative of the conclusions of Landsteiner and van der Scheer that erythrocytes contain sp. lipid-sol antigens. It is tentatively concluded that with these horse-erythrocyte anti-sera at least the agglutinins combine predominantly with the protein of the red cell surfaces. Fresh human leucocytes are spread and disintegrated by the interfacial stresses. After heat injury the leucocytes typically do not enter the boundary surface. They are pushed before the advancing interface and, if their further advance is obstructed, bend the interface backward to form peninsulas and vacuoles. This change after heating is in the opposite sense to that to be expected from denaturation of the proteins of the protoplasm. Fresh oxalated rabbit platelets pass very easily into the oils. After heating, these elements also become less oil-miscible. The interfacial tension relations of blood cells, bacteria and several cell products are tabulated C. J. WESR

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

"Hemochromogen reactions" of yeast and plant seeds, oxidase reactions and blood test. O. SCHUMM. *Z. physiol. Chem.* **150**, 276-86(1925).—To ascertain whether the chem. and spectroscopic blood tests used in medical jurisprudence may be vitiated by org. Fe complexes present in higher and lower plants, exts. of yeast and plant seeds were tested for the benzidine and the pyridine-hemochromogen reactions. The positive reactions obtained cast some doubt on the specificity of such tests for the identification of blood. The substance which gives the pyridine-hemochromogen reaction is a normal constituent of plants and cannot be attributed to contamination with impurities of animal origin. From yeast and seeds an ext. may be obtained with AcOH and CHCl₃ giving a spectrum which can hardly be distinguished from that of hematin. With the cyan-hemochromogen test yeast autolysate and ext. of putrefied flesh give the same cyan-myochromogen reaction. A. W. DOX

A simple micro-method for the determination of sugar, particularly blood sugar. ERNST KOMM. *Z. angew. Chem.* **38**, 1094-6(1925).—This method depends upon the colorimetric detn. of Cu. Only 0.4 cc. of blood is necessary. The blood is freed from proteins with Na tungstate and H₂SO₄ according to Folin, then heated with Fehling soln.

The Cu_2O formed is isolated by centrifuging, and dissolved in dil. HNO_3 , then an excess of ammonia water is added and the blue soln. formed is compared colorimetrically with a standard soln. prep'd. by mixing a CuSO_4 soln. with an excess of ammonia water. The Autenrieth-Königsberger colorimeter is used. The results agree with those obtained according to the method of Bang

EMIL KLARMANN

Micro-method for titrating the bicarbonate in plasma. E. H. LEPPEP AND C. J. MARTIN. *Biochem. J.* **19**, 573-80 (1925).—Blood is drawn from the ear into a collecting tube made from a piece of glass tube 7 mm. internal bore, sealed at one end and drawn out at the other until the internal bore is about 1 mm. The collecting tube has a small hole near the drawn-out end to permit the air to escape as the blood enters, before use, a few crystals of oxalate and 0.1 cc. liquid paraffin are introduced into it. Draw 0.25 cc. plasma into a graduated pipet and deliver into a 100-cc. flask (with rubber stopper bored to take a test tube) Wash the pipet 3 times with saline soln. Add 1 cc. 40% alc., mix the contents, insert the rubber stopper carrying one of the test tubes, invert the flask so that the contents run down into the test tube, and place in this position in the colorimeter. Place in another test tube 2 cc. phosphate soln. (33.33 cc. 0.2 M KH_2PO_4 , 43.66 cc. 0.1N NaOH , CO_2 -free distd. water to 100 cc.; the soln. has a p_{H} of 7.07) and put in the colorimeter beside the plasma. Add a small quantity of burnt sugar soln. (carefully neutralized) until it matches the color of the plasma. Add another cc. of phosphate and 5-8 drops of neutral red (0.05% in water). Run acid into the flask from a micro-buret until the contents become bright pink. Shake the fluid and frequently change the air in the flask by inserting a piece of wide-bore glass tubing and inhaling through it. As the CO_2 is removed the color of the fluid changes to an orange tint again. Repeat the shaking out process after each addition of acid. As the end point is approached, add single drops of acid and place the stopper in the flask, invert the flask and compare the color of the contents with that of the phosphate tube.

BENJAMIN HARROW

Method for the estimation of glucose in blood. G. A. MILOV. *Biochem. J.* **19**, 746-9 (1925).—Nitroanthraquinone sulfonates are reduced when heated with glucose in alk. soln., first to the corresponding hydroxylamine derivs. having an intense green color, and later to a deep red substance which is probably an amine deriv. Under the conditions of the expt. neither uric acid nor creatinine "seriously affects the glucose values." *Method.*—At least 1 cc. blood is required. Ppt. the proteins by the Folin and Wu procedure (*C. A.* **13**, 2541), the blood is, therefore, dild. 1 in 10. Let the mixt. of dild. blood with sodium tungstate and $2/3\text{N}$ H_2SO_4 stand 30 min., filter and introduce 5 cc. of filtrate into a graduated tube of 15 cc. capacity. Introduce 1.5, 1.8, 2.1, 2.5 and 3.0 cc. of 0.02% glucose into 5 numbered graduated test tubes of 15 cc. capacity and 12 mm. bore. Add to each tube 1 cc. 0.4% aq. 1,5-nitroanthraquinonesulfonic acid and 2 cc. K_2CO_3 (50 g. per 100 cc.). Dil. all the solns. to 10 cc. with water, mix. thoroughly, immerse in boiling water for 8 min., cool and make the vol. of each to 12.5 cc. Compare the red tint of the tube contg. blood filtrate with the colors yielded by the glucose solns. The minimal error in the estn. of a sample of blood contg. 0.1% glucose is 4%.

BENJAMIN HARROW

van den Bergh's reaction. Its mechanism and value for the classification of the forms of icterus. G. FAVILLI. *Sperimentale* **79**, 647-64 (1925).—In icterus caused by ligation of the bile duct in the dog, rabbit and guinea pig the van den Bergh diazo reaction (*C. A.* **15**, 3297) gradually passes from the indirect to the direct form. The reaction can take all 3 forms in the same type of static icterus and in toluylenediamine poisoning in dogs, depending on the time at which it is carried out. These results are explained on the basis of the adsorption of all but small amts. of the bilirubin (I) by the colloids of the serum. The reaction is considered excellent for showing the presence of I in the blood, but not for distinguishing between the 2 principal types of icterus.

M. HEIDELBERGER

The determination of fibrinogen. III. W. STARLINGER AND K. HARTL. *Biochem. Z.* **157**, 283-97 (1925), cf. *C. A.* **18**, 2184.—The detn. of fibrinogen in blood serum by the refractometric, Kjeldahl and gravimetric methods shows that values may be higher by one method than by another, depending upon the nature of the serum, *e. g.*, whether native plasma, salt plasma, or salt serum.

W. D. L.

Simple method for determining sugar in cerebrospinal fluid. J. CSAPÓ. *Biochem. Z.* **157**, 350-3 (1925).—The method is based upon that of Bertrand. $\text{Cu}(\text{OH})_2$ is reduced in an alk. medium to Cu_2O , which is isolated and dissolved in H_2SO_4 and $\text{Fe}_2(\text{SO}_4)_3$. The amt. of FeSO_4 formed due to reduction by the Cu_2O is detd. by use of KMnO_4 . Compared with the method of Bang, the results vary by less than 5 mg. %.

W. D. LANGLEY

The determination of iron and blood pigments in normal tissues and tumors. M. YABUSOE. *Biochem. Z.* **157**, 388-95(1925).—Portions of moist organs (50-200 mg.) are placed in weighed porcelain dishes and dried at 100°, weighed and a drop of HCl and a crystal of KClO_3 are added. The mixt. is then ashed. The residue is dissolved in HCl and KCNS is added. The color developed is compared with standard Fe solns to which HCl and KCNS have been added. The method detcs. 0.01 mg. Fe with an error of 20%. **Blood Pigments.**—About 1 g. tissue is rubbed with sand, acidified with HCl to Congo red and extd. 3 times with MeOH, and the MeOH sepd. with a centrifuge. To the soln. obtained is added 1 g. MgSO_4 and after 5 min. of stirring, the whole is centrifuged. The supernatant liquid is removed, and made up to 20 cc. with HCl in MeOH. The hemin in the alc. is then estd. with a photometer. W. D. LANGLEY

Measurement of hydrogen ions of blood. The syringe as an electrode. E. MISLOWITZER. *Biochem. Z.* **159**, 77-9(1925).—To reduce the loss of CO_2 in blood, the syringe with which the blood is taken is converted to an electrode vessel with a gold electrode. By use of quinhydrone in Ringer soln., accurate p_{H} values may be detd. with 1-2 cc. of blood. W. D. L.

Electrotitration in physiological liquids. I. Determination of chlorides in blood and serum. E. MISLOWITZER AND MARTHE VOGT. *Biochem. Z.* **159**, 80-2(1925).—Potentiometric titration of chlorides in the presence of dissolved protein cannot be made but may be made if the protein in KH_2PO_4 is coagulated by heat. HNO_3 is then added and the electrotitration with AgNO_3 carried out. The analytical results agree well with results obtained by the method of Volhard or of Bang W. D. L.

Determination of phosphoric acid (LE GUYON, MAY) 7.

D—BOTANY

B. M. DUGGAR

Effect of tapping coconut palms for toddy on the copra and oil from subsequent fruiting. H. W. JACK AND J. H. DENNETT. *Malayan Agr. J.* **13**, 302-4(1925) Chem. analysis of 100 nuts from trees which had been tapped show a loss of 8.5% in the wt. of dry meat (copra) and of 12% in the wt. of oil per nut. Tapping, however, stimulates the tree in nut production so that the increased no. of nuts may offset the loss of oil by tapping. The proportion of trees tapped is very small. The phys. consts. of the oil were not affected by tapping. L. W. RIGGS

Composition and appearance of soy-bean plants grown in culture solutions, each lacking a different essential element. J. M. GINSBURG. *Soil Science* **20**, 1-13(1925).—Soy beans were grown in Shives R_2C_2 solution and in 8 modifications of the same in each of which one essential element was omitted. The plants were analyzed for dry matter, Ca, Mg, N and total ash. Careful observations were made on the change in appearance of the plants. The total yields of dry matter in the check and solutions lacking Ca, Mg, K, N, P, S, Fe and K (Na substituted) were 2.30, 0.19, 0.48, 0.33, 0.20, 1.40, 1.30, 1.40 and 1.05 g., resp. Na replaced K rather successfully until blossoming. Plants grown in solns. lacking P produced a few seeds which were not viable. The ash content varied from 8.61% where P was lacking to 18.41% where Mg was absent, as compared with 13.31% for the check. Plants grown in incomplete culture solns. with the exception of those grown without S always absorbed higher percentages of Ca and lower percentages of N and Mg than the checks. When Ca was high Mg and N were always low and vice versa. RICHARD BRADFIELD

Influence of water and salt solution upon absorption and germination of seeds. WILHELM RUDOLFS. *Soil Science* **20**, 15-37(1925).—Corn, watermelon, pea, soy bean, white lupine, wheat, buckwheat, alfalfa and rape seeds were germinated between filter paper, both with and without previous soaking in H_2O and MgSO_4 , NaNO_3 , $\text{Ca}(\text{NO}_3)_2$, NaCl , K_2CO_3 , KCl , KH_2PO_4 , KNO_3 and Shive's 3-salt solns. in concns. ranging from 0.001 to 7.0 atm. osmotic pressure. The relative H_2O absorption, length of roots and shoots, and percent of root injury were detd. Soaking in distd. H_2O was harmful to the germination of all seeds; corn was affected least. All seeds were injured in K_2CO_3 solns. Low concns. of some salts did not decrease germination as much as H_2O but the higher concns. proved harmful. As a whole the results were highly specific as to both kinds of seed and nature of salt. RICHARD BRADFIELD

Lack of nodule formation in a subfamily of Leguminosae. L. T. LEONARD. *Soil Science* **20**, 165-7(1925).—Numerous examns. in the field and in the lab. have failed to reveal nodules on 10 species of the genus *Cassia*. Nodules were found on 24 species of

Acacia but not on *Acacia baileyana*. It is not believed that the failure to produce nodules in these cases is due to lack of the proper organism but probably to the phys. character of the root hairs of the plant which inhibits the entrance of the organisms.

R. BRADFELD

The comparative growth of pineapple plants with ammonia and nitrate nitrogen. G. R. STEWART, E. C. THOMAS AND JOHN HORNER. *Soil Science* 20, 227-41 (1925).—The pineapple plant is capable of assimilating all its N in the form of NH_4 salts. Best growth was made, however, in the nitrate cultures. In the early period of growth the nitrate cultures became more alk. in reaction but later became more acid than the original cultures. The NH_4 cultures always become more acid. Analyses of the nutrient solns. after the plants had grown in them showed that K was absorbed more rapidly than any other element, N was next. Amt. of growth was closely correlated with amt. of absorption. The only difference in the compn. of the plants grown in nitrate and NH_4 was in the Ca and CO₂ content of the ash, both being lower in the NH_4 series.

R. B.

Selective absorption of ions by seeds. WILHELM RUDOLFS. *Soil Science* 20, 249-52 (1925).—Corn and soy-bean seeds were immersed in $\text{N}/175 \text{ Al}_2(\text{SO}_4)_3$ and $\text{N}/170 \text{ Al}(\text{NO}_3)_3$ solns. and the change in p_{H} was followed at frequent intervals by the colorimetric method. The p_{H} values were first reduced very rapidly, reaching a min. of about 4.1 in the $\text{Al}_2(\text{SO}_4)_3$ and 3.6 in the $\text{Al}(\text{NO}_3)_3$ solns., resp., in about 2 min. The acidity then decreased, reaching a const. p_{H} value of 5.8 for the soy bean and 4.3 for the corn in both solns. The initial increase in acidity is considered due to the rapid absorption of the Al ion, which is soon overbalanced by the absorption of the anion. The results are explained on the basis of the amphoteric nature of the seed proteins.

R. BRADFELD

The direct hydration of aliphatic carbon and the carbon dioxide assimilation of plants. F. J. NELLENSTEYN. *Chem. Weekblad* 22, 565-71 (1925); cf. *C. A.* 19, 3188.—The active carbons, carboraffin (I) and C black (II), are easily oxidized by dil KMnO_4 with a spontaneous rise of temp. of 50-60°. The oxidation products are characterized as sugar acids by their phys. and chem. properties and their tendency to molding. Norite (III) reacts less promptly. The products give, in contrast to I and II, the mellitic acid test (euchrone) and yield benzene on distn. with NaOH. This supports the conclusion drawn in the previous paper from the adsorption behavior that I and II are aliphatic, while III is an aromatic C. The ease with which C is hydrated suggests that it may be the first intermediate of CO_2 assimilation in the plant, perhaps in the form of a colloidal soln. and that it is directly hydrated to carbohydrates. The faculty of dead plant material to adsorb and store large quantities of CO_2 makes a similar role of C in the living plant probable.

MARY JACOBSEN

Chemical data on *Lilium tigrinum* Sawl. E. HERRERO DUCLOUX. *Rev. Facultad Ciencias* 3, No. 2, 23-32 (1925).—Only the pollen was studied. The coloring matter seems to belong to the anthoxanthine group. It gives with an Al mordant poor and variable shades on silk and wool. Cotton and flax are not dyed. The 2 absorption bands, one between 675 and 648 μ with a max. at 662 μ , the other from 589 μ to the end of the visible spectrum with a max. at 589 (568) μ , are characteristic. The physiologically active (emetic, purgative and hypnotic) principle is obtained in yellow rhombic crystals from the ether ext. of the dye. Its soly., optical consts., the pptn. and color reactions suggest close relationship to colchecin.

MARY JACOBSEN

Mono- and tri-hydrated calcium oxalate in the plant. ALBERT FREY. *Verh. Naturforsch. Ges. Zurich* 70, 1-65 (1925).—An extensive study of the conditions of formation of the mono- and tri-hydrates of CaC_2O_4 is presented. The 2 salts can readily be differentiated by crystallographic methods. F. shows from the standpoint of the phase rule that in the plant only the monohydrate is stable. The trihydrate is unstable and tends to go over into the monohydrate form. The trihydrate is formed in a solution of low osmotic pressure but satd. with CaC_2O_4 . The stability of the trihydrate is decreased in the presence of Ca ions. Each form of the oxalate is characteristic of a definite anatomical and physiol. unit. The formation of CaC_2O_4 in the plant can be explained on the basis of phys. chemistry.

H. R. KRAYBILL

Alcoholate digestion of wood. BROR HOLMBERG AND STEN RUNIUS. *Svensk Kem. Tids.* 37, 189-97 (1925).—Ground fir wood, free from moisture and crude fat, was analyzed for C, H, OMe group and pentose before and after digestion with Na and HCl in alc. The alc. used was both abs. and 95%; both gave the same result. The evidence indicates that the lignin in wood occurs as an acetylated substance with carbohydrate, the latter as an alc. and the lignin as a carbonyl component. A. R. R.

Tannin occurring in the kino of *Eucalyptus calophylla*. ALEXANDER MCGOOKEN AND I. M. HEILBRON. *J. Pharmacol.* 26, 421-46 (1926).—The historical review is ac-

accompanied by a comprehensive bibliography of 283 references. The kino of *E. calophylla* is believed, on the basis of fractional pptn. expts., to consist of 1 sp. tannin; it yields a tri-Me and a tri-Ac deriv. Oxidation (KMnO_4) of the Me deriv. yields veratric acid; O_3 gave only $(\text{CO}_2\text{H})_2$ as did HNO_3 . Fusion with KOH gives protocatechuic acid and catechol. From these results a possible formula is in part developed.

C. J. WEST

Chemical investigations in regard to citrus. C. F. JURITZ. Union of S. Africa, Department of Agr., *Sci. Bull.* No. 40, 3-22; *Chem. News* 131, 309 (1925).—Mech. and chem. analyses of oranges in various stages of ripeness are given. The deleterious effect of arsenical sprays on the flavor of oranges is shown to be due to changes in their chem. compn. The fruit from sprayed trees had less acid, a higher p_{H} , less sucrose and less sugars than that from the unsprayed. The flavor of the former was more insipid.

J. J. WILLAMAN

E-- NUTRITION

PHILIP B. HAWK

The vitamin problem. T. B. VON HAHN. *Kolloid Z.* 36, 271 (1925); W. WINDISCH. *Wochschr. Brau* 42, 351-5. Substances rich in vitamins lower the surface tension of H_2O much more than substances poor in, or contg. no, vitamins. Hemoglobin can be made to pass through membranes if substances which affect the surface tension are added. It is possible that vitamins B and C are identical.

C. N. FREY

The absorption of copper during the digestion of vegetables artificially colored with copper salts. J. C. DRUMMOND. *Analyst* 50, 481-5 (1925).—It appears that in the digestion of vegetables which have been subjected to "reverdisage" with CuSO_4 , Cu is obtained in a form which is capable of being absorbed in the animal body. Cu thus absorbed is held for some time in the liver and is then for the most part excreted in the urine or feces. Expts. with rats indicate no harm resulting from the absorption of traces of Cu over long periods of time.

W. T. H

Proteins in meat production. Their economic utilization in an adequate ration. E. A. HARTLEY. *Fertilizer, Feeding-Stuffs and Farm Supplies J.* 10, 981-2 (1925).—The functions of the different amino acids in their relation to the growth and development of animals are outlined and discussed.

K. D. JACOB

The nutritive requirements of poultry. J. B. ORR, M. MOIR, A. KINROSS AND G. S. ROBERTSON. *Scottish J. Agr.* 8, 263-9 (1925).—Expts were carried out to det. whether ordinary well-balanced rations, fed to poultry kept under practical conditions, were improved by the addn. of substances reputed to be rich in vitamins. Addn. of cod-liver oil, as a source of vitamin A, in amts. varying from 0.2 to 5 cc. per bird per day did not increase the rate of growth or egg production. There was some evidence that the use of cod-liver oil caused an actual decrease in egg production. Vitamin B in the form of yeast and vitamin C in the form of fruit and vegetable juices did not increase the rate of growth or egg production. However, addn. of 3 to 5% of yeast appeared to stimulate early egg production, but the yearly av. was not affected. Vitamins A and B were beneficial to poultry suffering from malnutrition or fed on poorly balanced rations. The effect of vitamin C under similar conditions was not detd. In order to det. the effect of mineral salts on egg production a mixt. composed of $\text{Ca}_3(\text{PO}_4)_2$ in the form of bone flour 100, CaCO_3 as chalk 40, NaCl 40, S 10, Fe_2O_3 10 and K1 1 part, was fed in varying amts in addn. to a well-balanced mash. In 3 expts. lasting from 5 to 12 months there was a total increase in egg production, over the controls, of 25 to 70%. While there seemed to be a definite stimulation at the beginning of the laying period the influence of the addn. of the salts appeared to be even more evident towards the end. The value of the inorg. constituents of fish meal was shown in 2 expts. in which this material was substituted for bean meal and blood meal, resp.

K. D. JACOB

Mineral nutrients in the rations of dairy cows. J. B. ORR, A. CRICHTON, J. A. CRICHTON AND W. MIDDLETON. *Scottish J. Agr.* 8, 312-8 (1925).—The effect of a mineral mixt. composed of CaCO_3 56, NaCl 28, Fe_2O_3 1 and K1 0.125 parts, and fed at the rate of 85 lbs. per ton of compound cake used in the ration, was detd. on 6 dairy cows, 6 cows also being carried as controls. The av. milk yield and the av. wt. of the calves tended to increase in the second lactation with the cows receiving the mineral mixt., while with the control animals there was a decrease. The health of the animals receiving the mineral mixt. was better than those receiving no minerals, with the exception of delay in cleansing after calving. The work is being continued.

K. D. JACOB

The mineral content of pastures. J. B. ORR, W. E. ELLIOT AND T. B. WOOD. *Scottish J. Agr.* 8, 349-59 (1925).—This investigation was undertaken in an attempt to correlate the chem. compn. of certain pastures with malnutrition diseases of animals.

particularly sheep, grazed thereon. Detns. of the amts. of CaO , P_2O_5 , Na_2O , K_2O , Cl , N and fiber and the calorific value were made on 338 samples from (a) typical Scotch, English and Welsh cultivated and natural pastures from different areas, (b) the Falkland Islands, (c) Romney Marsh and (d) some areas to show seasonal variations. The investigation included analyses of good natural pastures—all grazed, poor natural pastures—grazed, and poor natural pastures—not grazed, from the different areas. The calorific value was fairly const. for all samples examd. The amts. of N and all mineral elements, with the exception of Na , were less in the natural pastures than in the cultivated pastures, and were markedly less in the non-grazed areas of the former than in the grazed. With the exception of Na there appeared to be a definite correlation between the various mineral constituents, samples having a low content of one element tending in general to have a low content of the others. In certain samples it appeared that lack of Ca had limited the power of the plants to utilize Cl . Ca appeared to be the limiting factor in the majority of the pastures. In the analysis of samples from the Falkland Islands it was found that grass near the sea contained appreciably greater amts. of N and all of the essential mineral elements than grass from inland. From the results of feeding expts. with lambs it appeared that both linseed and olive oils had a depressing effect on growth, but cod-liver oil and Ca salts had a marked beneficial effect when added to rations deficient in Ca . The original should be consulted for the variety of analytical data.

K. D. JACOB

Nutritive values and physiological effects of different fats and oils. F. J. McCLEURE AND R. H. CARR. *Am. J. Physiol.* **74**, 70-8(1925).—Mature pigeons tolerate 6.7% cottonseed oil—cod-liver oil, oleic acid, beef tallow or cocoa butter when added to a basal diet of whole wheat gram and mineral supplement. In amts. of 5 cc. a day the first 3 proved fatal. The toxicity seems to depend on sp. factors not indicated by any of the known fat constns. Neither the amt. of fat in the egg nor its constns. seemed to be affected by the kind of fat of the ration. The av. fat content of the pigeon's egg was 4.96%, of the edible portion, 1 no. 176, sapon no. 70.5.

MARY JACOBSEN

Account of progress in dental dietetic research. P. R. HOWE. *Dental Cosmos* **68**, 33-5(1926).—Review of recent work on the influence of the diet on diseases of the teeth and related organs. "Dental disorders are to be considered as fundamentally due to irregular mineral metabolism, which in turn is due in a large part to the character of the diet."

JOSEPH S. HEPBURN

The energy requirements of dairy cows. II. Is net energy or metabolizable energy the more useful index for practical purposes? E. B. MEIGS. *J. Dairy Sci.* **7**, 523-36(1925).—A critical discussion of methods of calcn. of energy requirements with special reference to the system and data of Armsby.

H. B. LEWIS

Cellular changes under vitamin insufficiency. II. Liver, spleen, kidneys, supra-renal gland. P. HENRIKSEN. *Norsk Magazin Laegevidenskab.* **86**, 540-5(1925); cf. *Ibid* 265.—Five guinea pigs and 8 rats were fed on oats and water for 19-27 days and were then given food contg. sufficient amts. of vitamin A, and after some time those still living were killed. In all the organs examd. an extensive degeneration of the cells was observed.

C. A. ROBAK

F—PHYSIOLOGY

ANDREW HUNTER

Action of uric acid on the cardiac activity of *Testudo graeca*. BOLDRINO BOLDRINI. *Arch. farm. sper.* **40**, 112-8(1925).—The isolated tortoise heart continues to function 6-12 hrs. in the presence of physiol. NaCl soln. After it has stopped beating, even for several hrs., it may be revived by treatment with an isotonic soln. contg. 0.244% K urate and 0.86% NaCl . The stimulating action of the urate is not due to variations in osmotic pressure. There is probably some connection between this stimulation and the fact that tortoise blood is rich in uric acid. The action appears to be of a hormone nature similar to that exerted by urea in other animals. Part of the uric acid is destroyed during contact with the isolated heart.

A. W. DOX

Constancy of metabolism under normal living conditions. MAX REISS AND ROBERT WEISS. *Klin. Wochschr.* **4**, 2207-8(1925).—Rats and mice that are allowed to select their food and that have adequate space for free movement show a const. metabolism (as detd. by O consumption) for a 24 hr. period, to within 5%.

MILTON HANKE

Sexual glands and metabolism. IV. Influence of injections of emulsions of testes and prostate and of insulin-like testicular extracts upon the nitrogen metabolism of normal, castrated and thyroidectomized rabbits. VLADIMIR KORÉNCHEVSKII AND

MARJORIE CARR. *Biochem. J.* **19**, 773-82(1925); cf. *C. A.* **20**, 65.—Testes emulsion and insulin-like substances obtained from the testis produced only a slight fall in the N metabolism of normal or castrated rabbits, whereas in thyroidectomized animals the decrease in N metabolism was much more marked. In thyroidectomized rabbits, an emulsion of prostate alone produced practically no change in the N metabolism, whereas an emulsion of both prostate and testis usually decreased the N metabolism, although to a less degree than when an emulsion of testis alone was injected. B. H.

Lactic acid in mammalian cardiac muscle. I. The stimulation maximum. L. N. KATZ AND C. N. H. LONG. *Proc. Roy. Soc. (London)* **99B**, 8-20(1925) —The heart is dependent on its contemporary O supply, and fails rapidly in the absence of that supply, while skeletal muscle is unaffected by short intervals of lack of O. The heart cannot go into "O debt" to anything like the extent of skeletal muscle. Expts on 20 cats and rabbits demonstrated that the stimulation max. is much less in the heart than in skeletal muscle, having a mean value of 0.072% lactic acid in the former and 0.252% lactic acid in the latter. The heart is deficient in buffering power, and, therefore, is more susceptible to the accumulation of H ions. **II. The rigor mortis maximum and the normal glycogen content.** H. J. G. HINES, L. N. KATZ AND C. N. H. LONG. *Ibid* 20-6.—The rigor mortis max. and the caffeine rigor max. of lactic acid in cats is one-half as great in the heart as in the skeletal muscle. In normal well-fed animals, the glycogen content of the heart is much smaller than that of skeletal muscle. The heart shows a greater discrepancy between the resting glycogen content and the lactic acid produced in rigor mortis, than does skeletal muscle. Lack of a precursor of lactic acid is not the cause of the relatively low stimulation max. of that acid in the heart; however the major portion of this precursor is not glycogen, but may be a hexose phosphate or some related compd. **III. Changes in hydrogen-ion concentration.** L. N. KATZ, PHYLLIS T. KERRIDGE AND C. N. H. LONG. *Ibid* 26-7.—After stimulation to fatigue, skeletal muscle is more acid than cardiac muscle by approx. 0.2 p_H . In rigor mortis, skeletal muscle is more acid than cardiac muscle by approx. 0.4 p_H . The ratio of the concn. of lactic acid added to the resulting change in p_H varies with the type of muscle and with the p_H . It attains its max. at approx. p_H 6.3; here the ratio of the buffering power of skeletal muscle to that of cardiac muscle is approx. 2:1. In rigor mortis, apparently lactic acid is the only acid formed in the muscles. JOSEPH S. HEPBURN

Mechanism of muscular contraction. W. E. GARNER. *Proc. Roy. Soc. (London)* **99B**, 40-56(1925); cf. *C. A.* **19**, 2694.—The tension generated on application of a stimulus to a muscle fiber is due to the formation of a solid film on the surfaces of the ultimate fibrils. The anisotropic segments of muscle contain liquid crystals composed of long-chain C compds. The mols. of these compds. are so orientated that their chains are parallel to the axis of the fiber. A solid film is produced on the surface of the anisotropic segments by the action of lactic acid. Glycogen is converted into K lactate by a series of reversible reactions, the direction of which is influenced by changes in the surface energy of the membranes during movement of the muscle. If all the energy liberated during conversion of glycogen into lactic acid is not utilized in doing external work a portion may be stored by reversal of the series of reactions. J. S. H.

Effects of calcium and potassium ions on urine secretion as studied in the whole animal. I. BRULL AND F. EICHHOLTZ. *Proc. Roy. Soc. (London)* **99B**, 57-70(1925).—In the intact anesthetized dog, intravenous administration of KCl increases the flow of urine to a much greater extent than similar administration of a corresponding amt. of NaCl. This increase is not due to hydremia or changes in blood pressure. The excretion of chlorides is not constantly or specifically influenced by either KCl or CaCl₂ or a combination of the 2 salts. After removal of the pituitary, K or K plus Ca increases the flow of urine, Ca has no effect, and NaCl has but a slight effect. Ca plus K (actually Ca working on a background of K) increases the chloride content of the urine up to that of the serum. JOSEPH S. HEPBURN

Hydrolysis of phosphoric esters by the kidney in vivo. F. EICHHOLTZ, ROBERT ROBISON AND I. BRULL. *Proc. Roy. Soc. (London)* **99B**, 91-106(1925).—When an isolated kidney is perfused with a heart-lung prepn., it is unable to conc. the normal inorg. phosphate of the blood serum, but is able to conc. and hydrolyze added org. phosphates, and to excrete their P as inorg. phosphates in the urine at a much higher concn. than that of the inorg. phosphates of the serum. In the whole animal, in which the inorg. phosphates of the urine have decreased to a min. after removal of the pituitary or puncture of the tuber cinereum, injected org. phosphates are excreted, after an initial stage, entirely as inorg. phosphates. The suggestion is made that, normally, a considerable part, if not all, of the urinary phosphates are derived from the org. phosphates of the serum by enzymic hydrolysis in the cells of the kidney. JOSEPH S. HEPBURN

Glyconeogenesis. J. MARKOWITZ. *Am. J. Physiol.* **74**, 22-35(1925).—Adrenaline hyperglucemia can be evoked only in presence of glycogen in the liver. In rabbits made completely glycogen-free by starvation, strychnine injections and cold adrenaline caused deposition of glycogen in liver, heart and muscles, but no hyperglucemia. Simultaneous treatment with adrenaline and insulin is followed by an accumulation of glycogen in the liver up to 2.77%. This and other evidence quoted from the literature suggest that glycogen is an obligatory step in the formation of blood sugar from non-carbohydrate stores (fat). It is possible that fat is oxidized not as such but as glucose. In this case the low respiratory quotient of fat oxidation may be due to a decrease in the phase of transformation.

MARY JACOBSEN

Observations on depancreatized dogs before and after the withdrawal of insulin. I. L. CHAIKOFF, J. J. R. MACLEOD, J. MARKOWITZ AND W. W. SIMPSON. *Am. J. Physiol.* **74**, 36-48(1925).—The percentage of sugar and ketone bodies after the withdrawal of insulin was decidedly higher in fat dogs than in lean ones, but there was no constant difference in the amt. of fat or P. Acetoacetic acid was relatively high in fat dogs; hydroxybutyric acid was high in thin dogs. Fat animals died much sooner after the withdrawal of insulin under symptoms similar to those of diabetic coma. After the discontinuation of insulin and food the glucose/N ratio declined far below 2.8. After readministration of insulin sugar, inorg. P and hydroxybutyric acid diminished at uniform rates, acetoacetic acid fell more slowly, fat not at all. The P rose first after the insulin effect has passed off. In one of 3 animals the excreted glucose was higher than the ingested. The marked difference between fat and lean dogs is suggestive of a relationship between fat and sugar.

MARY JACOBSEN

Studies on the physiology of the liver. XI. The extrahepatic formation of bilirubin. F. C. MANN, J. L. BOLLMANN AND C. H. SHEARD. *Am. J. Physiol.* **74**, 49-60(1925); cf. *C. A.* **20**, 437. Spectrophotographical curves of the same general appearance were obtained from: (1) the yellow pigment isolated from the fat, plasma and urine of completely hepatectomized dogs, which gives all the chem. tests of bilirubin, (2) bilirubin obtained from the liver of the animals at the time of liver extirpation, (3) the pigment isolated from the plasma of a dog with the common bile duct obstructed and gall bladder excised. The identity of (1) with bilirubin and its extrahepatic formation are thus established.

MARY JACOBSEN

The chemical sensitiveness of the kidneys. E. F. ADOLPH. *Am. J. Physiol.* **74**, 93-110(1925); cf. *C. A.* **17**, 2133. An apparent constant threshold value exists under specified conditions for the excretion of urea, acids, NH_3 and creatinine in man, dog and rabbit. With high water intake and excretion a slightly different type results. When the threshold value is included, a constant excretory ratio is always found between the concentration of the substance in the blood and the rate of its excretion. The excretory ratio has the same value for urea and phosphates and possibly also for other substances so that a similar excretory mechanism may be inferred. Under ordinary conditions substances are often carried through the kidneys by a passive process in addition to the actively secreted.

MARY JACOBSEN

Notes on the relationship between volume and reaction of urine specimens. R. S. HUBBARD. *Am. J. Physiol.* **74**, 111-4(1925); cf. *C. A.* **18**, 2371. In general no relationship was found between the vols. and reactions of urine specimens excreted in 1 hr. Very small vols. usually coincided with acid reaction, but in a no. of instances this was not the case.

MARY JACOBSEN

Studies of emotional reactions. IV. Metabolic rate. CARNEY LANDIS. *Am. J. Physiol.* **74**, 188-203(1925).—It is concluded from a review of the literature that altered emotional conditions in psychotic patients do not necessarily affect the metabolic rate. L.'s expts. have shown that elec. stimulation alone or in conjunction with a gastric balloon, anticipation of strong elec. stimulation or anger cause either an increase or a decrease of metabolic rate of largely varying magnitude. Prolonged insomnia and fast had no effect at all. The variations are partly due to muscular activity but chiefly to vascular changes involving the vol. flow of blood.

MARY JACOBSEN

Heat regulation and water exchange. X. Water, salt and lipid accumulation in the serum as a preliminary to sweating. H. G. HARBOUR, M. H. DAWSON AND I. NEUWIRTH. *Am. J. Physiol.* **74**, 204-23(1925); cf. *C. A.* **18**, 1141. In hot environments water, salts and lipids are mobilized into the serum. The increase in the serum and the decrease in the whole blood of the ratio sp. gr./solids suggest that the salts migrate from the blood cells. Hydremia is maintained until the sweating is severe enough to induce anhydremia. The salt level is also maintained high, while the lipids decline as the sweating progresses. The increase of O satn. in the peripheral blood is believed to be responsible for hydremia and sweat production.

MARY JACOBSEN

Relative rates of secretion of various milk constituents. W. L. GAINES. *J. Dairy Sci.* **8**, 486-96(1925).—A statistical analysis of results of chem. analysis of 543 samples of cow milk (Haecker, *C. A.* **8**, 1979) is made use of for a physiol. interpretation of the relative ratio of secretion of various constituents of the milk at a constant level of activity of the mammary gland. Secretion of fat and protein seems to be intimately related, $p = (1.46 \pm 0.40 f) \pm 0.19$. This relation appears to hold very closely also between several species, covering a range of fat % from 0.36 to 22.46. The secretions of H_2O and fat or protein are largely independent.

A parathyroid hormone and its physiological action. J. B. COLLIP. *Ann. Clin. Med.* **4**, 219-30(1925); cf. *C. A.* **20**, 622.—Parathyroid tetany in dogs could be prevented or controlled by the subcutaneous administration of parathyroid hormone, and the blood serum could thus be kept within normal limits. Its administration to normal dogs caused an increase in serum Ca. Repeated injections at short intervals caused death. Just before death the blood Ca, P and non-protein N went up, the viscosity increased, and blood vol. decreased.

H. B. LEWIS

JOHN T. MYERS

G—PATHOLOGY

H. GIDEON WELLS

The value of the Fornet tuberculosis diagnosticum and its composition. G. BIGNAMI. *Z. Tuberk.* **41**, 191-7(1924).—The Fornet tuberculosis diagnosticum test was found not to be one of agglutination but rather a precipitation test dependent upon the content of the serum in albumin and globulin and their relation to each other. As a result of tests with other chem. mixts. it was found that the Fornet diagnosticum is a 0.6% carbolic acid soln. of Na phosphate contg. a sparse amt. of the acid constituents of the bacilli, and that the reaction is dependent not upon the bacillary content but rather upon the acidity. The Na phosphate ppts. certain of the serum protein fractions. The reaction is non-specific and of a non-immune nature and is of no diagnostic value in tuberculosis.

H. J. CORPER

Favism. C. LOTTI AND A. MANAI. *Sperimentale* **79**, 791-846(1925).—From the *fave* (a species of bean), as well as the kidney bean, exts. are easily obtained which, injected intravenously, cause death after hemoglobinuria, or if recovery follows, cause the subsequent appearance of bile pigments and urobilin in the urine. *In vitro* the exts. strongly agglutinate red cells, indicating the hemoglobinuria is due to colloidoclastic shock. Press juice from *fave* flowers (I) caused excitability, and, in large doses, death in a few min. with generalized convulsions. Both types of action occur in the juices of the green beans (II) while ext. of dried beans (III) usually causes only the former. Rabbits prepared with I react specifically with anaphylactic shock to I, II and III, as well as to ext. of dried kidney beans (IV); in animals surviving the convulsions, hemoglobinuria ensues. III and IV do not sensitize to I and II. The hemolytic property of the protein is destroyed by heat, but not the sensitizing power. II sensitizes to I and II almost as well as does I, but subsequent injections of III and IV usually cause only hemoglobinuria, just as they do in animals prepared with III and IV. Thus the effects of the colloidoclastic shock and anaphylactic shock may be distinguished, even in many cases in which they occur together. The anaphylactic state may be passively transmitted, even from hypersensitive humans, to the rabbit. The applications of the findings to clinical observations are discussed. A table is given of the density, surface tension, protein, total N and N in lethal dose of each ext.

M. HEIDELBERGER

Behavior of the sera of various animals in the colloidal benzoin reaction. G. ROY. *Sperimentale* **79**, 885-94(1925).—Each species of animal tested (ox, sheep, pig, guinea pig, rabbit, cat) gave a curve characteristic in the positions of the zones of flocculation.

M. HEIDELBERGER

Ovarian function, potassium and calcium content of the blood serum and the vegetative system. G. K. F. SCHULTZE. *Arch. Gynakol.* **126**, 35-44(1925).—The normal K:Ca ratio in the blood is 2:1. The Ca content seems to be more stable than the K content, and the normal value varies from 9.5 to 10.5 mg. per 100 cc. The K content may be as low as 14 mg. per 100 cc., particularly in the amenorrhea of young girls. There are certain relations between the ovarian function and the K and Ca content of the blood that indicate an influence of the corpus luteum on the sympathetic system. When the influence of the corpus luteum is lacking, as in the amenorrhea of young girls, there may be a heightened activity of the vagus, with an alteration of the ratio of K to Ca.

HARRIET F. HOLMES

Physiology of water metabolism in pregnancy. H. RUNGE AND R. KESSLER. *Arch. Gynakol.* **126**, 45-64(1925).—Measurements were made of the oncotic (osmotic)

pressure of the plasma colloids in pregnancy and the puerperium by the use of the Schade and Claussen method. Detns. were made also of the concn. of plasma proteins, viscosity of the plasma, residual N, and rapidity of sedimentation of the blood corpuscles. The oncotic pressure of the plasma colloids rises in the beginning of pregnancy, becomes lower after the fourth month, rises suddenly during labor, and falls in the first days after delivery. The changes in protein concn. of the plasma run parallel to some extent. The specific viscosity varies in the opposite sense to the specific oncotic pressure.

HARRIET F. HOLMES

The action of iodine-thyroglobulin on diuresis and metabolism in pregnant women. A. MAHNERT. *Arch. Gynakol.* **126**, 125-43(1925).—Intravenous injection of iodine-thyroglobulin in pregnant women caused a marked increased excretion of uric acid, urea and NaCl, with or without diuresis. Diuresis was more apt to follow in cases with edema. The cholesterol content of the blood was lowered. H F H

Obstruction of the renal tubules during the excretion of hemoglobin. S L BAKER AND E. C DODDS. *Brit J Exptl. Pathol* **6**, 247 60(1925) —*In vitro* expts. indicate that hemoglobin is thrown out of soln. when the reaction of the medium is not more than about pH 6 and the NaCl content is about 1% or over. Rabbits on an ordinary diet and passing an alk. urine are unaffected by hemoglobin injections, but if the urine is kept acid by means of a suitable diet an intra-renal obstruction can be produced. It is probable that hemoglobin is excreted in soln. in the glomerular transudate. After concn. in the tubules the acidity and NaCl concn. increase, with the result that the pigment is pptd., probably in the form of hematin. This theory would explain the production of intra-renal obstruction in cases of the type described and in blackwater fever. A suggestion for the treatment of these conditions, based on the above conclusions, is offered, namely, the production of alk. diuresis.

HARRIET F. HOLMES

Etiology of dental caries. IV. Accessory factors in dental caries. (1) Reaction of the saliva. (2) Acid resistance of teeth. (3) Bacteriotropic action of saliva. J. MCINTOSH, W. W JAMES AND P. LAZARUS-BARLOW. *Brit. J Exptl. Pathol.* **6**, 260-6 (1925).—Saliva appears to be intimately connected with the occurrence or non-occurrence of dental caries, being more acid in those subject to the condition than in those who are immune. Experiments devised to show that teeth vary in their powers of resisting acid were inconclusive. The saliva may contain agglutinins against *B. acidophilus odontolyticus*, but only in small quantities. Saliva has no appreciable bactericidal action against *B. acidophilus odontolyticus*. **V. The chemical composition of saliva.** E. C DODDS. *Ibid* 266-8. —The nitrogenous constituents and the chlorides were detd. in saliva and blood by a modification of the method of Folin and Wu. The urea content of the saliva is very low and there is a large amt. of NH_4 . Saliva contains no sugar. The values found for saliva are much lower than those for blood and there seems to be no const. relationship between the constituents of the blood and saliva. The variations in the saliva are so wide that no clinical significance can be placed upon the figures at least for normal individuals.

HARRIET F. HOLMES

The influence of asphyxia on the motor function of the large intestine. H. S. LURJE. *Z. ges. exptl. Med.* **46**, 425-8(1925) —In asphyxia the contractions of the large intestine are increased, particularly when cyanosis of the intestine sets in. This increase in contraction in asphyxia is doubtless due to the action on the neuro-muscular apparatus of the wall of the intestine of blood of altered compn., with an increase of CO_2 and a decrease of O.

HARRIET F. HOLMES

The action of thyroxin on the human organism. I. The influence of respiratory metabolism by thyroxin. H. LÖHR AND W. FREYDANK. *Z. ges. exptl. Med.* **46**, 429-42 (1925). —Synthetic thyroxin (Squibb), on intravenous or intramuscular injection, greatly increases O metabolism. The body temp. may or may not be raised, but the increased oxidation bears no relation to changes of body temp. There is no effect on blood pressure or activity of the heart. In myxedematous patients thyroxin is especially effective and increases oxidation with a rapidity not seen after the use of any thyroid prepn. Small doses can bring O metabolism to normal, with an improvement in the symptoms of myxedema.

HARRIET F. HOLMES

Changes in hydrogen ion concentration in the living organism. N. HENNING. *Z. ges. exptl. Med.* **46**, 459-65(1925).—By the method of Gräff (cf. *C. A.* **18**, 3069) the pH values for the organs of the white mouse were found to lie between 7.0-7.3. It was not found possible to alter these values by intravenous injections of sublethal-doses of HCl or NaOH. Lethal doses of HCl or NaOH led to increased acidity or alkalinity in all organs except the brain. HCl injected directly into the muscles is neutralized in 2-3 hours and injected into the peritoneum is neutralized in 20 minutes. Distilled H_2O and physiologic NaCl injected into the peritoneum in a few minutes have

p_H value of 7.6-7.8, the p_H value of the blood serum in the mouse indicating that these fluids are made alkaline from the blood system, before or while resorption takes place.

HARRIET F. HOLMES

Surface tension. I. The daily course of surface tension in the urine in pathological conditions (with exclusion of diseases of the liver). D. ADLERSBERG AND M. SUGAR. *Z. ges. expil. Med.* **46**, 466-85(1925).—The surface tension of the urine was detd. at 3-hr. intervals in 30 pathological conditions and compared with the findings in normal persons. Normal cases show great variations in sp. gr. and surface tension of the urine in the course of the day. In early carcinoma and early tuberculosis there is little variation from the normal. In advanced cases of carcinoma or tuberculosis there is much less variation in the surface tension and the surface tension seems independent of the sp. gr. Similar relations were noted in blood diseases and Basedow's disease. In Basedow's disease there was found the greatest abs. amt. of substances affecting surface tension. **II. Surface tension of serum in normal and pathological conditions.** D. ADLERSBERG AND E. SINGER. *Ibid* 500-17.—The surface tension of the blood serum in normal persons varies from 875 to 889, rising slightly after meals. In blood diseases high surface tension was found. The surface tension is markedly lowered in liver disease, chronic nephritis, acute rheumatism and severe cases of diabetes. In chronic nephritis the lowering of surface tension seemed to run parallel with the severity of the disease, and the detn. of surface tension might be of diagnostic importance in this condition. **III. Surface tension and the true acidity of the stomach.** D. ADLERSBERG AND A. L. MOLNAR. *Ibid* 718-30.—That there is some relation between the true acidity of the stomach content and its surface tension is shown in that with the highest acidity values ($p_H = 1.1$ and < 1.1) the highest surface-tension values occur. On the other hand the surface tension may remain practically the same with lower degrees of acidity ($p_H = 1.3$ to 2.1). Administration of fat or protein leads to a marked diminution of surface tension which does not seem to be in direct relation to the usual diminution of the true acidity.

HARRIET F. HOLMES

Basal metabolism in nephritis. R. DÜRR. *Z. ges. expil. Med.* **46**, 573-93(1925).—Repeated detns. of basal metabolism in 15 cases of nephritis indicate that in general in acute stages of glomerulo-nephritis there is a rise in basic metabolism up to 133%, soon falling in the subacute stage to low normal or subnormal values. Chronic nephritis shows a basal metabolism mostly normal, though often low normal and occasionally subnormal. Acidosis seems to lower the basal metabolism. There is often a high preagonal rise in basic metabolism.

HARRIET F. HOLMES

Pathogenesis of bronchial asthma. III. Uric acid metabolism. K. HAJOS AND L. KÜRTI. *Z. ges. expil. Med.* **46**, 625-32(1925).—Asthma patients as compared with normal individuals show a marked delay in the excretion of exogenous uric acid. Pilocarpine causes in asthmatics an even greater delay in uric acid secretion or a total retention (parasympathetic action). Adrenaline increases the rate of uric acid secretion (sympathetic stimulus). The retention of uric acid is not to be considered as the cause of the asthma but as a result of the changed reaction of the asthmatic organisms to different stimuli.

HARRIET F. HOLMES

The urine of the last hours of life. J. MANTZ. *Z. ges. expil. Med.* **46**, 646-9(1925).—Urine taken after death showed in 36 of 37 cases a Cl concn. much less than that of the blood serum while the uric acid and N concns. were slightly above those of the blood serum.

HARRIET F. HOLMES

Experimental alimentary hypercholesterolemia in rabbits. N. A. SSKOLOFF. *Z. ges. expil. Med.* **46**, 650-5(1925).—The feeding of rabbits with egg yolk or cholesterol dissolved in oil causes a marked increase in the cholesterol content of the blood. If the feeding of cholesterol is continued for some time the resulting cholesterolemia persists for a long time after the feeding is ended. Feeding of milk, lanolin or oil from some lower acids caused little or no hypercholesterolemia.

HARRIET F. HOLMES

The influence of some substances that affect the parasympathetic system on the formation of antibodies (agglutinins). S. LITARCZEK. *Z. ges. expil. Med.* **46**, 656-65(1925).—Rabbits immunized with typhoid bacilli show an increased agglutinin titer after the intravenous injection of pilocarpine or physostigmine. This indicates that substances that are stimulants for the parasympathetic system exert a stimulating effect on the formation of antibodies.

HARRIET F. HOLMES

The meaning of hypercholesterolemia for the development of solitary xanthomatic granulomas. O. WUSTMANN. *Z. ges. expil. Med.* **46**, 731-9(1925).—Periosteal foreign-body granulomas with a high lipid content were obtained in rabbits following the injection of infusorial earth, only when a high cholesterolemia was present from previous cholesterol feeding.

HARRIET F. HOLMES

The adaptability of diseased kidneys to an acid or basic diet. H. LUCKE. *Z. ges. expil. Med.* **46**, 740-51(1925).—The p_H content of the urine was detd. during 3 days of a basic diet followed by 3 days of an acid diet in a number of cases of nephritis and in normal individuals. The adjustment to the change in reaction of the diet was much more delayed in the case of nephritis. In some cases of nephritis there was no change in the reaction of the urine on changes of diet and this occurred both with acid and neutral urines.

HARRIET F. HOLMES

Coagulation of the blood in the rabbit after the introduction of various substances. PL. BATTAGLIA. *Z. ges. expil. Med.* **46**, 752-9(1925).—The fibrin enzyme and fibrinogen content of the blood of rabbits were detd. before and after aleucocytosis had been produced by injection of benzene. It was concluded that the fibrinogen was not a product of the leucocytes, but that they contain an activator for the fibrin enzyme. Injections of various bacteria and proteins also indicated no mutual relations between leucocytosis or leucopenia on the one hand and fibrinogen and fibrin enzyme on the other.

HARRIET F. HOLMES

The meaning of the acetone bodies for the organism and the occurrence of diabetic coma. K. HARPUDER AND H. ERBSEN. *Z. ges. expil. Med.* **46**, 768-83(1925).— β -Hydroxybutyric acid inhibits the action of a number of enzymes and also cell respiration and reduces the stability of various proteins. This action of β -hydroxybutyric acid is similar to that of a narcotic poison and is independent of its acid nature. A similar action of acetoacetic acid was not made out clearly. In diabetic coma there is frequently a concn. of β -hydroxybutyric acid sufficient to cause a disturbance of metabolism and independent of its acid nature.

HARRIET F. HOLMES

Is the reaction of a tuberculous person to "Tebeprotein" to be considered as a protein anaphylaxis? E. TRENNIESSEN. *Z. ges. expil. Med.* **46**, 789-98(1925).—"Tebeprotein" is a protein isolated by the author some years ago from tubercle bacilli by slight hydrolytic splitting of the protein of the tubercle bacillus. On injection of Tebeprotein a rapid rise of temp. and reddening at the site of injection are diagnostic of tuberculosis. This Tebeprotein reaction is not an anaphylaxis and the Tebeprotein is not an anaphylactogen nor a precipitinogen. The specific reaction is not to be explained as an antigen-antibody reaction as is the anaphylactic reaction against native tubercle bacilli protein, but probably depends on a heightened specific irritability of the cells.

HARRIET F. HOLMES

A new investigation of the Wassermann reaction. RICARDO CALATRONI. *Rev. Facultad Ciencias* **3**, No. 2, 125-9(1925).—In 1918 Scaltriti introduced a new antigen consisting of the freshly extd. phosphatides of hog heart in the form of their Cd salts. Noguchi's ether extn. was found by S. to increase the antialexin properties of the antigen and to make the lecithins partly insol. By direct extn. of the tissue first with acetone then with abs. alc. and pptn. of the alc. ext. with $CdCl_2$, C. has replaced the unstable alc. emulsion of S. by a nonhygroscopic, white sol. powder, which retains its original activity for at least 8 months. The phosphatides of leguminous plant seeds have the same effect in the Wassermann reaction. Both antigens were free from hemolytic or anticomplement properties and gave in 94% of the cases the same results as the common antigens.

MARY JACOBSEN

Researches on blood sugar in Indians. I. Blood sugar observations in young people in Bengal. UPENDRA NATH BRAHMACHARI AND PARIMAN BIKASH SEN. *Indian J. Med. Research* **13**, 271-4(1925).—"Defective sugar tolerance is manifested among many medical students in Bengal living on a dietary contg. a large amt. of carbohydrates. These are potential diabetics."

FRANCES KRASNOW

Simultaneous respiratory exchange and blood sugar time curves obtained in diabetic and non-diabetic individuals following ingestion of glucose. I. M. RABINOWITZ, with assistance of A. B. FRITH AND E. V. BAZIN. *J. Clin. Invest.* **2**, 143-56(1925).—By means of such studies the authors suggest a distinction between two forms of diabetes mellitus—one in which there is defective storage of carbohydrates, and in the other defective oxidation. The former type seems to be present in the more severe cases. In renal glucosuria (5 cases) and in pituitary disease with glucosuria (2 cases), normal values were obtained.

LOUIS LEITER

Total acid-base equilibrium of plasma in health and disease. VI. Studies of diabetes. J. P. PETERS, H. A. BULGER, A. J. EISENMAN AND C. LEE. *J. Clin. Invest.* **2**, 167-211(1925).—An analysis of 53 cases of diabetes of varying severity is presented. Ketosis has a variable effect on the total electrolytes of the serum. The total base may be normal, often low, rarely high. Bicarbonate is spared by reduction of chlorides in the serum and consequent liberation of base combined with the latter. In acute ketosis both serum bicarbonate and chlorides are reduced. In this manner there is less dis-

turbance of p_H by the organic acids in severe acidosis. The chloride ion may pass very rapidly into the tissues, liberating its base in the serum. In very severe instances the chloride content of the body is also probably depleted by actual excretion (as NH_4Cl). Loss of salt or base leads to dehydration; primary loss of water (due to glucosuria) will lead to loss of salt. These two forces operate together in diabetic toxemia. The administration of NaCl in such cases is advised in view of its sparing action on bicarbonate and the respiratory mechanism.

LOUIS LEITER

Tissue oxygen tension with special reference to tetany and convulsions. J. A. CAMPBELL. *J. Physiol.* 60, 347-64(1925).—Air injected under the skin and allowed to remain until equil. of O_2 and CO_2 tensions with the blood and tissues is established shows a rise in O_2 content when convulsions or tetany occur. Tetany was produced in various ways, such as by KCN, strychnine, parathyroidectomy and by the intravenous injection of NH_4Cl , $CaCl_2$, $SrCl_2$ and NaCl. The main factor causing the rise of O_2 tension under the skin following tetany seems to be acidosis and the resulting increased liberation of O_2 from oxyhemoglobin. It is suggested that tetany and convulsions are caused by O_2 deficiency in the brain cells and that the purpose of tetany is to counteract this defect.

J. F. LYMAN

Calcium in the blood of pulmonary tuberculosis. AXEL LOOFT. *Compt. rend. soc. biol.* 91, 190-1(1924); cf. *C. A.* 18, 553.—In light cases the Ca content of the blood was 0.099-0.107 g./l., while in 5 advanced cases it was 0.09-0.105; there was therefore no evidence of any diminution of the Ca content of the blood in tuberculosis. W. B. P.

Content of growing tissue in cozymase and inhibitory substance. I. HANS V. EULER AND KARL MYRBÄCK. *Arch. ges. Physiol.* (Pflüger's) 210, 521-6(1925).—In 2 cases of carcinoma of the breast an increase in cozymase was observed in the surrounding normal tissue, and at the same time the inhibitory substance was slightly augmented. In one case of carcinoma of the liver more inhibitory substance was found within the surrounding tissue than in the carcinomatous tissue. G. H. S.

Spasmophilia. H. VOLLMER AND J. SEREBRIJSKI. *Z. Kinderheilk.* 39, 655-64(1925).—In normal healthy infants the administration of chloral hydrate causes but very slight changes in the Ca and K, the av. values showing a slight reduction. P is unchanged. In spasmophilic infants, on the contrary, chloral hydrate administration causes an increased Ca, a uniform reduction in K, and no change in P. Infants showing clamtptic convulsions invariably show a reduction in the serum Ca of from 5.5 to 8 mg. %.

ALFRED N. RICHARDS

Acid therapy: Its origin, scientific fermentation and practical application. Dry acid vapors as prophylactic and curative agents. PAUL HASSACK. *Fruit Products J. and Am. Vinegar Ind.* 5, No. 4, 15-6(1925).

J. A. KENNEDY

The quantitative distribution of veronal in the organs in a case of veronal poisoning. G. W. PUCHER. Buffalo General Hospital, *Bull.* 3, 70-1(1925).—The detn. of the veronal content of the urine, and the organs was made according to the method of van Itallie and Steenhauer (*C. A.* 15, 2893) with several modifications. The results confirm the observation of other investigators that most of the veronal is to be found in the urine. The organs contain, however, appreciable quantities, particularly the liver, kidneys, brain and spleen. Calcd. on the basis of veronal per 100 g. of tissue it was found that the kidney is the highest and the brain next in veronal content. NATHAN VAN PATTEN

12—FOODS

W. D. BIGELOW AND A. E. STEVENSON

The loss of mineral and other constituents from vegetables by various methods of cooking. W. H. PETERSON AND C. A. HOPPERT. *J. Home Econ.* 17, 265-80(1925).—The losses of solids, crude protein, Ca, Mg, P and Fe by 4 methods of cooking, namely, steaming, pressure cooking, boiling with moderate amt. of H_2O , boiling with double quantity of H_2O , in general all increased with the methods in the order named, the % loss ranging from zero for Ca in steamed spinach to 76% for Mg in boiled cabbage. The approx. av. losses for solids and crude protein were 15% by steaming and pressure cooking, 30% by boiling in a moderate amt. of H_2O , and 40% in double quantity. For Ca the losses were 10% for steam and pressure cooking and 20% and 30%, resp., for

the 2 boiling methods. Mg showed 20% loss for the first 2 methods and 30% and 45%, resp., for the 2 boiling methods. The av. losses for P and Fe were the same as those for Mg except in the case of the boiling procedures, where the figures are 5-10% higher. Cabbage, celery, beet greens and onions showed notably large losses, especially of minerals in the case of the last 3. Spinach retains all its Ca when cooked. L. D. F.

The estimation of pectin and a study of the constitution of pectin. C. F. AHMANN AND H. D. HOOKER. Missouri Agr. Expt. Sta., *Research Bull.* **77**, 5-39 (1925).—A method for estg. pectin by titration of the acidity developed on sapon. of pectin and the effect of time and temp. on the process is described. Under const. conditions the amt. of pectin found is proportional to the acidity developed. Titration curves of pectic acid show 11 carboxyl groups, but evidence is presented to show that sapon. was not complete, which would indicate that there are more than 11 carboxyl groups in pectic acid. On the basis of 12 carboxyl groups the mol. wt. of pectic acid would be 2124. The nucleus proposed for pectic acid is a dibasic acid galacturonic-galactonic acid. At least 6 of these nuclei are linked together to form pectic acid. Pectin dissolves in cond. HCl and undergoes hydrolysis and decompn. A method of sepg. the hydrolytic products produced by the cold concd. HCl is described and a preliminary study of some has been made. J. J. SKINNER

The evaluation of pectin raw material. WM. A. ROOKER. *Fruit Products J. and Am. Vinegar Ind.* **5**, No. 5, 22-5 (1926).—R. takes into consideration phys. appearance, moisture content, and the jelly test or detn. of the units of jelly strength. J. A. KENNEDY

Citrus and apple "pectins." R. O. BROOKS. *Fruit Products J. and Am. Vinegar Ind.* **5**, No. 4, 5-6 (1925). J. A. KENNEDY

Should flour be artificially bleached and matured? JAVILLIER. *Ann. fals.* **18**, 580-95 (1925).—From a detailed discussion of the various bleaching processes and the action of the bleaching agents on the constituents of wheat flour, J. concludes that: bleaching does not meet any physiological requirement of the consumer; it might allow of increasing the % of extn. and the nutritive value of the flour, at the same time meeting the present demand for very white flour; some advantage might be obtained from the maturing effects of bleaching and from the improved keeping qualities of the bleached flour, but these 2 points would require further study before a definite conclusion could be drawn; the main disadvantage is the destruction of vitamin A, and to a lesser extent the possible formation of toxic decompn. products, but the latter is not likely owing to the small amt. of bleaching agent used. Regulations limiting bleaching are suggested. A. PAPINEAU-COUTURE

Bread as the physician sees it. MORRIS FISHBEIN. *Am. Food J.* **20**, 474-7 (1925).—The author discusses the value of food in general and especially the value of bread, bread for reducing, and whole wheat. J. A. KENNEDY

Use of low temperatures in the preparation of pure proteins. T. R. PARSONS. *Proc. Fourth Intern. Congress of Refrigeration* **1**, 194 (1924).—By simultaneous freezing and centrifuging it was found possible to sep. an upper layer of ice and a lower layer of hemoglobin crystals. It is easier, though theoretically less efficient, to centrifuge during the thawing of the previously frozen soln. *Egg-white* treated by this process yields a thick layer of ice above a very viscid concd. soln. contg. crystals, which mixt., on short exposure to the air, dries to a yellowish, glassy mass which can be kept indefinitely without change. The method is suggested as being suitable for the com. dehydration and concn. of food materials. A. PAPINEAU-COUTURE

Some problems of the freezing of beef presented to a biochemist. D. L. FOSTER. *Proc. Fourth Intern. Congress of Refrigeration* **1**, 247-50 (1924); cf. Fearon and Foster, *C. A.* **17**, 315.—Method and rate of freezing have considerable effect on the autolysis of beef. In unfrozen beef, the sol.-N content on autolysis increased from about 10.5 to about 13% of the total N in 10 days and then remained const. In beef frozen in the ordinary way in air at -8° the sol. N increased from about 10.5 to 16% in 20 days; while in beef frozen by immersion in satd. brine at -8° the autolysis curve was strictly comparable to that of unfrozen beef. Absence of "drip" on thawing brine-frozen beef would indicate that by this method any extensive damage to the cell is avoided. The brown color produced to a depth of about 0.5 in. in brine-frozen beef was shown to be due to the formation of methemoglobin. Prevention of the discoloration was successfully carried out on a small scale by reduction of the oxyhemoglobin to hemoglobin previous to freezing; but it is doubtful if such a process could be successfully applied on a com. scale on beef quarters. Addn. of NH_3 to an ordinary NaCl brine also prevented discoloration, which was found to be due to formation of an alk. deriv. of methemoglobin. A. PAPINEAU-COUTURE

Freezing of eggs. T. MORAN. *Proc. Fourth Intern. Congress of Refrigeration* 1, 122-37(1924); cf. C. A. 20, 75.—When egg yolk is frozen at any temp. above -6° , on thawing it is apparently unchanged; if frozen below -6° the yolk changes to a pasty nonfluid condition. Egg yolk frozen in liquid air and thawed at room temp. is also irreversible, while if thawed rapidly it reverts to the fluid condition of fresh yolk. Eggs supercooled to any temp. above or below -6° do not suffer any apparent change. White of eggs on freezing and thawing becomes more fluid. The nature and possible theoretical explanation of these changes are discussed, and the state of our knowledge with regard to the general freezing of tissues is briefly outlined. Bibliography of 14 references.

A. PAPINEAU-COUTURE

Rendering soluble the organic constituents of milk. Its applications. R. VLADESCO. *Lait* 45, 479-83(1925).—*Detn. of fat:* As the outcome of an attempt to find a method for detg. fat in animal tissues, V. arrived at the following method for fat detn. in milk: add 20 cc. concd. HNO_3 to 10 cc. of milk and heat the mixt. in a 100-cc. Kjeldahl flask over a flame with continual agitation for 5 min. To the hot liquid add 10 cc. of water and cool the flask by plunging into cold water. To avoid congealing in a mass, shake the flask vigorously while cooling. This can be done under running water. When the fat is completely solidified, filter the liquid through a filter paper, previously tared, into a glass-stoppered flask. All the particles of fat can be brought onto the filter paper with several washings by cold water. Place the filter paper contg. the fat in the glass-stoppered flask, dry in the hot air drying oven, cool in a desiccator and weigh. The difference in the 2 weights gives the quantity of fat contained in 10 cc. of milk.

H. F. ZOLLER

The abnormal increase in the refractive index of calcium chloride serum from sour milk. L. PANCHAUD. *Lait* 5, 777-82(1925).—The unexpected increase in the n of CaCl_2 serum from sour milk is due principally to the formation of Ca lactate at the expense of the casein. The Ca lactate remains in soln. in the serum, raising the n , until all the Ca of the casein is satd. Once this is attained the n decreases, assumes once more the original value of the fresh milk, then again decreases. H. F. ZOLLER

Note on the determination of fat in powdered milk. A. SCHOONJANS. *Lait* 5, 782-5(1925).—The Röse-Gottlieb method of fat detn. is compared with the Weibull method. The latter gave slightly higher results and was found to be more accurate than the former. The Weibull method is in turn compared with the Teichert method, which is a recent modification of the butyrometric Gerber method. The Weibull and Teichert methods show very close agreement. The latter is recommended for simplicity, rapidity of operation and accuracy.

H. F. ZOLLER

Effect of a wound on the composition of cow milk. O. R. OVERMAN AND F. P. SANMANN. *Ann. faks.* 18, 531-2(1925).—As a result of an accident a cow developed a hernia which caused a swelling 15-20 cm. in diam. in front and to the right of the udder. Samples of her milk taken 5 and $2\frac{1}{2}$ weeks before the accident, and just after the accident, gave the following results: total solids 11.92, 11.55, 8.86; ash 0.77, 0.64, 0.67; fat (Röse-Gottlieb) 3.96, 4.00, 2.44; total proteins 3.56, 3.13, 3.15; lactose (polarimetrically) 3.77, 3.72, 2.50%; d. 1.0286, 1.0289, 1.0244, resp.

A. P.-C.

Determination of sucrose in condensed milk and in chocolate. GUNNER JØRGENSEN. *Ann. faks.* 18, 517-29(1925).—A detailed discussion of the subject and description of the results of J.'s investigations. Irregularities observed in the polarimetric readings of lactose solns. of identical concn. are shown to be due to variations in p_H , slight alky. (p_H 7.3) resulting in a considerable reduction in the reading. The slight pptn. of sugar by basic Pb acetate observed by German chemists was never observed by J., and is attributed by him to the fact that the Pb subacetate of the German Pharm. is much more basic than that of the Danish Pharm. When inverting sugar with HCl by immersing the soln. for 30 min. in a boiling water bath, inversion is not always complete with a p_H of 2.0, but is always complete with a p_H of 1.8-1.6, while with a p_H of about 1.0 there is partial decompn. of fructose. The proper acidity can be obtained, irrespective of the presence of buffers, by adding 4 drops of thymol blue (Clark's soln.), adding N HCl to a permanent red, and then 1 cc. in excess (for a final vol. of 100 cc.). The polarimetric reading of an inverted soln. of a mixt. of lactose and sucrose does not immediately assume its true value, and the soln. should be allowed to stand overnight before being read. In the detn. of fat in sweetened condensed milk, if the milk has been homogenized, or if the fat has been decomposed with liberation of fatty acids, it is preferable to use acids rather than NH_4OH as prescribed by Röse-Gottlieb. But if material contg. considerable sugars is heated with HCl, the sugars are partly decomposed with formation of Et_2O —and petrolic ether-sol. substances, which give high results. Accurate results can be obtained by allowing the mixt. of sample and acid to stand for

1-2 days in the cold and then extg. as usual. Using known quantities of sucrose and cocoa (fat content 50%) from the theoretical and observed polarization readings *J. calcd.* that the av. vol. of ppt. was 0.93 cc. per g. of cocoa as such, and 0.79 cc. per g. of fat-free cocoa.

A. PAPINEAU-COUTURE

Viscosity, surface tension, and whipping properties of milk and cream. A. C. DAHLBERG AND J. C. HENING. New York Agr. Expt. Sta., *Tech. Bull.* 113, 42 pp. (1924).—The viscosity of milk and cream increased with aging and with increased percentages of fat, but both effects were variable. The effect of fat was most noticeable when the percentage was 20 or above. Pasteurization slightly reduced the viscosity of milk and greatly reduced the viscosity of cream. The effect of aging on viscosity was inhibited to a large extent by pasteurization. The viscosity of cream could be greatly altered by the condition of the milk fat at the time the milk was sepd. If the fat was in a semi-solid condition at the time of sepg., the viscosity of cream from pasteurized milk was made to resemble raw cream, and cream from raw milk was made much thicker. If the milk was not allowed to cool and was sepd. immediately after milking or pasteurization, the resulting cream had a low viscosity comparable to normal pasteurized cream. The surface tension of milk and cream decreased with an increased fat content, and it usually decreased with aging. Pasteurization usually increased the surface tension and aging would not reduce it to normal. The whipping qualities of cream were improved by increased percentages of fat and aging. Pasteurization had a slightly detrimental effect. Good whipping cream gave a reduced vol. of whipped cream when compared to poor whipping cream. Well-whipped cream stored at cold temps. remained whipped permanently with little or no drainage from the cream. In a general way, increased viscosity and decreased surface tension were associated with good whipping qualities. The viscosity of normal cream could be altered to upset its relationship to cream whipping. Abnormally viscous cream whipped well, but not better than normal cream of the same fat content.

J. J. SKINNER

A contribution to the analysis of milk, condensed and desiccated milk. HARRY HURST. *Analyst* 50, 438-40(1925).—Dialyzed Fe is a suitable precipitant for fat and casein in the analysis of milk products. The addn. of 12 cc. of the Fe reagent (B. D. H.) to 10 cc. of milk or 20 cc. of dild. condensed milk yields a ppt. from which the fat can be extd. and weighed. The filtrate is suitable for the detn. of sugars (Maclean's method) as well as for boric acid, benzoic acid, etc.

W. T. H.

Evaporated milk. H. C. HOOKS. *Am. Food J.* 20, 488-91(1925).—H. discusses the invention of evapd. milk, tests on arrival, evapn., process of homogenizing, sterilization, production, and uses and value as a baby food. There is an illustration to show what happens in the vacuum pan in mfg. evapd. milk.

J. A. KENNEDY

Air made toxic by cheese. A. J. PARKER. *Analyst* 50, 446(1925).—While inspecting the hold of a steamer, an official was rescued with difficulty in a state of cyanosis. Examn. showed that the CO₂ content of the hold was very high. Often when new cheese is placed in cold storage the atm. becomes nonrespirable because of CO₂ developed.

W. T. H.

Proposed weight standard for ice cream. W. W. SKINNER. *Am. Food J.* 20, 511(1925).

J. A. KENNEDY

Modification of the sesame oil reaction by treatment of the oil with adsorbents. P. HONG. *Chem. Weekblad* 22, 509-12(1925); cf. *C. A.* 18, 718.—The acid or alk. reaction of the decolorizing carbon or bleaching earth used for the bleaching of the oil affects the intensity of the Baudouin test. Acid adsorbents decompose sesamin and split off sesamol; the latter produces the color reaction. The steam distillate of oils so treated gives an intense Baudouin test. The best bleaching effects are obtained with slightly alk. or neutral adsorbents. Sesamin is adsorbed by bleaching earths as well as by decolorizing carbons. The treated oil, however, retains part of its optical activity because of another, nonadsorbable constituent. Oxidizing agents also interfere with the test.

MARY JACOBSEN

The micrococci associated with dairy utensils. A. H. ROBERTSON. New York Agr. Expt. Sta., *Tech. Bull.* 112, 3-18(1925).—Certain species of micrococci are commonly associated with machines where the tubes and teat-cups receive some form of chem. treatment to prevent bacterial growth between milking periods. The chemicals in the consns. used for sterilizing the tubes and teat-cups of milking machines appear to permit the reproduction of certain species of the micrococci and at the same time inhibit the growth of the non-spore-forming rods which are more commonly found on utensils. Data are given on the survival of the cultures. Of 11 species found, *M. candidus*, *M. freudenreichii*, *M. casei* and *M. conglomeratus* were sufficiently common to be

considered a part of the normal flora present in the tubes of milking machines.

The examination of food and condiments at frontiers. P. J. VAN HAMEL ROOS. *Chem.-Zig.* 49, 965(1925).—R. advocates (1) labs. at importing points, (2) examn. of imported foods, thereby obviating further analyses in cities, (3) return of rejected shipments at shipper's cost, (4) certification of food exports, (5) mutual regulations between countries available to exporters.

About curry. J. W. ADAN. *Pharm. J.* 115, 350-2, 366(1925).—A discourse on the literature, compn. and modes of use of this East Indian condiment. S. WALDBOTT

Contributions to the consideration of table mustards. J. L. WILLS. *Fruit Products J. and Am. Vinegar Ind.* 4, No. 9, 21-2; No. 11, 18-20; 5, No. 2, 19(1925).—Wills gives the results of the analyses of 40 commercially prepd. table mustards, compn. of test samples used, and the analytical methods employed.

Sauerkraut. J. J. O'BRIEN and ROY IRONS. *Am. Food J.* 20, 543-4(1925).—The authors describe chiefly the curing process.

Mucic acid for food purposes. L. WEIL. *Ann. fals.* 18, 529-31(1925).—A sample of American origin consists of 48% oxalic acid and 52% mucic acid. A. P.-C.

Preparation and contamination of sirups. C. E. MCKELVEY. *Am. Food J.* 21, 39-41(1926).

Candying of fresh figs. ALEXANDER MATHIEW. *Fruit Products J. and Am. Vinegar Ind.* 5, No. 2, 16-8; No. 3, 18-20; No. 4, 18-20(1925).—Mathew discusses present practices; essential points governing the quality of the candied product; the effect of heat; the effect of sirup concn.; rapid candying of figs under vacuum; cold storage fruit; chem. preservation; canned figs; preliminary treatment of fresh figs; comparison of sugar mixts.; open kettle concn.; plumping in final sirup; washing; drying; glacéing; and packaging.

Hard rubber equipment most suitable for handling food products containing acids. P. B. L'HOMMEDIEU. *Fruit Products J. and Am. Vinegar Ind.* 5, No. 5, 26-7(1926).

J. A. KENNEDY

Jelly strength of pectin jells (BAKER) 2. Solubility experiments with boiler metals (JÄRVINEN) 2.

LABARRE, F.: *Manuel du chimiste de laiterie. Analyses de lait et de ses sous-produits.* Paris: Gauthier-Villars & Cie. 168 pp. Fr. 20. Reviewed in *Ind. Eng. Chem.* 18, 216(1926).

TINKLER, C. K., and MASTERS, HELEN: *Applied Chemistry. A Practical Handbook for Students of Household Science and Public Health.* Vol. II—Foods. London: Crosby Lockwood & Son. 276 pp. 15s. net.

Food mixture. E. R. MCSORLEY. U. S. 1,570,443, Jan. 19. A compn. for macaroni and noodles comprises soy bean flour 50 lbs., wheat flour 50 lbs., whole eggs 100, S 1 dram and an alkali such as lime H₂O to form a doughy mixt.

Food from bran, etc. J. L. KELLOGG. U. S. 1,569,861, Jan. 19. Bran or other cereal material is cooked under steam pressure and flavoring substances such as malt, sugar and salt are blown in with the steam during the cooking. Cf. C. A. 20, 462.

Margarine and similar compositions. E. V. SCHOU. U. S. 1,570,529, Jan. 19. An oil-sol. H₂O-dispersing medium derived from fatty oils, e. g., air-blown gelatinized soy oil, is dissolved in an oily constituent such as cottonseed or coconut oil and milk or other aq. constituent is distributed in the oily or fatty constituent until a permanent dispersion is produced.

Manufacture of vitamin-containing foodstuffs with addition of liver oil. P. M. HEYERDAHL. Norw. 41,943, Sept. 28, 1925. The liver oil, preferably from cod liver, is applied in the form of an intimate mixt. with olive oil.

Grained confection. M. A. SCHNELLER. U. S. 1,551,175, Aug. 25, 1925. Dextrose hydrate is melted together with invert sugar and sucrose or other sugars of greater soly. than the dextrose hydrate, in the presence of an amt. of H₂O not substantially greater than is desired in the final product and the mixt. is cooled and seeded with dextrose in cryst. form.

Food for animals from soy beans. L. BERCELLER. Brit. 234,202, March 1, 1924. Soy beans are heated and then subjected to satd. steam for 10-12 min. to remove objectionable constituents. Various details of treatment are given.

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

A review of the heavy chemical industry in 1925. P. PARRISH. *Chem. Age* (London) **13**, 648-50(1925). E. J. C.

Chemical trade movements in 1925. W. G. WILSON. *Chem. Age* (London) **14**, 4-6(1926). E. J. C.

British chemical industry: Developments in 1925. W. J. U. WOOLCOCK. *Chem. Age* (London) **13**, 647(1925). E. J. C.

The heavy chemical industry in 1925. REX FURNESS. *Chemistry & Industry* **44**, 1241-3(1925). E. J. C.

What price progress? HUGH FARRELL. *Separate* (102 pp.) issued by the Chemical Foundation, Inc., N. Y. City, 1925. About the "stake of the investor in the development of chemistry." E. J. C.

What does labor cost in terms of product? A comparison of value of products with wages, salaries and material costs in the chemical engineering industries. C. R. DE LONG. *Chem. Met. Eng.* **32**, 919-21(1925). E. J. C.

The recovery of volatile solvents. J. H. BREGEAT. *Caoutchouc & gutta-percha* **22**, 12939-41(1925).—A criticism of an article by Ditmar on active C (cf. *C. A.* **19**, 3616). Numerous authorities are quoted to show that recovery processes using active C are less economical than those involving absorption in liquids. C. C. DAVIS

Calculation of the various factors in drying, with special reference to brown coal. K. DEIMLER. *Braunkohle* **24**, 853-60(1925).—Tables and charts showing the coal consumption (heat required) for various degrees of drying from various initial percentages of moisture, and giving the yields of (partly) dry substance thus produced. W. B. P.

New methods of gas-washing. IV. Studies on the saturation curves of mixed absorbents. G. WEISSENBERGER, F. SCHUSTER AND O. ZACK. *Z. angew. Chem.* **38**, 1010-3(1925); cf. *C. A.* **19** 3551.—The depression in vapor pressure of MeOAc (I), EtOAc (II), and CHCl_3 (III) was measured at 20° when mixed with phenol and cyclohexanol (IV), or tetrahydronaphthalene (V). Max depression for (I) and (II) was obtained with 2 mols. of phenol with 1 mol. of (V). For (III), 4 mols. of (V) to 1 mol. of phenol gave max. depression. Detailed data are given and discussed briefly. V. Studies with the aid of saturation curves. G. WEISSENBERGER, R. HENKE, AND E. SPERLING. *Ibid* 1164-9.—At 20° decalin (I) and tetralin (II) showed nearly the same absorption of EtOH. For acetone, benzene, and EtOAc, (II) was much better than (I). (II) was better than hydroterpinol (III) for absorbing benzene, acetone, and EtOH. Oil of turpentine, wash oil, (II), and (III) were about equally good absorbents for crude benzene. (II) was a poor absorbent for wood distillate, but when mixed with cresol (3 g. to 7 g. II) a good absorbent was obtained. C. G. KING

Progress made since 1913 in liquefaction of air and in separating atmospheric constituents by liquefaction. C. R. HOUSEMAN. *Proc. Fourth Intern. Congress of Refrigeration* **2**, 995-8(1924). Liquid oxygen apparatus. *Ibid* 998-1002.—Brief description of modern app. for the production of liquid O (Linde and Soc. L'Air Liquide). Purification of air and gases for liquefaction. *Ibid* 1002-6.—A description of the methods used for removal of CO_2 (by CaO and by NaOH) and of the app. used for eliminating the H_2O which condenses and freezes on cooling. Accidents in oxygen apparatus. *Ibid* 1007-10.—Explosions in liquid O app., which occurred when no C_2H_2 was used or stored in or near the plant, were traced to the production of C_2H_2 or of substances with similar properties from the lubricant owing to defective cooling. Lubricating oil with flash point of nearly 600° F. gave C_2H_2 when heated to about 350° C. in air at 30 atm. A. PAPINEAU-COUTURE

Apparatus for separating air into nitrogen, oxygen and argon. H. FILIPPO, JR. *Proc. Fourth Intern. Congress of Refrigeration* **2**, 1218-22(1924).—Brief description of the app. covered by Brit. pat. 101,860. A. PAPINEAU-COUTURE

Chemical engineering during 1925. S. G. URE. *Chemistry & Industry* **44**, 1244-5(1925). E. J. C.

Some methods of estimating quantities, as applied to dams, dumps, etc. F. T. KERR. *Proc. Australasian Inst. Mining & Met.* **1925**, No. 59, 99-106. Quantity estimation of concentrate in dams. A. B. BLACK. *Ibid* 107-14. E. J. C.

Inner Mongolia. B. F. READ. *Pharm. J.* **115**, 570-3(1925).—An illustrated account of travel, referring especially to the niter manuf. in the Chihli province, and the botany, the crops and trade of Mongolia. S. WALDBOTT

Hydrocarbons and their use in refrigeration including some recent discoveries re-

lating to several of their halogen derivatives. ALBERT HENNING. *Proc. Fourth Intern. Congress of Refrigeration* 1, 792-823(1924).—A review of H.'s observations and experience during the last 20 yrs., bringing out more particularly the merits of MeCl and of EtCl. A. PAPINEAU-COUTURE

Gran enciclopedia de química industrial. Química de Muspratt. Vol. 4. Barcelona: Francisco Seix. 960 pp. Ptas 70, bound Ptas 79. Cf. C. A. 17, 1678.

MILLIS, C. T.: **Technical Education, Its Development and Aims.** London: E. Arnold & Co. 182 pp. 6s.

Filtering and sterilizing water, etc. NAAMLLOOZE VENNOOTSCHAAP ALGEMEENE NORIT MAATSCHAPPIJ. *Brit.* 234,149, Dec. 20, 1923. H₂O or other liquid is filtered and sterilized by passing it through a layer of active C which has been treated with gaseous HCl or other innocuous acid or subjected to the action of Cl.

Liquefaction and rectification system for separation of helium from gaseous mixtures. R. R. BOTTOMS. U. S. 1,569,943, Jan. 19.

Compositions for use in refrigerating systems. R. R. STITT. U. S. 1,570,080, Jan. 19. A mixt. comprising MeCl 97½ and MeOH 2½ parts.

Molded heat-insulating material. W. T. IRVIN. U. S. 1,569,755, Jan. 12. Diatomaceous earth is mixed with lime, fiber and H₂O and the mixt. is molded and then hardened and dried by air under pressure.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Water supplies of the communes in the vicinity of Paris. LE COUPEY DE LA FOREST. *La tech. sanit.* 20, 247-8(1925).—Water of the Compagnie des Eaux de la Banlieu is taken from the Seine at Suresnes, put through pre-filters and slow sand filters and chlorinated. JACK J. HINMAN, JR.

Fridley conduit, St. Paul water works. J. W. KELSEY. *Munic. & County Eng.* 69, 70-3(1925).—Water is pumped from the Mississippi River to Charles Lake, a distance of 8 miles. Sixty-inch steel pipe having a semi-rubber base coating was used for the first 8150 feet. The balance of the conduit was constructed of reinforced concrete poured directly in place, with construction joints every 20 feet. C. C. R.

Notes on Toledo's water supply problem. W. J. SHERMAN. *Munic. & County Eng.* 69, 133-5(1925).—Data are presented showing the advisability of the Miami and Erie Canal as a source of Toledo's water supply. C. C. RUCHHOFF

Proposed secondary chlorination of New York water supply after leaving open reservoir at Hillview. WM. W. BRUSH. *J. Am. Water Works Assoc.* 14, 526-31(1925).—The supply, which is surface water, is treated by long sedimentation preceded by and followed by chlorination. Secondary pollution is apt to occur in open reservoirs or in conduits below ground water level, and this must be counteracted by secondary chlorination. D. K. FRENCH

The radioactivity of the water of the thermal spring of Chaudfontaine [Belgium]. EUG. PROST. *Rev. universelle mines* 8 [7], 21-8(1925).—The most recent analysis of the thermal water of Chaudfontaine shows a marked alk. reaction, the presence of Ca, Mg, Fe, Cl, SO₄ and org. material and the absence of NH₄, nitrites, nitrates and H₂S, the compn. by ordinary analysis showing no unusual features. But further expts. revealed the presence of Ra emanation, the content being of the order of 2-3 milli-microcuries per l. The water freed of this emanation by boiling showed a slight activity after several days, though it was not proved whether this were due to residual emanation or to the presence of Ra in the water. C. C. DAVIS

Public-health aspect of stream pollution. J. A. CHILDS. *J. Am. Water Works Assoc.* 14, 578-80(1925).—The effect of pollution on water for domestic use, bathers, ice, etc., is cited, and a study of surface supplies is recommended with the idea of establishing standards as regards permitted contamination. D. K. FRENCH

Differential media for detection of B. coli in water. H. G. DUNHAM, M. H. McCADY AND H. E. JORDAN. *J. Am. Water Works Assoc.* 14, 535-49(1925).—Need for revision of the present standard A. P. H. A. method prompted this work. Brilliant green bile, the principal medium reported on, is considered valuable and worthy of more attention. D. K. FRENCH

Rapid fine-sand filtration. H. W. BLAISDELL. *J. Am. Water Works Assoc.* **14**, 581-97(1925).—An interesting discussion of the various factors in rapid fine-sand filtration. Cost of installation and operation is low; operation is simple; and bacterial efficiency is comparatively high even without alum. D. K. FRENCH

The sterilization by "ferrochlor" of water of rivers used as city supply. NOËL ADAM. *Rev. universelle mines* (Feb. 15, 1924); *Genie civil* **84**, 387-8(1924).—Hypochlorites and FeCl_3 are used. The material added, therefore, contains hypochlorous acid, ferric oxide and a ferrate and is an energetic bactericide. The process has been used for some years at Middlekerk, Belgium, and at Letouze, France. Expts. made at Paris indicate that the dose there would not be more than 4 or 5 g. hypochlorite per cu. m. JACK J. HINMAN, JR.

Separation of small quantities of calcium from large quantities of magnesium in water. H. NOLL. *Chem.-Ztg.* **49**, 1071-2(1925).—Recently the well-known method of sepg. Ca and Mg by means of $(\text{NH}_4)_2\text{C}_2\text{O}_4$ has been subject to criticism and this suggested some expts. with dil. Mg-Ca solns. to see whether values obtained in water analyses by the conventional method were really accurate. Some 65 careful expts. show that the oxalate method is indeed satisfactory in water analysis provided the sepn. is effected in 200 cc. of the water when not over 125 mg. of MgO is present. W. T. H.

Methods for the determination of oxygen dissolved in water in the presence of nitrous acid. G. ALSTERBERG. *Biochem. Z.* **159**, 36-47(1925).—To eliminate the disturbing effect of N_2O_5 in the detn. of dissolved O, hydrazoic acid is used. ($\text{N}_2\text{O}_5 + 2\text{HN}_3 = 2\text{N}_2\text{O} + 2\text{N}_2 + \text{H}_2\text{O}$.) Solns. contg. alkali or mineral acid must be used to prevent the reaction $2\text{NaN}_3 + 2\text{I} = 2\text{NaI} + 3\text{N}_2$ from taking place. The rest of the detn. is the same as that of Winckler. In the presence of small quantities of N_2O_5 , the HN_3 may be added after the pptd. MnO_2 is dissolved in H_2SO_4 . The reagent has the following compn.: 3 g. NaOH, 20KI and 0.5 g. NaN_3 in 100 cc. solu. One cc. is used in a test for O. W. D. L.

Determination of oxygen dissolved in water in presence of nitrite. M. F. STAS. *Chem. Weekblad* **22**, 584-5(1925); cf. *C. A.* **7**, 4026.—Alsterberg's method (cf. preceding abstr.) gives accurate results provided the water is treated with NaN_3 before the liberation of I. The NO_2 content of sewage waters, even of very impure ones, does not exceed 8 mg./l., so that 10 mg. NaN_3 is sufficient. MARY JACOBSEN

Chemical supervision of plants for softening of boiler water. A. SPLITTERBERG. *Z. Nahr. Genussm.* **50**, 142-77(1925).—A review, with an extensive bibliography, of the soda, lime-soda and permutite processes, including a discussion of methods of detn. and allowable limits of various impurities. WILLIAM J. HUSA

The alkalinity of boiler feed water. KOIRANSKY. *Chaleur et industrie* **6**, 563-4(1925). J. SALLE. *Ibid* 563-4.—Polemical against Bru (*C. A.* **19**, 3136). A. P.-C.

The problem of sewage disposal in the Ems and Ruhr territory. JAN SMIT. *Chem. Weekblad* **22**, 537-41(1925).—The problem is particularly difficult because of the dense population, the network of coal mines and industrial plants and the continuous settling of the ground, which counteracts drainage. The river Ems is used as a canal to carry the sewage to the Rhine before the rotting sets in. Its bed has been raised to secure a shortcut; a high dam at the mouth makes it independent of the water level of the Rhine and protects the low country from being flooded. Before entering the Ems the water is freed from most of the org. floating matter in the highly efficient tanks, the "Emscherputten." The 400 tons daily of inorg. sludge from the coal mines are collected and dried in the mines and partly used as admixture to cheap fuel. The phenols and chlorophenols from the gas, coke and other industries threaten the fisheries, not so much by a direct toxic effect as by impairing the taste of the fish. They are removed from the sewage water by biol. oxidation on porous surfaces and aeration according to Fowler and Bach or extd. with benzene from the gas water. MARY JACOBSEN

Filter for water (U. S. pat. 1,570,523) 1. Filtering and sterilizing water (Brit. pat. 234,149) 13.

KERSHAW, G. BERTRAM: *Sewage Purification and Disposal*. 2nd ed. revised. London: Cambridge University. 18s.

Treating aluminosilicate minerals for water-softening. HERMAN REINHOLD. U. S. 1,570,006, Jan. 19. Minerals of the bentonite variety are ground, sized, calcined, treated with a sol. Al compd. such as $\text{Al}_2(\text{SO}_4)_3$, NaOH and NaCl and excess moisture is dried out.

Apparatus for deaerating boiler feed-water, etc. GRISCOM-RUSSELL Co. Brit. 234,448, May 24, 1924. A portion of the incoming liquid is distributed in the app. in the form of a curtain of falling drops through which the evolved gases and vapor pass to condense the latter.

Float signal device for indicating the presence of oil in boiler feed-water, etc. T. A. SHORT. Brit. 234,453, May 24, 1924.

Treating garbage. E. H. BRUNE. Brit. 234,700, Oct. 27, 1924. Liquids are pressed from green garbage and it is ground to a pulp which may be used for an animal or poultry feed or as a fertilizer. The liquid is heated to coagulate albuminoids. Oils and fats are sepd. and may also be used as animal foods. Cf. C. A. 19, 369.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

Johnson County soils. R. S. SMITH, E. A. NORTON, E. E. DE TURK, F. C. BAUER AND L. H. SMITH. Illinois Agr. Expt. Sta., *Soil Report* No. 30, 40 pp.(1925).—An invoice of the elements of plant food in the soil types of the county is given, together with a rept. of fertilizer expts. J. J. SKINNER

Mercer County soils. R. S. SMITH, E. E. DE TURK, F. C. BAUER AND L. H. SMITH. Illinois Agr. Exp. Sta., *Soil Report* 29, 64 pp.(1925).—A general rept. on the soils of the county, giving soil classification, chem. analysis and results of fertilizer expts. J. J. SKINNER

Analysis of soils of Rabun County. L. M. CARTER, M. W. LOWRY, W. O. COLLINS, R. M. SOULE AND G. L. FULLER. Georgia State Col. Agr., *Bull.* 308, 24 pp.(1925).—The chem. analysis of 11 soil types of the county are given. J. J. SKINNER

Irrigation with special reference to the economic use of water. H. W. TURPIN. *J. Dept. Agr. Union S. Africa* 11, 436-54(1925).—A correlation of published data on the effect of irrigation on the soil and on the compn. and yield of various crops. K. D. J.

Condensation of water in the ground. J. VERSLUYS. *Water en Gas* July 3, 1925, 144; *Water and Water Eng.* 27, 381(1925).—Condensation of gases by adsorption takes place on the surface of solid bodies and is most intense in capillary spaces. Here water may condense from soil air though it may not be satd. at the temp. Between the adjacent grains a drop with a concave surface forms and increases in size until equil. has been attained. These drops probably do not fuse and flow into the ground water, but they are probably available to rootlets of plants which, by their absorption of the water, disturb the equil. and induce further condensation. JACK J. HINMAN, JR.
